The past month has been a disastrous one to our bees. I lost 6 colonies since March 9, that were then in good condition; they left hatching brood, eggs, larvae and *new* honey. I see no cause for their dying. I have 12 colonies left, all in good condition, though some are not very strong. I put away 23 colonies. The spring has been very cold, wet and windy—bad for bees. Mrs. MYRA L. PARSONS.

Linwood, Mich., May 7, 1883.

Done Again.

I wintered 29 colonies of bees in the cellar safely, and without the loss of a single colony. They were there 141 days without a chance to fly. I gave them upward ventilation. The temperature of the cellar was from 33° to 41°. They did not breed in the cellar. Willow is now in full bloom and all is lovely. The Syrian bees take the lead. I notice that some enquire why their bees swarm out, leaving honey and brood. My advice is: Do not open the hive and handle the frames, if the colony is weak.

F. LEE.

Cokato, Minn., April 27, 1883.

Bees Gathering Honey.

Being away last fall, my bees were not properly prepared for winter. I have 24 colonies in very fine condition. They have gathered some honey. My loss was 10 colonies.

JOHN MEADER.

Delaware, Iowa, May 11, 1883.

Bereaved.

Last Friday morning a telephone message called me to Grand Rapids to the bedside of the "queen" of my household, who has been suffering for the past 15 months with that dreadful disease, cancer. She welcomed me on getting there, but passed to that other world beyond us, and into that "better life," at 7 o'clock Sunday evening. Yesterday (Wednesday) we brought her earthly remains to Muskegon, and laid them beside her father and mother, after six years of happiness.

GEO. E. HILTON.

Fremont, Mich., May 10, 1883.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL,
Monday, 10 a. m., May 14, 1882.

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—The nominal price of extracted is 7c. for dark and 9c. for light—here. The supply is abundant and sales are slow.

BEESWAX—None in the market.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The demand for extracted honey is very good, and arrivals are slow. We pay 7 $\frac{1}{2}$ to 10c. on arrival. We sold, since last October, more than 600 barrels, and our stock is exhausted, while our customers are relying on us for supplies. Hope our friends will supply us. No demand for comb honey, and prices nominal.

BEESWAX—Arrivals of beeswax are good, and prices range from 30 $\frac{1}{2}$ to 33c. for a good article.

CHAS. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand is light and it is not now probable that all of the comb honey can be sold before a new crop comes. Prices are very irregular and generally low. 15c. to 16c. for white, and dark unsalable. Extracted, very little trade is being done in it. 7 $\frac{1}{2}$ to 9c. is about the market.

BEESWAX—30 $\frac{1}{2}$ to 33c.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Stocks and the demand are both light. More or less difficulty would be experienced in filling a large order for a straight lot. White comb, 14 $\frac{1}{2}$ to 17c.; dark to good, 11 to 13c.; extracted, choice to extra white, 8 $\frac{1}{2}$ to 9 $\frac{1}{2}$ c.; dark and candied, 5 $\frac{1}{2}$ to 7 $\frac{1}{2}$ c.

BEESWAX—Wholesale, 27 to 28c.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Bulk, light jobbing sales only. Comb at 10 $\frac{1}{2}$ to 14c.—Strained and extracted at 7 to 7 $\frac{1}{2}$ c. Couple lots of poor Comb sold at 10c.

BEESWAX—Sold lightly at 35 to 36c.

W. T. ANDERSON & CO., 117 N. Main Street.

CLEVELAND.

HONEY—Stocks of honey are running low with us. 1-lb. sections are all sold and there is a very light inquiry for such; would probably sell at 18 to 20c. 2-lb. sections are not in demand, and no sales to quote, asking 17 to 18c. Extracted no sale at the 10c.

BEESWAX—Not offering.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—Our market is fairly active. We quote: $\frac{1}{2}$ lb. sections at 30 $\frac{1}{2}$; 1 lb. sections, 22 to 25c.; 2 lb. sections, 20 to 22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.

BEESWAX—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatham Street.

Price Lists.—The following Price Lists for 1883 are on our desk:

S. Valentine & Son, Hagerstown, Md.

E. A. Thomas & Co., Coleraine, Mass.

E. S. Hildemann, Ashippun, Wis.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
" 100 colonies (220 pages).....1 50
" 200 colonies (420 pages).....2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Our stock of back numbers of this volume are now getting very low. Please look over your numbers, and if any are lacking, send us a postal card, giving the date of those you want, and we will send them, if not all gone. We give this notice, because, last year, several left it until the end of the year, and then requested us to send the missing numbers. Then it was too late, the numbers being all gone. Look them over now, and you may get them completed.

Foul Brood Pamphlet.—Wishing to be relieved of sending out my pamphlet on Foul Brood, I have made arrangements with Mr. T. G. Newman to supply them to the bee-keeping fraternity desiring them.

A. R. KOHNKE.

Youngstown, O., April 25, 1883.

Mr. Alley's new book on Queen Rearing will hereafter cost \$1.25

Cyprians Conquered.

All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am "boss." Bingham's "Conqueror Smoker" did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham.

G. M. DOOLITTLE.

Borodino, N. Y., Aug. 15, 1883.

18A4t 5B1t

We have a few copies of our pamphlet entitled "Bee Culture" left, and have reduced the price from 40 to 25 cents each, or \$2 per dozen.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Special Notice.—We will, hereafter, supply the Weekly BEE JOURNAL for 1883 and Cook's Manual in cloth for \$2.75, or the Monthly and Manual in cloth for \$1.75. As this offer will soon be withdrawn, those who desire it should send for the book at once.

Do not let your numbers of the BEE JOURNAL for 1882 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

May we ask you, dear reader, to speak a good word for the BEE JOURNAL to neighbors who keep bees, and send on at least one new subscription with your own? Our premium, "Bees and Honey," in cloth, for one new subscriber to the Weekly, or two for the Monthly, besides your own subscription to either edition, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

THOSE WHO WANT

Hybrid or Black Queens,

TAKE NOTICE.

We have bought a large number of Hybrid and Black Colonies of Bees which have fine Queens. These Queens we will sell at 50 cts. for Blacks, and 75 cts. for Hybrids. Notice our advertisement of ALBINO AND ITALIAN QUEENS, etc., in the April or May numbers.

Address—S. VALENTINE & SON, HAGERSTOWN, MD.

THE BRITISH BEE JOURNAL AND BEE-KEEPER'S ADVISER.

The BRITISH BEE JOURNAL is published monthly, and contains the best practical information for the time being, showing what to do, and when and how to do it. Rev. H. R. PEEL, Editor.

We send the Weekly AMERICAN BEE JOURNAL and the British Bee Journal, both for \$3.00 a year.

1000 Colonies of Italian and Hybrid bees for sale in Langstroth and Simplicity hives.

Three-Frame Nuclei a specialty. Safe delivery guaranteed. Write for particulars and special rates to

FLANAGAN & ILLINSKI,

Box 819, BELLEVILLE, St. Clair Co., ILL.
17A4t 5B2t

A NEW BEE BOOK!

BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN,

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most honey in its best and most attractive condition.

Appreciative Notices.

A neat and abundantly illustrated hand-book of apiculture.—American Agriculturist, N. Y.

Its chapter on marketing honey is worth many times its cost.—Citizen, Pulaski, Tenn.

Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of every beginner with bees.—News, Keithsburg, Ill.

Valuable for all who are interested in the care and management of bees.—Dem., Allegan, Mich.

Engravings are fine. Gotten up in the best style, and is cheap at the price.—Farmer, Cleveland, O.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in this line.—We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—Farmer, Lancaster, Pa.

PRICE—Bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

THOMAS G. NEWMAN,

925 W. Madison St., Chicago, Ill.

1883.

YOU GET VALUE RECEIVED!

1883.

QUEENS, BEES AND SUPPLIES

If you want EARLY QUEENS from the best improved genuine stock for business; or if you want Imported Italian Queens or bees, in full colonies or nuclei, with tested or untested queens; if you want Dunham or Vandervort come foundation, made from pure beeswax; or if you want hives or apiarian supplies of any kind, send for my new catalogue. It tells you about introducing queens, new "Races of Bees," etc. Cash paid for clean beeswax. Address—

5BD15t

J. P. H. BROWN,
Augusta, Georgia.

BE SURE

To send a postal card for our Illustrated Catalogue of Apiarian Supplies before purchasing elsewhere. It contains illustrations and descriptions of everything new and valuable needed in an apiary, at the low prices. Italian Queens and Bees. Parties intending to purchase bees in lots of 10 Colonies or more are invited to correspond.

51D15tB3t

J. C. SAYLES,
Hartford, Wis.

ELECTROTYPES

Of Engravings used in the Bee Journal for sale at 25 cents per square inch—no single cut sold for less than 50 cts.

BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Adulteration, a Root of Bitterness.

One of our correspondents writes us as follows:

Prince Bismarck says that American pork and lard are the "root of all evil," and that it is fattening the grave-yards with human beings.

At East Buffalo, N. Y., are the great hog yards fed on the refuse of the grape sugar factories; there are others at Lawrence, Peoria, and Des Moines, where the hogs and cattle are covered with boils. Adulteration is the root of much evil, in America.

The California *Canner and Grocer* remarks as follows:

If some means is not soon devised to check the alarming tendency to food adulteration, there will, in a short time, be but little market for our goods abroad. It is to be regretted that manufacturers cannot be made to see that any policy, except that which grants a pure article at a fair profit, defeats itself in the end, and that an adulterated article placed upon a foreign market, bearing the label of an American firm, inflicts an irreparable injury upon American manufacturers. This should be made the gravest kind of a misdemeanor, and those driven to such courses through their inordinate greed, should meet with speedy and condign punishment. With our present manufacturing interests, we need an European market as an outlet for our goods. Increasing as our manufactures are, it is of vital importance that foreign markets should be kept open to us. That they will not be, we have every reason to expect, unless some means is soon found of checking the adulteration of goods, and the counterfeiting of brands, to enable the placing of inferior goods. The foregoing remarks are suggested by the recent action of the Cuban Government in reference to importations of American lard into the port of Havana. The Collector of Customs of that port has been instructed to refuse admit-

tance to four brands of this American lard, until they have each been the object of a rigid scientific examination. The charge of adulteration is entered against them, and the adulterant is thought to be injurious.

The *Canner and Grocer* continues by saying, "Adulteration is the thief of trade. More tempting than Delilah, for it woos with promises of golden gains; it finds numberless lovers among those who deal in the staple-food articles of commerce, and lures them on from bad to worse, until finally they become hopelessly entangled in a net-work of dishonest practices. Under our at-present imperfect laws for protection against the sale of spurious goods, with but slight danger of detection, and with a certainty of large profit, many a dealer, finding his keener sense of honor dulled by money greed, begins to adulterate the commodities he keeps for sale, and thus enters into a career that is more villainous and more dangerous to the community than that of the old-time highwayman; for through it the public are robbed not only of their coin, but of their health as well.

"This infamous system has been growing of late with frightful rapidity until one is in almost perpetual fear lest he be eating or drinking some poisonous compound instead of the healthful article which it counterfeits. This vile traffic is confined to no locality or country, but is pursued in all the business centres of the civilized world, and from them finds its way into the most distant channels of trade. As an evidence that this evil exists in many of the ramifications of trade, let us glance at the report of the New York Board of Health, they having been investigating the matter of late: "Out of 236 samples of oils examined, the committee reported that only 32 stood the test provided by law. Seventy-five samples of drugs were examined, and 32 found to be adulterated. Samples of food to the number of 119 were examined, 60 of which were found to be in similar condition."

Organized efforts are being made in several countries to check or put a stop to this adulteration of food and other necessities of daily use, but so far they have met with only partial

success, excepting in the case of Germany, where the good work goes bravely on, and its excellent results are already proven. The English system is acknowledged to be unsatisfactory. Dr. Wigner, Public Analyst, wrote in 1881:

"These statistics, unfortunately, prove that our legislation is not perfect, but, on the contrary, that the rate of adulteration prevailing now, although a vast improvement over the condition of things prior to the passage of the acts, does not show a continued decrease."

In referring to this subject Prof. Charles R. Fletcher, of Boston, said:

"While in England 17,000 samples of food were analyzed in a year, one finds over 231,000 samples examined in Germany. The German law is rigid, and receives vigorous Government and individual support, and if anybody would examine an approach to an effective system, I think he should turn to Germany."

We are glad to learn that, in New York city, the Board of Health is putting the new adulteration law in vigorous force, and the result of its investigations has been the commencement of numerous prosecutions against dishonest manufacturers and tradesmen. There are some complaints, it is true, that these have been instigated by rival houses, etc., but even if that be so, the public have reason for congratulation. An Exchange aptly remarks that it "would be better, for instance, that the courts should punish burglars even to the verge of inquisitorial persecution, and at the same time allow sneak-thieves to go unprosecuted, than that they should, for the sake of ill-named justice, allow both of these rascally classes to go unscathed. Every case of adulteration punished is a victory gained for honest trade in general, no matter from what branch of business the offenders may have been selected."

Adulteration of honey, as well as all kinds of food, should be strongly condemned, until strong, well-defined and rigidly-enforced laws shall give full and permanent relief to all innocent purchasers and consumers.

Bee-Pastures of Mount Shasta.

The *Century* contains the following interesting descriptions of the bee-pastures of Mount Shasta, in the Sierras of the far west:

Shasta is a fire-mountain, created by a succession of eruptions of ashes and molten lava, which, flowing over the lips of its several craters, grew outward and upward like the trunk of a knotty exogenous tree. Then followed a strange contrast. The glacial winter came on, loading the cooling mountain with ice which flowed slowly outward in every direction, radiating from the summit in the form of one vast conical glacier—a down-crawling mantle of ice upon a fountain of smoldering fire, crushing and grinding for centuries its brown, flinty lavas with incessant activity, and thus degrading and remodeling the entire mountain. When, at length, the glacial period began to draw near its close, the ice-mantle was gradually melted off around the bottom, and, in receding and breaking into its present fragmentary condition, irregular rings and heaps of moraine matter were stored upon its flanks. The glacial erosion of most of the Shasta lavas produced a detritus, composed of rough, sub-angular bowlders of moderate size and porous gravel and sand, which yields freely to the transporting power of running water. Under Nature's management, the next marked geological event made to take place in the history of Mount Shasta, was a water-flood of extraordinary magnitude, which acted with sublime energy upon this prepared glacial detritus, sorting it out and carrying down immense quantities from the higher slopes, and re-depositing it in smooth, delta-like beds around the base; and it is these flood-beds of moraine soil, thus suddenly and simultaneously laid down and joined edge to edge, that now form the main honey-zone.

Thus, by forces seemingly antagonistic and destructive, has Mother Nature accomplished her beneficent designs—now a flood of fire, now a flood of ice, now a flood of water; and then an outburst of organic life, a milky-way of snowy petals and wings, girdling the rugged mountain like a cloud, as if the vivifying sunbeams beating against its sides had broken into a foam of plant-bloom and bees.

In this lovely wilderness the bees rove and revel, rejoicing in the bounty of the sun, clambering eagerly through bramble and hucklebloom, stirring the clustered bells of the manzanita, now humming aloft among polleny willows and firs, now down on the ashy ground among gillias and buttercups, and anon plunging deep into snowy banks of cherry and buckthorn. * * * The Shasta bees are perhaps better fed than any others in the sierra. Their field-work is one perpetual feast; but, however exhilarating the sunshine, or bountiful the supply of flowers, they are always dainty feeders. Humming-moths and humming-birds seldom set foot upon

a flower, but poise on the wing in front of it, and reach forward as if they were sucking through straws. But bees, though as dainty as they, hug their favorite flowers with profound cordiality, and push their blunt, polleny faces against them, like babies on their mother's bosom.

Planting for Honey.

The value of an apiary is determined not by the number of the colonies it contains, but by the strength of the colonies, and their availability for work. If there is no pasturage the best bees in the world must be idle. If but little honey bloom is provided for the bees to gather from, then but little honey will be the result. Hence the necessity of providing pasturage for the bees during the whole season. "Planting for honey" is the key to the situation.

Speaking of the honey dearth between fruit bloom and white clover, when the bees hardly obtain enough honey for daily use, the *Indiana Farmer* says: "To our mind this is the most important dearth which the bee-keeper must strive to bridge over by planting. The stimulus given the bees by fruit bloom should, if possible, be kept up until the coming of white clover, so as to have them in the best possible condition when the harvest comes." This is evidently the truth in a nutshell. To obtain something to fill this gap is the one point that should engage the attention of every apiarist.

Continuous bloom means continuous honey gathering, and a continuous flow of money into the bee-keepers' pockets.

A "Good" Man Going South.—Mr. F. L. Dougherty, of Indianapolis, says: "While waiting at the depot a few days since, we happened upon friend I. R. Good, of Nappanee, Ind. Mr. Good is a queen rearer of some note, but lost heavily of bees during the past winter. Out of 225 colonies put into winter quarters only 80 survived, many of them being in a weak condition, those in the cellar suffering as much or more than those wintered on the summer stands. Mr. Good has decided to move his bees south, and after considerable search has picked on a location near Tullahoma, Tenn. He thinks he will not be able to do anything in the way of queen rearing this season, except for his own use. His brother will have charge of the Tullahoma apiary the present season.

Queens will be reared here and shipped to Tullahoma for the purpose of fully stocking the apiaries there, while Mr. Good again stocks the home apiary. He is inclined to think the bee and queen trade is turning to the south, as they can there be got into better condition so much earlier in the season."

"The Doctor."—Another arrival at our Museum is "The Doctor," which is a large bellows bee smoker—the largest we ever saw—consisting of a fire box $3\frac{1}{2}$ inches in diameter. Its gust of wind is tremendous, and the volume of smoke from it would instantly subdue the most vicious bees in existence. It is made by Bingham & Hetherington, Abronia, Mich.

Signs of Swarming.—Mr. F. L. Dougherty, in the *Indiana Farmer*, gives the following on this subject:

There is no certain method of judging, from out-side appearances, as to just when a colony is going to swarm. The most general indications noticeable from the out-side of the hive that they are preparing to swarm are the inactivity of the bees, hanging in clusters about the entrances, and pollen gatherers hanging with the cluster instead of entering the hive. However, they may be prepared to swarm with queen-cells built; then, because of unfavorable weather, or a slight cessation of the honey flow may suddenly destroy the cells and give up all attempts to swarm. Or they may soon again commence preparations, wasting a very great part of the honey crop, for they seldom do but little good gathering honey while the swarming fever is on. Just here is where the knowledge of the scientific bee-keeper comes to his help. As the bees are just in the right condition to divide, he divides them at once without farther waiting. Bees will at times, if left to themselves, throw off as many as five or six swarms, each one smaller than the preceding. The old queen leaves with the first swarm. All after swarms contain young queens. Where honey is the object, colonies should not be allowed to cast but one swarm, as a very rapid increase can seldom be accomplished except at the expense of the honey crop. With the movable frame it is but little trouble to prevent this by simply opening the hive 7 or 8 days later and removing the extra queen-cells. With box hives, the only plan is to place the hive containing the first swarm, on the old stand, moving the old hive to a new location, thus depleting its strength to such an extent that it will not want to swarm any more. Before swarming, bees usually gorge themselves with honey, and while in this condition can be handled almost with impunity, yet care should always be used, that no bees be mashed or they may take the notion to make it very unpleasant for the manipulator.

The Coming Bee.—The following very amusing sketch of the troubles incident upon removing bees from cellars, is from *Gleanings*, by Eugene Secor, Forest City, Iowa. On April 17, 1883, he wrote as follows:

This subject has been discussed so many times that I should not touch it, were it not from the fact that I have seen it. I saw it yesterday. In fact, I saw several of them. They saw me, too—I mean some of them did, and the rest felt for me, and they found me. I felt them without feeling for them either. My feeling so pleased them that they called in their sisters, cousins and aunts, to feel of me also. They came, they saw, they felt. I felt, too—in fact, I feel yet.

This is how I came to see,
And feel the points of the coming bee.

They were in the cellar, where they had been for only the short period of 157 days and nights, amiable, gentle Italians, as I supposed when I tucked them in their little beds in the fall. My cellar was dark. They could not see; so I suppose they had got accustomed to feeling. May be that accounts for the fellow-feeling they manifested for me. I carried out colony No. 1, *sans* hat, *sans* coat, *sans* gloves. The "coming bee" at once dawned upon my vision. She felt of my hands, felt of neck, felt of my hair, and felt of my whiskers. She sang a song in bee-sharp which attracted all her female acquaintances. They improvised a jubilee concert on the spot. I was the only interested auditor; and as soon as I could "unload my stock," I "clapped." They appreciated the cheering, and sang louder. They called in some of their finest Italian opera-singers and performers. That music is not usually understood in this country. The clapping is generally done because it is fashionable to applaud everything that is foreign. But I understood every demi-semi-quaver. I clapped with the spirit and with the understanding also. But I felt that they were expending too much talent on such a small audience, so I retired as gracefully as the overwhelming attentions being paid me would allow.

Intermission of 15 minutes. Curtain drops.

It is usually customary for the actors to change costumes while the curtain is down. In this instance, however, the audience changed dress. The next act begins when I carry the second colony out of the cellar. This time I am prepared for the coming bee. Armed with straw hat, bee-veil, and gauntlet gloves, I looked like a cross between a knight-errant, a sister of charity, and an honest granger. With my gauntlets drawn snugly around the arms with rubber cord, and the veil ditto around the neck, now let 'em sing, sang I. They sang again; and as the wind gently pressed the tarlatan against my nose, one of the foremost of the Italian singers sat down to rest on the ornament part of my face. As I had no one to help me let go of the hive I was carrying, and as I was in somewhat of a hurry, I allowed the Italian miss to

keep her seat. All at once she doubled up like a boy who has eaten too many green cucumbers; and as if afraid of falling off, she drilled my proboscis with her little gimlet. Others of her companions, hearing of her distress, came to see what was the matter, and sat down also. And as there was not sitting room on my front porch for all the sympathizing friends, some of them crowded between my veil and the place where my shirt collar ought to have been, and came up on the inside for a closer interview. By the time I had reached the yard, my neck felt as if I had undergone treatment for sore throat with counter-irritants. Then if you ever saw a cat trying to pull a mitten off its head with its fore paws, you can imagine how dignified I looked. Instead of being the audience, I was now one of the chief performers, while my wife, sitting in the bay-window, was the interested and amused spectator, enjoying the show as much as our boys did Barnum's Hippodrome. I created as much interest as a whole menagerie, when the animals had just been "stirred up." The performance lasted only about an hour, and closed amid the wildest enthusiasm.

Don't talk to me about the *Apis dorsata*. If their *gimlets* are any longer than the ones I felt, I'll be excused from buying any. Tell Mr. Jones he had better call Frank Benton home. I have lost all interest in the "coming bee."

Dzierzon's Rational Bee-Keeping.

Gleanings, in bee-culture, gives this book the following notice:

Mr. Newman has kindly sent us a work entitled "Rational Bee-keeping," by our old father Dzierzon, the originator of the theory bearing his name. The author is not only a thoroughly scientific bee-keeper, but a naturalist. He has probably made greater strides in scientific apiculture than any one man. His book contains his many discoveries, together with his valuable experience and research. In addition to this are foot-notes by C. N. Abbott, the former editor of the *British Bee Journal*. We thus have the opportunity of direct comparison and verification. As regards the nature, the distinctive characteristics and explanation of some of the peculiar phenomena noticed in bees, the book seems to stand among the foremost, if not in the front ranks. I hardly think the implements of the apiary would be at all suited to American bee-keepers; but as for real scientific value, it would well repay any bee-keeper whose attention is at all inclined to scientific research, to purchase a copy. It contains 350 pages, fully illustrated.

We can mail it to any address for \$2, bound in cloth, or \$1.75 in paper covers.

Articles for publication must be written on a separate piece of paper from items of business.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL,
Monday, 10 a. m., May 21, 1882.

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—The nominal price of extracted is 7c. for dark and 9c. for light—here. The supply is abundant and sales are slow.

BEESWAX—None in the market.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The demand for extracted honey is very good, and arrivals are slow. We pay 7½c. on arrival. We sold, since last October, more than 600 barrels, and our stock is exhausted, while our customers are relying on us for supplies. Hope our friends will supply us. No demand for comb honey, and prices nominal.

BEESWAX—Arrivals of beeswax are good, and prices range from 30¢ to 35¢, for a good article.

CHAS. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand is light and it is not now probable that all of the comb honey can be sold before a new crop comes. Prices are very irregular and generally low: 15¢ to 16¢ for white, and dark unsalable. Extracted, very little trade is being done in it. 7¢ to 9¢ is about the market.

BEESWAX—35¢ to 36¢.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Stocks and the demand are both light. More or less difficulty would be experienced in filling a large order for a straight lot. White comb, 14¢ to 17¢; dark to good, 11¢ to 13¢; extracted, choice to extra white, 8¢ to 9¢; dark and candied, 5¢ to 7¢.

BEESWAX—Wholesale, 27¢ to 28¢.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Dull; light jobbing sales only. Comb at 10¢ to 14¢.—Strained and extracted at 7¢ to 7½¢. Couple lots of poor Comb sold at 10¢.

BEESWAX—Sold lightly at 35¢ to 36¢.

W. T. ANDERSON & Co., 117 N. Main Street.

CLEVELAND.

HONEY—Stocks of honey are running low with us. 1-lb. sections are all sold and there is a very light inquiry for such; would probably sell at 18¢ to 20¢. 2-lb. sections are not in demand, and no sales to quote, asking 17¢ to 18¢. Extracted no sale at 9¢ to 10¢.

BEESWAX—Not offering.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—Our market is fairly active. We quote: ½ lb. sections at 30¢; 1 lb. sections, 22¢ to 25¢; 2 lb. sections, 20¢ to 22¢. Extracted, 10¢ per lb. Good lots of extracted are wanted in kegs or barrels.

BEESWAX—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatham Street.

The Southwestern Iowa Bee-Keepers' Association will hold its annual meeting at the apiary of L. E. Mercer, Lenox, Taylor county, Iowa, May 26, 1883. Meeting called at 10 o'clock sharp. Forenoon: Election of officers. Afternoon: Work in the apiary, when any question, with regard to handling bees, will be practically explained. Accommodations will be provided for visitors from a distance. W. J. OLIVER, Sec.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

For the American Bee Journal.

Uniting Bees—Spring Management.

G. M. DOOLITTLE.

I am requested by several to give, in the BEE JOURNAL, my plan of uniting bees, and I will try to do so; if I do not make it all plain, I will further explain if necessary.

We are often told, that if our bees are weak in March or April, we should unite them at once, putting two or more together, till a fair colony is formed. I formerly adopted this plan until I ascertained from many experiments, that colonies thus made were no better at the end of three or four weeks, than each would have been had they been left separated. If I had colonies that would not live till June separately, I found they would not if united. I have put as high as six or seven very weak colonies together, in April, thus making a good large colony at the time, and in a month all were dead. Hence, I came to the conclusion that I could not

unite my bees profitably early in the season, so I have adopted the following, which has proven very successful:

About the middle of April, according to the season (earlier if any early season, and late if a late one), some cold morning I look over all my bees, by taking off the cap and lifting the quilt a little, and all that do not occupy five spaces between the combs are marked, and the first warm day I shut them on to as many combs as have brood, by means of a division-board. Those which are very small, so as to have brood in only one or two combs, and small patches at that, have all their extra combs taken away from them, so as to take precaution against robbing; but if stronger, I leave the extra combs on the other side of the division-board, so that the bees can carry the honey over as they need it for brood-rearing.

The entrance to each hive is contracted to suit the size of the colony, not leaving more than an inch in length for the best of them, and only space enough for one bee to pass at a time for the weakest.

The next work is to increase the brood as fast as possible in these small colonies. I keep them on the combs, first given them, till they are filled with brood clear to the bottom, when I give them an empty comb, placed in the centre. This will be filled in a week or so, when another is given. I go over them once a week, in this way, till I have five frames full of brood in the strongest. The next time I go over them, I take a frame of brood just hatching from those having the five filled, and give it to the next strongest (say one that has four frames), putting an empty comb in the place where it came from, and so keep working until each hive contains five frames crowded with brood.

Do not make the mistake of giving the frame of hatching brood to the weakest colonies first, for they may not be strong enough, if the weather should suddenly become cool, to care for it; when a loss of brood, to the amount given, might occur.

By the middle of June, I generally get all in the above condition, when they are ready for uniting. To do this, I go to No. 1 and open it; look the frames over until I find the queen, when I set the frame she is on outside of the hive; then take the four remaining frames (bees and all) to No. 2, spread the five frames apart in No. 2, and put the four frames taken from No. 1 in each alternate space, made by spreading the frames in No. 2. I now close up No. 2, and in 12 or 15 days it will be one of the strongest colonies in the yard.

By alternating the frames, the bees are so mixed up that they will not quarrel, and I have never known a queen to be harmed. It will be seen that I use but nine frames to the hive, but the plan is the same with any number of frames. I now return to No. 1, where the frame of bees was left standing outside of the hive, close to one side, and put in an empty frame; adjust the division-board, and I have a nice nucleus to get a queen from at any time I may need one. I

find also, that such a nucleus will build comb almost as cheaply as foundation can be gotten into comb; for many of the old bees taken to No. 2 will return, thus making a strong nucleus, which will build nice straight worker combs, as if by magic. If I do not wish these for queens or comb building, I build them up to good strong colonies by the fall.

UNITING IN THE FALL.

If I wish to unite bees in the fall, on account of there being but little honey, fewness of bees, or from whatever cause, the first thing to find out is, which of the two has the most valuable queen. Having ascertained this, I hunt up the poorest and kill her, then take this hive to the stand of the one it is to be united with. I now select from the two frames having the most honey in them, to the number I wish to winter them on, and set them in one of the hives, alternating them, as they are set in the hive. I next shake the bees, which are on the remaining frames, off at the entrance, taking one frame from one colony, and the next from the other, so as to mix the bees up as much as possible.

When all the bees are inside the hive, the work is done. Remove the hive, bottom board and all, from the stand occupied by the united colony, and no loss of bees will occur. What few bees go back to the old stand, return after finding their old hive is gone; also the mixing up process causes them to mark their location anew, at their first flight afterward.

Borodino, N. Y.

For the American Bee Journal.

Bees as Aids to Fruit Growers.

J. F. LATHAM.

In the agricultural column of a weekly paper, I find a "clip" credited to another journal, from which the following is an extract:

"Honey is a vegetable production, appearing in greater or less quantities in every flower that nods to the breeze, or kisses the bright sunlight.

* * * It is secreted in the flower for the purpose of attracting insects, thus securing the complete fertilization of the female blossoms."

The declaration embodied in the last sentence of the foregoing extract, is new to me; as, heretofore, I have understood the nectar of flowers to be a menstruum, surplus secretion, excess of growth, etc., drawn from the soil and atmosphere, which, after the necessary operations of assimilation, and contribution to the requirements of vegetable growth are accomplished, is conveyed to and lodged in the chalice of the pistillated bloom by capillary process, and can, therefore, be no more or less than waste matter, so far as needed to further enhance the growth of fruit or seed.

That the nectar in flowers is an aid to their fertilization (in a general way), by inducing insects to distribute the fecundating element from the staminate blossoms, by conveying it

on their bodies during their flights among the flowers, while collecting the exuding sweets, is evident; that this is the sole object for which nectar is secreted does not seem admissible.

Pollen is borne from flower to flower on the breeze as well as on the bodies of insects; in fact, that appears to be nature's prime method of conveying the fertilizing germs from the anthers of the staminate to the pointals of the pistillate blossoms. Among insects, it seems the honey-bee, in her floral wanderings in search of nectar and pollen, in consequence of her peculiar form and downy covering, should be entitled to a first place in the work of direct and cross-fertilization of fruit-producing flowers of all kinds; and were it not for this generous and disinterested aid to the chances of nature, the loss to fruit growers would be much greater every year from sterile bloom.

That the honey-bee causes injury by extracting the nectar from fruit-producing trees and shrubs, is simply fallacious, notwithstanding the generally entertained and oft-expressed opinion of those ignorant of dame nature's process of reproduction, to the contrary. During the past two following seasons I have observed apple trees loaded with well developed matured fruit in autumn, that bloomed several days earlier than the remainder of the orchard, and were swarming with bees until the bloom from the other trees shared their attention. Two of the trees alluded to, stand but a few feet from some of my hives, and have always been favorites with the bees during the season of bloom, but I have yet to note any diminution in their products caused by the bees sipping nectar from their blossoms.

The discussion of this subject, of "planting for honey," is receiving a merited attention from contributors to the BEE JOURNAL, but it appears to be too desultory to produce the benefit it might, if in a more concise form. Would not a more favorable influence be exercised by having a space in the bee publications in which those who have tested the qualities of honey-producing trees, shrubs and plants of various kinds, can be allowed to give their experience in detail. The names of trees, etc., and their adaptability to location in all sections of our land, from Maine to California, is needed. As the pursuit of the apiarist is constantly prompting his attention to the sources from which honey is obtained by his bees, who is more favorably situated to observe and reduce the results of his observations to utility?

Again, if properly appreciated, a triple benefit may be derived from the result of such a consolidation of effort; a more general cultivation of food-producing trees, shrubs and plants, a more bountiful return for apiarian enterprise, and the unequalled advantages of studying the illustrations of nature from her open book of floral beauty; for

"There are sermons in stones,
Music in the trees,
Books in running brooks,
And good in everything."

For the American Bee Journal.

Sundry Matters from Canada.

ALLEN PRINGLE.

I find, no matter how much one may know about the science of bee-keeping, or even of the art, through experience, the BEE JOURNAL is a great desideratum—a real aid to be desired and valued. The varied experience of different bee-keepers contributed to its columns, is interesting and valuable, no less to the professional than the amateur apiarist.

With one thing, however, I feel disposed to find a little fault, or rather kindly admonish those concerned, and in doing so, I hope to give no offence, as the admonition is given in no carping or captious spirit, but solely for our common good as bee-keepers. Some of the reports sent in seem, at least, *prima facie*, to be over-drawn or exaggerated. This, however, may be entirely unintentionally on the part of those who send such reports; nevertheless they are misleading, and tend to lead to evil consequences in more than one way.

When a correspondent says he has taken so many hundred pounds of honey—an almost fabulous amount—from a single colony of bees in the one season, he may be quite honest in his statement; but his statement may, at the same time, need much qualification or, at least, explanation, and this ought always to be given. A hive of bees may be large—much above the average—and it may have one story, on top of another, and it may be kept the whole season gathering honey instead of allowing it to swarm or dividing it; and under such circumstances, such a colony would, no doubt, during a good season, carry in an immense quantity of honey, comparatively speaking. But it would be either disingenuous to say that one colony of bees did all this, without giving any explanations.

By a colony of bees, the reader understands an average colony, under ordinary circumstances or conditions. Now, please bear in mind, I do wish to impeach the honesty or sincerity of a single correspondent.

So far as my experience and observation have gone, bee men, as a class, are proverbially honest and fair-minded men; and let us not, therefore, tarnish our fair name by making statements or reports which have even the semblance of fraud or misrepresentation. Let us avoid even the appearance of evil. Let us under-state, rather than over-state our exploits in our reports.

The amateur apiarist, starting out in the business with great and commendable enthusiasm, and, perhaps, superadded to that, great expectations of coining money, is only too apt, when he comes with honest pride to write his report, to draw upon the uttermost fraction for presentation. The temptation is strong to draw it at the highest instead of the lowest. But, gentlemen (and ladies too, for we have lady bee-keepers), let us be strictly, severely, honest and fair in

our reports, and in our statements of facts in our experience.

Sometimes incidents of apiarian experience are given, which seem to be in direct opposition to well-established principles or hypothesis, which have been well-nigh postulated into laws or principles.

I was present, last fall, in Toronto, at the meeting of the Ontario Bee-Keepers' Association the first night, and one gentleman stated on that occasion that one of his neighbors had buried the bees from a hive he had taken up in the fall in a hole in the earth, and duly filled it in, and in the spring, upon exhuming them, they were found to be alive and well—in good health. The gentleman improved upon this fact (?) by suggesting that the plan of wintering bees in a "dormant" condition, without any food, was well worth considering. This sage bee philosophy no one attempted to controvert; albeit Mr. D. A. Jones, our great Canadian bee-keeping, dryly remarked that he would not mind paying \$500 for a queen that would produce such unique progeny.

Experience, to be valuable, must be real. There must be no mistake about the facts. Then if they are facts, and are in conflict with certain preconceived theories, so much the worse for the theories. A few real, stubborn facts will sometimes spoil a very nice, plausible and time-honored theory. But before we discard the cherished theory, let us be sure that the opposing statements are facts.

It is, therefore, of the utmost importance, if the contributed experience of bee-keepers through the BEE JOURNAL, is to be really valuable in helping us forward to ultimate truth, that such experience should be most carefully and accurately stated, and nothing put forward as a fact if there is any uncertainty or doubt about it, especially if such alleged fact militate against a recognized principle.

Of course I am well aware that very unusual and even unheard of facts will sometimes arise in our experience, and this, on the other hand, should make us careful about putting anything down as an ultimate principle until it is well supported. The most unexpected things will sometimes turn up in the experience of the practical bee-keeper.

As relevant here, allow me to relate a little incident in my own experience: Last summer, in clipping the wings of a young, recently fertilized Italian queen, in a new colony, I accidentally cut off one of the legs of her royal highness. This was ungallant, but there was no *malice prepense*, as the lawyers say. Not knowing exactly what the upshot of this surgical misadventure might be, I kept an eye upon her majesty for a few days. I found, however, that she laid all right, only seeming to experience a little difficulty in locomotion, being a trifle awkward in her movements. She was very prolific, and things went on swimmingly in her establishment, although the head thereof was minus a leg and without wings. In a short time they began to prepare for swarming, by starting numerous

queen-cells, all of which I destroyed, or supposed I did; I examined them again in a week or ten days, but found no new cells, and was not aware that in a sly corner was one just about hatching, of the original ones which had escaped my notice. It so happened that I did not look into this hive again for two weeks or more, when, there I found a young, fertile laying queen, wings, legs and all. I looked around, and upon another frame found No. 1 minus foot and wings. There they were, both in the hive, and no mistake. I was a little puzzled; looked around and found the place where the cell had been, which had escaped me, when I was destroying the others. At first thought, I had supposed No. 2 had been but recently hatched, and that the two royal rivals had not yet met. But, no; the young queen was evidently fertile and laying, as I afterwards proved. To test matters, however, and look further into the problem, I closed the hive until the next day, when I examined it again. I still found both queens there on different frames. No. 1, with wings and leg off, seemed, however, to be neglected, and I noticed a slight diminution in the size of her abdomen.

My theory, whether right or wrong, was this: The workers, being cognizant of her deformity, were superseding her. They were nourishing the young and perfect queen, and neglecting the deformed one, and, hence, she had ceased laying. But this ungracious business did not happen to agree with my notions of entomological ethics, and I accordingly put a stop to it. Besides, barring the deformity of No. 1, she was a fine, handsome queen, and very prolific. I accordingly took out No. 2, clipped her wings, and put her in another place where she was needed, and left No. 1 to "hold the fort." The usurper being gone, and the bees finding that fact out, turned their attention to their rightful mother, and nourished her as she deserved. All went well, and she is now safely away with her colony in winter quarters, as also the other. Now, whatever may have been the experience of others in this direction, the fact of two fertile queens occupying the same hive together for some days, was, to me, something altogether unprecedented.

The winter here (Eastern Ontario) has, so far, been unusually severe, the temperature, frequently dipping much below zero, and we have had continuous sleighing nearly three months. As a consequence, some of the old-fashioned bee-keepers, in this section, who leave their bees out during all the winter on the summer stands, without any protection, will, I fear, as Mr. Jones says, be in "mourning" in the spring. Of course we have some few bee-keepers here in the East who try to keep up with the times and do the business scientifically; but there is, I believe, a larger proportion of such in Western Ontario, where Mr. D. A. Jones is located, and where his influence in developing apiculture has been much felt. In the past two or three years. Of course every Cana-

dian bee-keeper is proud of Mr. Jones, whom I had the pleasure of meeting for the first time in Toronto, last fall, at the Industrial Exhibition, where he had a splendid display of almost everything pertaining to the art of apiculture. I was very favorably impressed with the genuinely progressive and cosmopolitan spirit of Mr. Jones, who, though having made many inventions and improvements in apiarian apparatus, patents nothing, but leaves all free to make from his patterns. This admirable trait is as rare as it is generous. Without, evidently, having had many scholastic advantages, Mr. Jones has, by his native ability, genius and industry, placed himself in the very first rank of eminent apiarists, and has shown more enterprise in the business than any of his compeers.

In the eastern part of the Province here, we have recently lost one of our best and most enthusiastic bee-keepers. I refer to Hon. Lewis Wallbridge, of Belleville, who has lately been elevated to the chief justiceship of the new Province of Manitoba. Mr. Wallbridge was president, last year, of the Ontario Bee-Keepers' Association, and was a very enthusiastic amateur bee-keeper. I fear, however, that he will not be able to enjoy his favorite recreation in the Northwest, as the climate, I understand, is too severe for what he used to call his "little pets," the bees. If these "little pets" failed to let him feel their stings once in a while, he said he felt "neglected." Most people would prefer to suffer that kind of neglect, but not so with the redoubtable Lewis. In the East here we have another very good bee-keeper, Mr. Wm. C. Wells, of Thurlow, Hastings County. Mr. W. is quite a genius in his way, he makes nearly everything he wants in the bee line for himself, even to making foundation comb.

Lennox Co., Ont.

For the American Bee Journal.

Extracted Honey and Extracting.

FAYETTE LEE.

In my last article I described my plan for getting bees ready for the honey harvest, and that comes about July 6. Last year basswood bloomed on July 19. The bees need all the honey from dandelions to rear their brood. You may see the comb begin to look white, and in a few days it will be all capped over; but let it stand in the hive until June 25, then get the honey extractor ready and a sweet barrel, well waxed, to put the first honey in; this done, you need a good smoker, screw driver, and a turkey wing. Take the comb basket and stool to put the upper story on, and commence at hive No. 1, put the screw-driver between two frames and pry them apart, smoking the bees at the same time; put the upper story on the stool, take out four of the outside frames, put them in the comb basket, and fill up the brood-nest with frames of foundation. Put back the

upper story and take out every frame and extract them and return them to the hive. Now, we have four spare frames. Go to No. 2 and take off the top story, as before, take out four frames and put in the extra four, and put on the upper one again and extract the same as No. 1. We take out all the dark honey, so that it will not get mixed with the basswood honey. Do not stop to strain the honey. Put it in a 40 gallon barrel and let it stand a few days, when all the small cap-pings will be on the top. Then skim it and cover it with sheeting. By all means keep each kind of honey by itself.

My honey weighs 11½ pounds to the gallon. It is a disgrace to a bee-keeper to have honey sour. The cause of its souring, is that it was extracted before it was ripe. When it is capped, it is ripe, and the bees put their seal on it. If you want to spoil the sale of extracted honey, sell your store keepers unripe honey, and you will do it the first time. It is not the big yield we want, but good honey. We keep this first honey till September to feed, if we need it. My honey in June is dark in color, sometimes. Goldenrod does not give much honey, and we want this to feed the bees.

Having taken all the dark honey out on June 25, the next yield will be from the basswood. Wait about four days from the time the first basswood honey comes in, then open all of the top stories, and put the outside frames in towards the centre, and close up the hives. In this way I get all the frames full about the same time, so that I can extract it all at once. In about four days more, the bees will have it capped over. Now we are ready to take the first basswood honey. We will commence at No. 1, and extract four frames from the brood-nest, and all from the upper story. Be sure to take the outside frames in the brood-nest. I only extract two times during the basswood harvest. Now being through extracting for a while, put the honey in tin cans and glass jars for market, and label it "PURE HONEY," giving your name on every can and jar, that you have. I believe every bee-keeper has a right to set a price on his honey; if every one would do so, it would be much better for them.

I have been in the bee business for six years, and have sold 6,757 pounds of honey, and put my own price on it, and it averaged 11 cents a pound.

In producing extracted honey we have surplus combs to use from the last year, and bees will store honey when they will not make comb. One year I tried tiering up, with a few hives, and did not extract until the honey harvest was over. I found that the bees had not capped the honey, for they had too much surface room to cover, through August and September.

Do not extract from the brood-nest, but take all they put in the upper story. There may be better ways to manage bees to produce comb honey, but the way I have managed has given me 92 pounds of extracted honey to the colony, spring count. If

beginners will follow my way of swarming, they are sure to have strong colonies, and that is the sure way of getting a large crop of honey. Do your best, and the bees will do the rest, if there is any honey to gather. Cokato, Minn.

For the American Bee Journal.

The Use of Separators.

T. E. TURNER.

I confess to becoming "so insane" as not to use separators, and will not charge those who continue their use with insanity; but will confess that my experience has made me so sane as to discontinue their use. My experience with them has been varied. I have used narrow strips of tin for separators, and also broad pieces, and find that bees work best with narrow strip separators, if any are used; but they will build some combs fast to the tin. With broad pieces and large passages for bees to enter the sections, combs are built under, out of shape for casing, and with broad pieces and narrow passages, bees are slow to commence work in the sections. Some may force them into sections with such separators by keeping them in prime condition, but with all the forcing I can do, they are slow to enter sections with narrow spaced separators.

That separators lessen the crop of surplus is not a delusion, as is proven by the experience of many leading apiarists. To test this matter, last season, I put a frame of sections in each end of a hive, one with and the other without separators, and the bees worked in the one without separators, and would not touch the other; then they were changed in the hive, and new sections put in with the same result. Then sections were put in both ends of the hive without separators, and they worked in both places nearly alike. Now this result, with the fact that bees will, things being equal, work more readily in the space occupied by 8 or 9 sections than that occupied by one section, proves that as much honey cannot be obtained with as without separators.

Now, with the right kind of a rack to hold sections, and a little care in putting starters in, I claim that one can manipulate more colonies of bees for comb honey, without separators, than he can with them, and produce his honey in just as good shape for market. The reason for this is, that he will have to give less time and care while the sections are on the hive, to see that they get sealed, and taking them off, and no more in casing them for market.

The finest section honey in Chicago, at the time of the meeting of the Northwestern Convention, and, perhaps, during the past season, was produced by a bee-keeper in this county, without separators. Seven thousand pounds were produced from 60 colonies, spring count, in that way. Twenty thousand pounds of first-class honey was produced in this part of Wisconsin, last season, with-

out separators, and packed and shipped to various points with no complaint of leakage from combs rubbing each other.

Mr. Steer's narrow frame and separators, described on page 189 of the BEE JOURNAL, for April 11, though he uses a division-board, will not admit of the speedy removal of the full sections from the hive, and the bees will propolize his section frame to the hive, if it is the same size as the inside of the hive.

Glassing sections is too expensive both to producer and consumer; for the time and cost of glassing is much greater to the producer than he gets returns for, and the glass is useless to the consumer.

So separators are dispensable, and bee-keepers are dispensing with them, and also with broad frames, and are adopting suitable racks in their stead. Progressive apiarists here would not think of securing a large crop of comb honey in marketable shape with their use now.

You will see from these remarks that the articles on separators, tin or wood, that have appeared recently in the BEE JOURNAL, are of but little interest to some of its readers, for they regard them as useless and cumbersome.

Sussex, Wis.

Western Michigan Convention.

The Western Michigan Bee-Keepers' Association held their regular semi-annual meeting at Grand Rapids, Mich., May 3. There were about 20 members in attendance.

The meeting was called to order at 10 a. m., by the president, W. H. Walker, of Berlin. Secretary Franklin S. Covey, of Coopersville, read the minutes of the last meeting, and they were approved by the association. The treasurer's report was also read, which showed the society to be in a good financial condition. All expenses had been paid, and a surplus of a few dollars still remained in the treasury.

The forenoon was chiefly occupied with discussions on wintering bees. T. M. Cobb, of Grand Rapids, introduced the subject with a few remarks.

Quite a number spoke concerning the matter, and the general sentiment of the convention seemed to be that a good cellar was preferable to any method of out-door shelter.

A. B. Cheney, of Sparta Centre, had wintered his bees in a cellar for ten years past, with uniform success.

President Walker thought that they should be so protected, if left out during the winter, that they would not be compelled to rely upon the rays of the sun for their warmth—that heating apparatus was too variable.

Secretary Covey thought that too much pollen was detrimental to a healthy condition in bees. Honey taken by the bees passes off in insensible perspiration, having no ash in the bowels of the subjects, and they need not fly to void their faeces. Pollen is stronger food, and excites breeding in the winter time, when such an act is

out of season, thus causing disease and otherwise disarranging the system of the hive.

A. A. Dodge, of Coopersville, presented the next topic for discussion—the subject of foul brood. He had met with good success in using the Jones method of cure. He shakes the bees of their combs into a box which has been provided with thorough ventilation, and places it in a cool, dark place. The bees remain in their comparative dungeon for two or three days, in a state of absolute fasting. They are then removed to a new hive. He starves the bees until the infected honey of the sacs is all consumed. The use of automizers and salicylic acid had proved unsuccessful in meeting the desired end.

T. M. Cobb made a few remarks upon the different varieties of bees. He expressed a preference for the Cyprians. They were more hardy and better honey gatherers. They would breed faster, and raise more and better queen cells; also, they were less liable to swarm.

The meeting, upon the whole, abounded in features of interest. Although the attendance was not as large as the merits of the discussions deserved, yet those who visited the scene displayed the greatest zeal in their work of investigation, and retired at the adjournment of the meeting fully satisfied with the manner in which they had spent the day.

The fall session of the association will be held at Berlin, on the last Wednesday in October.—*Grand Rapids Times*.

For the American Bee Journal.

Essentials of a Standard Frame.

E. B. SOUTHWICK.

I notice that every little while there comes up the subject of the "standard frame," and an article giving the writers preference, but seldom the inherent properties, for which the preference is given.

It is also frequently asked, "What is the best frame?" And the answer given is, "We use the ——— frame," without giving the merits that frame is above all other frames. The two classes of frames that their advocates have been trying to have recognized as the standard frame, are, I believe, the long and shallow frame like the Langstroth, and the nearly square ones like the Gallup.

Now, I request that some one, fully competent and versed in all the wisdom and lore of the Langstroth frame, and its every property and merit, will write an article and mention every good feature it has, not leaving out a single quality that recommends it to be "the standard frame," and I will write an article comparing its merits with that of the square frame, and have both articles printed side by side in the same JOURNAL, and copied into other papers, if their editors can be induced to do so. Then when the kind of hive or frame is asked for, the inquirer can be referred to these articles for the reasons for either.

The advocates of the square frame may think their side is poorly represented, but do not mention that, lest the other side make that an excuse, and keep mum. If my proposition is agreed to, I will write out my article as soon as I know it, and know who the other advocate is to be.

Mendon, Mich., May 10, 1883.

For the American Bee Journal.

The Great Need of a Bee Boom.

JOS. M. HAMBAUGH.

This section is sadly in need of a bee boom. Old fogyism reigns supreme, and notwithstanding the surroundings, will warrant the belief of this being a superior point for harvesting the nectar, but few of my neighbors use a movable frame hive, preferring to indulge in the old-fashioned box, constructed of rough planks, with round sticks through the centre, and, perhaps, slats at the top and bottom. This seems, in their estimation, a broad stride over the old-fashioned mode of hollow bee logs, sawed up in about 3 feet blocks, with a roof over one end; not appearing to see the gist of the new-fangled idea of the movable frames; and though they keep abreast of the times in other matters, the poor little honey-bee is left to battle with the ignorance of the past.

The common German black bee is the only kind within 20 miles of this section, if I mistake not; and yet honey (though of an inferior quality) has always been abundant.

To the east and southeast of my residence is spread a vast waste of low lands, four miles in width, reaching to the Illinois river, which is subject to overflow. This region is studded with willow, button-brush, boneset, pond-lily, Spanish needle, and myriads of other blossoms, not known to the uncultured. To the north and west are the bluffs, whose fertile hills, where not disturbed with the woodman's axe, is heavily wood, with linden or basswood predominating. How many colonies can I have without exhausting the pasturage? I have 17 colonies with which to make a start; all natives, and I intend to Italianize as soon as all are in movable frame hives. I have 27 Langstroth hives completed for the purpose, and I wish to ask if the perforated zinc, for excluding drones and the queen from the upper story, is a success? If not, what device is used, if any?

The writer has had the pleasure of visiting Charles Dadant & Son, of Hamilton, Ill., and though we came as a stranger, we were treated as a brother. A glimpse among their bees and foundation manufactory was worth many times the expense of my trip, and opened my eyes to the onward march of scientific bee-culture. Long may they live as shining lights in scientific bee-culture.

Versailles, Ill., May 14, 1883.

[Your pasturage resources are good, but you will find the 17 quite enough to begin with. As they in-

crease, so will your knowledge of the business increase, by the practical knowledge you will obtain in managing them. The zinc excludes are used by many, and are considered indispensable by them.—ED.]

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Snndry Questions.

1. How long should the brood-comb remain in the hive before changing for new; as some claim that the cells gradually become less by frequent breeding in them?

2. How old ought a queen to be before she should be replaced with a young one?

3. Does the old queen leave the old hive with the first swarm in the spring?

4. Why do bees lie out on the sides of the hives, so long in spring, before they swarm; are they waiting for a queen to hatch, or is their old queen to come with them, and she is too old; or what? D. F. MARKS.

South Bosque, Texas, May 9, 1883.

ANSWER.—1. I never destroy a comb on account of its age alone. I saw comb that I was assured came from a hive over 40 years old, and the owner pronounced the colony as vigorous and prosperous as ever.

2. She ought not to be replaced as long as she proves worthy, by her works.

3. Yes.

4. There are two reasons for such laying out; first, the neglect to give them full opportunity to work, and sometimes intense heat, and when the master does not do his duty they swallow large drafts of honey and hang outside of the hives in clusters, transforming that honey into scales of wax.

Is it Square-Dealing?

In looking over a bee paper (not the BEE JOURNAL), I saw the following: "Square dealing men." We, whose names appear below, do not know that we have a single dissatisfied person with whom we have had dealings; but if we have, such will confer favor by writing us kindly, and we will do our best to render satisfaction.—Among those names, is one with whom I have had a little "deal," and I fear that little was, at the best, "a deal too much." I will put the case by asking some questions which I wish answered through the BEE JOURNAL, as I have twice written the party and can get no reply from him.

1. Is it square-dealing to advertise a Langstroth frame, and send a Sim-

ply? 2. Is it square-dealing to sell colonies of bees that have had or been exposed to foul brood?

3. Would bees that were healthy and free from the disease in May, be likely to die of it in the fall?

4. If you should take frames of brood and bees from a hive and form a nucleus in June, and the old colony dies in the fall, and next fall you find that colony (the nucleus) has the foul brood, would you not think it came from the frames forming that nuclei, especially if those frames contained most of the foul brood?

5. If there were no bees within $4\frac{1}{2}$ or 5 miles, domestic or wild, would there be any probability of their becoming infected from outside, or wild bees, and dying the same season?

6. Is there any redress for one who is thus imposed upon, unless through exposure, which most or all dislike to do, but right should supplant right and wrong. O. B. SCOFIELD.

York, Maine.

ANSWERS.—When I first saw that "square" department, I thought that it would only serve as a hiding place for some dishonest dealers to lurk in, where they could deceive many beginners of our pursuit. In it I found the names of men of whom I had heard grave complaints, and failed to find the names of some of our well-known reliable dealers. It reminded me of the French bastille, prior to the Revolution, where "most that were in, ought to be out, and many that were out, ought to be in." Right here I want to express a long harbored opinion, and that is, that he who succeeds in giving perfect satisfaction to all he deals with, will do great injustice to some of his customers or to himself. It is not right, and is an immoral method of seeking patronage to indulge the selfish in their unjust demands. Some just person must foot this indulgence bill. Besides this, it develops to a higher degree this wrong propensity in the indulged. Each dealer should draw his own line of justice, and in drawing that line, use his imagination with which to place himself in the outside party's place, and then live up to this, his highest conception of justice, and let the people decide by their acts whether or not he has drawn the line well. No man who does this duty, can honestly get into that "square-list" upon the terms it proposes. No man can deal with one hundred customers exactly on the square, and nothing more, and not have one dissatisfied. My advice is, do not try it. "Dare to do right; dare to be true," and you have nothing to fear.

I have dealt in supplies on quite an extensive scale for three or four years,

as many well-know, and I have three very much dissatisfied customers, and I wish it was not out of place to give a history of the origin of their dissatisfaction; also of their Christian spirit in reporting the same, together with the direful things they are going to do, but never commence. It is also true that some dealers have not aimed to do justice, and under this head I will try to answer the questions, as best I can.

1. The Langstroth and Simplicity frames are calculated by their makers, to be one and the same frame. The words Langstroth and Simplicity apply to the styles of the hives, and not the frames.

2. No, sir.

3. Bees do not die of foul brood. It is a disease of the brood, and the colony would "peter out" in the fall if the disease was well under way, and of a malignant type in the previous spring. This is as I understand it; though I have never seen a case of foul brood.

4. I should.

5. Very little, if any, I should say.

6. I am not a lawyer, but as laws are based upon reason and justice, I would guess that damages could be collected in a civil court, if the parties were collectable. The distance the parties are usually a part, and the financial worthlessness of many small dealers, makes the legal course usually impracticable. The exposure course is in order, but there is no place, except in apicultural periodicals, through which to do it, and the nature of the complaint and defense are incompatible with the purposes for which said papers are published and read.

Wired Frames.

1. Will bees build comb in wired frames and have the wires in the centre of the combs?

2. Will they do it readily.

E. SANFORD.

ANSWERS.—Yes; if you properly press the wire into the foundation. If you do not mean to use foundation, do not use wire at all; it will not work on that plan.

2. Nearly all now know the advantages of the wires when used with foundation, and I have used them for years, and find them in no way detrimental. The Given press puts them to place more perfectly and quickly, but the hand method is excellent, and perfectly practical when done as I described it in the February number of the *Kansas Bee-Keeper*. I advise all

not to buy frames filled with foundation, but wire their own frames and put the heavy foundation on by the method above referred to; it is safer and cheaper.

SELECTIONS FROM OUR LETTER BOX

Shipped His Bees.

I left Delta, Ohio, for this place on April 20, with 43 colonies of bees, and arrived here without the loss of a comb.

MILES S. PRAY.

St. Johns, Mich., May 10, 1883.

Looking for a Grand Honey Harvest.

My bees have done well so far, and are in fine condition. I have had one swarm on May 2. Prospect are booming for white clover, and we are looking for a grand honey harvest.

J. G. NORTON.

Macomb, Ill., May 14, 1883.

Moving Bees in Cold Weather.

My 9 colonies of bees came through the winter all right. I bought 40 colonies more, which makes me 49 to commence with. Those which I wintered came through very strong. They had drones dying on the 10th of May. The 40 which I bought are not so strong, covering from 6 to 9 of my frames, which are 10 $\frac{1}{2}$ x 12 $\frac{1}{2}$ inches, outside measure. A neighbor of mine bought 8 colonies of bees in what is termed the "patent" hive; he put them into a cave last fall. They were doing very well in the cave. Mr. M. told him that his bees would all be dead before spring, if he did not take them out of there; so he took them out and hauled them on a sled one-quarter of a mile, in the coldest part of winter, to an old house, and there buried them up with oats, as if they were ice. Long before spring, his bees were dead, and now he has only the old boxes and combs (for some one stole the honey) for the \$20. The fruit trees are in bloom, and we expect a full crop of honey.

J. F. SELLERS.

Reynolds, Ill., May 12, 1883.

Apiary Destroyed by a Tornado.

May 9, about 5 p. m., this section was visited by a terrible tornado, which laid my apiary in ruins. I had 40 good colonies, and not a hive escaped the fury. They were carried up in the air, through the woods, and the hives smashed into "kindling-wood," combs and frames carried over a mile and dashed to atoms, and the bees drowned. You can imagine my feelings, for there is nothing I think so much of as my bees (except my family). I was just starting an apiary anew, after my disaster in Iowa. This was my first season here, and my apiary is my only dependence. I have 17 queens left, that I picked up, and bees enough for 5 or 6 colonies;

the unhatched brood was nearly all chilled in the combs I saved, so it is dead and the bees are dragging it out. The tornado also damaged my house, twisted it out of shape some, and took about 20 feet off one of the side walls out of my bee cellar, so I had to get help and prop up the house, to keep it from falling over. The house is a frame one, just built, last October. I think the elements have been hard on me, but it might have been worse as none of my family were killed or hurt.

E. J. SCOFIELD.

Hanover, Wis., May 12, 1883.

Parasitic Bees.

Enclosed I send a specimen of a fly, which I discovered among my bees. Please describe and explain through the *BEE JOURNAL* what they are. They seem very lively among the bees. I think they destroy eggs, and do mischief.

GEO. D. FRESHOUR.

Canandaigua, N. Y.

[The insects are parasitic bees. Three specimens were received, of which one belonged to a distinct species from the other two. I should be glad to get more of each. These cuckoo-bees have not been known to infest the cells of the honey-bee, so far as I am informed, but are well-known predators upon various wild bees. Their eggs are laid in the cells, and the strange larvæ are fed like those belonging to the host. It is not at all probable that these adult bees destroy the eggs already laid by the hive queen; though careful observation on this point would be valuable.—T. J. BURRILL, Champaign, Ill.]

Bee-Keeping in Florida.

I have spent the past winter in Florida, and will hazard the opinion that bee-keeping in that State will not be a success to any great extent, except in a very few localities where there is a plenty of mangrove, palmetto, etc. A few bees could probably be kept in almost any locality.

Bonair, Iowa. G. W. WEBSTER.

Bees Prospering.

My bees came through the winter with very little loss, and are now doing well, notwithstanding the cold and backward spring.

G. W. ZIMMERMAN.

Napoleon, O., May 15, 1883.

That Apiarian College.

I noticed an article on page 6 of the present volume of this *JOURNAL*, entitled "Another step in advance." The writer, Dr. Besse, says that it would be advisable to start an apiarian college under the auspices of the American Bee-Keepers' Society; each graduate to pass an examination before that society. I would like to ask the Doctor or Mr. Heddon to suggest a number of the leading questions for a person just starting to keep bees to ask himself, and be able to

answer, so that he may be thoroughly acquainted with the science of bee-culture. Mr. Heddon says in an article on page 73, that the art is acquired by the majority. Of course it is, but I think it would be a great deal easier to acquire the art after or when a person is studying the science with the art. A very large number start to keep bees every year, and I might say that a large number of them never get past the first year or two, unless they just swarm them in boxes, and let them have their own way. I think a great deal of good could be done if some one that is more able than myself would take up the subject and do it justice. WM. H. WESTON.

London, Ont.

Cannot be Beat.

I think the BEE JOURNAL cannot be beat. I would not lose a number for the price of it a year.

F. M. TAINTOR.

Elm Grove, Mass., May 15, 1883.

Bees Wintered Without Loss.

My 35 colonies of bees were packed, last fall, by putting chaff cushions in the caps, and they wintered all safely; I did not even lose a queen. They are now doing well, and there is a good prospect ahead. My experience teaches me to keep a laying queen in the hive, if possible, all the time, Mr. Heddon to the contrary, notwithstanding.

ISAAC SHARP.

Waveland, Ind., May 16, 1883.

Spring Management, etc.

I have a few questions which I would like to have answered in the next number of the BEE JOURNAL. They are of great importance to bee-keepers at this time of year, especially those that have several hundred combs and but very few bees; which is the case here with several. One man at Mecosta, Mich., put in the cellar 54 heavy natural swarms in the fall; on the first of May he had only 10 weak ones left; another at Coral, Mich., packed 38 natural swarms in straw; he has only 7 weak ones left. These men want to know how to build up these little handfuls of bees, so as to make use of these combs.

1. Is it any advantage to feed this honey back to them, the combs can be placed in the caps of the hives, so that the bees can have access to them very easily, and those on the outside be none the wiser, and will take all of the honey out of the combs and clean the combs up some too; but is it any gain? Will the bees breed any faster for having plenty of honey in the hive?

2. For all of the advertising of queens, none can be found for sale at present; although all queen breeders are willing to receive your orders for queens, which will be filled in the order received, sometime in June or July. How early can queens be reared in this latitude? How soon should queen-rearing be commenced, when there is such a demand for them? Cannot queens be reared successfully at any time, when drones are plentiful? I have drones in any quantity at this date.

3. What do the experienced apiarist think of Alley's new method of queen-breeding? I have a colony engaged in the business already. I think it will be a grand success.

S. J. YOUNGMAN.

Cato, Mich., May 15, 1883.

[1. In the excellent article on page 260, by Mr. Doolittle, will be found instructions for spring management, building up weak colonies, etc.

2. It is too early in this latitude to think of shipping queens, even if they were ready for shipment. The nights are cold; and the exposure they would get would be detrimental.

3. As you are rearing queens according to the plan given in Mr. Alley's book, of course there is no necessity of further answers in detail. We refer you to the book, which meets with very general approval by apiarist everywhere.—Ed.]

Splendid Honey Harvest Expected.

My colonies are in splendid condition: full of brood, and strong in bees. The locusts are just opening, and the surplus arrangements are placed on; the hives have a surplus of fruit bloom honey; the first of the kind in three years (that is, surplus above what they needed for rearing brood). It is fine weather now, but we had cool weather up to last week; some days it has been too cold for bees to fly. We hope, and have the indications of a splendid honey harvest; white clover looks well, and basswood trees are full of buds.

J. W. STURWOLD.

Haymond, Ind., May 18, 1883.

Troubles in Transferring.

I had 2 colonies in box hives; I transferred them, last week, into movable frame hives, according to your instructions, and succeeded beyond my expectations, without any bee-vail, and received no stings, but I do not understand the way they acted. The first hive was very strong; a peck of bees, at least, and five queen-cells, and one was capped over, and two others with larvae in them. I put eight frames in the hive with most all the brood, and very little honey. I placed the new hive on the old stand, in the same place, and dumped the bees in front of the hive, which were about a peck in bulk; part of them went into the hive, and some of them raised in the air and clustered about 30 yards from the hive. There was about a quart of them. I hived them at once; went into dinner, and when I came out they were clustered in one corner of the hive; in about half an hour they were gone, perhaps to the old hive. They would not go in the hive, so I raised the hive in front and they went into the chambers outside of the division-board, and staid there until I took them out. The next colony I transferred acted much like the first; it had about a half-peck of bees; they

had no queen-cells, but some brood. I emptied them in front of the hive; they did not go in the hive very good; some of them crawled over to the other hive, which was about a foot away, and clustered on the hive in large bunches. I brushed them down in front of the hive, but they would not go in. I left them there all night, still they would not go in; so the next day I took the cover of the hive, placed the boxes over the chambers and drummed and smoked them up and dumped in front of the other hive, which, by the way, had but few bees in it, so they went into the hive (at least some of them did) and staid in. I do not understand why they acted so. To-day, which is about a week since I transferred them, the strong colony gave a swarm. I hived it in good time; in ten minutes they were back to the same hive they came from.

C. VANCULIN.

Delaware, Del.

A Degenerated Langstroth Hive.

MR. EDITOR:—Will you please to give me your reasons for calling the Simplicity hive a "degenerated Langstroth hive?" I am only a beginner in the art of bee-culture. I want to learn all I can, and do not like to start with the wrong hive. I read your JOURNAL with great interest, and could not do without it. Please answer through the BEE JOURNAL.

O. H. CARPENTER.

Camanche, Iowa, May 17, 1883.

[Our correspondent has evidently been *dreaming*. The Simplicity hive is to all intents and purposes a Langstroth hive. It uses the Langstroth frame, and only gets its name by the manner of making the outer box. We have never used any such language, either in the BEE JOURNAL or in public speaking. Our correspondent should have designated the place in the JOURNAL where it might be found, or given the time and place, if we were reported to have used such a phrase in public speaking. We suspect that Mr. Carpenter has been *dreaming*, and this time is "caught napping."—Ed.]

How the Bees were Prepared for Winter.

We packed 5 colonies of bees in chaff and 5 with planer shavings, 4 inches in the bottom and sides, and 10 inch chaff cushions, on A. I. Root's plan. On October 27, the snow drifted over them; we shoveled them out in February, during a thaw, and some of the bees flew out. We examined them and found them all right. In April, we found some wet in the bottom of the hive; the cushions were moldy on top, but the bottom was dry and warm, and 4 showed signs of dysentery. We cleaned the hive of dead bees, but we lost 4 colonies, and 4 more are weak. At this date they have brood. I think if we had put them up out of the snow, they would have been dry; the snow is so heavy

here, with a damp atmosphere, it will not do to let them be covered up in snow as they do in the west. We put 38 colonies in the cellar on November 15, and took them out May 3. They were confined 169 days; 4 were dead; 2 of them starved with plenty of honey on the outside combs, the mat laid close down on the frames. I did not cut holes in the combs; 2 had dysentery, and several showed signs of it. Some of them were stronger when they came out, than when they went in. Others were weak; all had plenty of honey. Since putting them out, 2 more have died, and we doubled up two more; most of them had brood, and some had frames, capped over. They are bringing in pollen, but it is very cold and windy. Our cellar is under the house we live in; the thermometer stood at 36- to 40-; the hives were put up over the potatoes; some of them were as bright as they were last fall. We think that the cellar was too cold. We put a small stove in, to dry out the moisture. We had a pipe under ground to let in air, some 60 feet from the house, below the frost. The bees were in Root's Simplicity hives, with the bottom board up-side-down, with half-inch opening; burlap mat to cover the frames; cover up-side down. The bees in the cellars came out strong and better than last year. The bees that were wintered out on the summer stands in summer hives are all dead. JAS. H. TILLEY & BROS.

Castle Hill, Me., May 14, 1883.

Will they Bear a Queen?

I have a light colony that became queenless a week ago; I shall unite it to another.

1. If I give the queenless colony brood with eggs and larvæ, or if they have it already, will they rear a queen before drones have appeared?

2. If I give them a frame of brood with eggs, larvæ, and filled drone comb, will they rear a queen?

3. Will a colony rear a queen when its own hive contains neither drones nor drone comb, but when drones are in other colonies near?

4. In forming a nucleus, is it necessary to place drone combs in the nucleus hive? CHAS. F. WILLCOTT.

Exira, Iowa, May 5, 1883.

[If you have no prospect for getting a queen soon, it will be better to unite the queenless colony with any other weak one having a queen.

1. Drones will be on hand by the time the bees have reared a queen. Many have them now.

2. Of course they will immediately rear a queen, if you give them the means of doing so.

3. Yes.

4. No.—ED.]

All Old Bees.

I have been testing late and early breeding. My bees are all 8 months old; they bred none after August, last year, and very few young bees

have taken the field yet, which is 8 months and 10 days; therefore I will not be very uneasy after this if I do not get any breeding in September. My Italians will be ready for the honey flow, if we get fair weather. They are not so nervous as blacks, and pull through bad weather better. I have tested the two distinct races pretty well, and can give their pedigree any time. I kept a standing offer, last year, of \$5 for any person being attacked with an Italian bee; if it had been in favor of the blacks, I should soon have been in poverty. To explain the above, we got no fall crop here, and the way I fed up was on 6 frames; there was no breeding; neither could be. I was afraid, but apparently without cause.

CHARLES MITCHELL.

Molesworth, Ont., May 12, 1883.

Backward Spring in Maine.

Four inches of snow fell here today. It has been one of the most backward springs that we have had for a long time. My bees are quite weak, owing to the cold backward spring. G. W. DUNBAR.

North Anson, Me., May 15, 1883.

The Marshall County Bee-Keepers' Association meets at Marshalltown, Iowa, Saturday, May 26, at 10.30 A. M. The place of meeting is at the Sheriff's office. Subject for discussion: "Summer Care." The meeting of March 24th was one of much interest. Five new members were admitted into the Society. All present seemed to realize it was "good to be there," and the general feeling was to build up a good first-class society.

J. SANDERS, Sec.

BOOK CLUBBING LIST.

We will supply the *American Bee Journal* one year, and any of the following Books, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

	Price of both. Club
The Weekly Bee Journal,.....	\$2 00..
and Cook's Manual, 7th edition (in cloth) 3 25..	2 75
Cook's Manual, (in paper covers).....	3 00.. 2 50
Bees and Honey (T. G. Newman) (cloth) 2 75..	2 50
Bees and Honey (paper covers).....	2 50.. 2 25
Binder for Weekly Bee Journal,.....	2 75.. 2 50
Apiary Register for 100 colonies.....	3 50.. 3 00
Apiary Register for 200 colonies.....	4 00.. 3 50
Dzierzon's New Bee Book (cloth).....	4 00.. 3 50
Dzierzon's New Book (paper covers) 3 50..	3 00
Quinby's New Bee-Keeping.....	3 50.. 3 25
Langstroth's Standard Work.....	4 00 3 75
Root's A B C of Bee Culture (cloth) 3 25..	3 00
Alley's Queen Rearing.....	3 25.. 3 00
Scribner's Lumber and Log Book.....	2 35.. 2 25
Fisher's Grain Tables.....	2 40.. 2 25
Moore's Universal Assistant.....	4 50.. 4 25
Honey as Food & Medicine, 50 Copies 4 00..	3 75
Honey as Food & Medicine, 100 Copies 6 00..	5 50
Blessed Bees.....	2 75.. 2 50
King's Text Book.....	3 00.. 2 75

The *Monthly Bee Journal* and any of the above, \$1 less than the figures in the last column.

Renewals may be made at any time; but all papers are stopped at the expiration of the time paid for, unless requested to be continued.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Our stock of back numbers of this volume are now getting very low. Please look over your numbers, and if any are lacking, send us a postal card, giving the date of those you want, and we will send them, if not all gone. We give this notice, because, last year, several left it until the end of the year, and then requested us to send the missing numbers. Then it was too late, the numbers being all gone. Look them over now, and you may get them completed.

Foul Brood Pamphlet.—Wishing to be relieved of sending out my pamphlet on Foul Brood, I have made arrangements with Mr. T. G. Newman to supply them to the bee-keeping fraternity desiring them.

A. R. KOHNKE.
Youngstown, O., April 25, 1883.

Mr. Alley's new book on Queen Rearing will hereafter cost \$1.25

We have a few copies of our pamphlet entitled "Bee Culture" left, and have reduced the price from 40 to 25 cents each, or \$2 per dozen.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Will Make it an Even Dozen.—Mr. W. H. Brearley, of the Detroit (Mich.) Evening News, who has personally conducted \$22,000 round trip excursions "from Detroit to the Sea," every year for the past seven years, and who is to take three more this year in June and July, has made the ascension of Mt. Washington nine times, and, this year, proposes to make it an even dozen.—*Ad.*

Bingham Smoker Corner.

Large Smokers need wide shields. Bingham's have them, and springs that do not rust and break, and bellows that sparks and smoke do not enter. The Conqueror has all improvements made to date, and a 3x7 inch stove, and 5x7 inch bellows. Sent post-paid for \$1.75. Address,

BINGHAM & HETHERINGTON,
Abronia, Mich.

All Excelling. — Messrs. Bingham & Hetherington, Dear Sirs:—I am now selling your Smokers almost exclusively. You are excelling yourselves in smokers all the time.

Respectfully, J. G. TAYLOR.
Austin, Texas, May 10, 1883.

Cyprians Conquered.

All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am "boss." Bingham's "Conqueror Smoker" did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham.

G. M. DOOLITTLE.
Borodino, N. Y., Aug. 15, 1883.

Special Notice.—We will, hereafter, supply the Weekly BEE JOURNAL for one year, and the seventh edition of Prof. Cook's Manual of the Apiary, bound in fine cloth, for \$2.75, or the Monthly Bee Journal, and the Manual in cloth for \$1.75. As this offer will soon be withdrawn, those who desire it should send for the book at once.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

May we ask you, dear reader, to speak a good word for the BEE JOURNAL to neighbors who keep bees, and send on at least one new subscription with your own? Our premium, "Bees and Honey," in cloth, for one new subscriber to the Weekly, or two for the Monthly, besides your own subscription to either edition, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

E. T. LEWIS & CO., Toledo, Ohio,

Manufacturers of the U. S. STANDARD Honey Extractor (new improvements), and all other Apian Supplies. Send for circular. 17A 5Btf

PATENT FOUNDATION MILLS 6-inch, \$10.00,
10-inch, \$15.00.
W. C. PELHAM, Maysville, Ky.

THE HANDY BOOK.

Read the opinion of one of the most eminent writers on bee matters:

Round Brook, N. J., May 4, 1883.
FRIEND ALLEY.—Handy Book received. I am happy to say that I consider that it tells more on the vital subjects of rearing Queens and managing bees so as to take honey, than any book now before the public. It seems to be filled with just those things which practical men find out about their business in a lifetime of work, but which they generally don't tell the dear public.

J. HASBROUCK.
The HANDY BOOK has received from those most competent to judge of its value, more praise than any book now in print. Send for our Circular and get their opinions.

HENRY ALLEY, Wenham, Mass.
21Atf

A NEW BEE BOOK!

BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS C. NEWMAN,

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most honey in its best and most attractive condition.

Appreciative Notices.

A neat and abundantly illustrated hand-book of apiculture.—American Agriculturist, N. Y.

Its chapter on marketing honey is worth many times its cost.—Citizen, Pulaski, Tenn.

Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of every beginner with bees.—News, Keithsburg, Ill.

Valuable for all who are interested in the care and management of bees.—Dem., Allegan, Mich.

Engravings are fine. Gotten up in the best style, and is cheap at the price.—Farmer, Cleveland, O.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—Farmer, Lancaster, Pa.

PRICE—Bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

THOMAS C. NEWMAN,

925 W. Madison St., Chicago, Ill.

OPIUM Morphine Habit Cured in 10 to 20 days. No pay until cured.
J. L. Stephens, M. D., Lebanon, O.
18A4t

W. Z. HUTCHINSON,
Rogersville, Genesee County, Mich.,

is now receiving Italian Queens from the South (for particulars see advertisement in the BEE JOURNAL of April 18), and can send them by return mail at the following prices: Before June 1st, untested queens will be \$1.50 each; during June 1st, single queen \$1.25, or six for \$5.00; during July 1st, single queen \$1.00, six for \$3.50; during the home apertures, before June 1st, \$3.00 each; during June, \$2.50 each; after July 1st, \$2.00 each. Safe arrival guaranteed. Make money orders payable at Flint, Mich. 17cwt f

THE AMERICAN
BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

The New National Chemist.

Prof. H. W. Wiley, of Purdue University, has resigned the chair of chemistry there, to accept the position of chemist in the National Agricultural Bureau at Washington. Prof. Collyer was removed by Commissioner Loring, in order, it is alleged, that a more intense sorghum sugar man might be placed in charge of the chemical laboratory. So says an exchange.

He must remember that there are other equally important interests requiring the attention of the National Chemist, and give these due credit, as well as that of sorghum-sugar!

This Wiley is the one who invented the "paraffine comb and glucose" story, as a "scientific pleasantry," and, with it, deceived Gov. Porter, of Indiana, who, in his addresses before the Farmers' Institutes held at Columbus and Crawfordsville, reiterated the fraudulent fabrication, supposing, of course, that he was backed up by some authority, instead of being deceived by a *wily*, cunning and crafty un-scientific joker, the sound of whose very name is a suggestion.

Webster thus defines the word "wily:" "Full of wiles, tricks, or stratagems; using craft or stratagem to accomplish a purpose; mischievously artful; subtle; as, a *wily* adversary." There was no need of adding an "e" to that word!

Any one who could invent the lie about "paraffine comb" being made and "filled with glucose by appropriate machinery," and most likely laugh in his sleeve at those, who, being

deceived by it, were telling it as a sober fact, and then enjoy the *joke* for months, without doing the least thing to undeceive his dupes, is unworthy the name of man—for he lacks both manhood and integrity! Yet this is he who is now National Chemist, in charge of the National Chemical Laboratory, and what for? An exchange says it is because he is a "more intense sorghum-sugar man" than his predecessor.

Is he so "intense" that he must distort facts, manufacture a story, and publish a *lie* about honey, in order to serve his sorghum-sugar interest? Is this the key to his bold attack on comb honey?

Is he *such* an "intense sorghum-sugar man" that it becomes necessary to calumniate, by false reports, that God-given and pure sweet-honey—in order to make him the National Chemist? If that is the measure of his "intense" ambition—Heaven pity his poor contracted soul! It matters not what station such an one may occupy, all honorable men will unite in execrating him.

"Go! mark him well!
For him no minstrel rapture swell;
High though his titles—proud his name—
Boundless his wealth, as wish might claim—
Despite those titles, power, and pelf!
The wretch, concentered all in self.
Living, shall forfeit fair renown;
And, doubly-dying, shall go down
To the vile dust from whence he sprang—
Unwept, unhonored, and unsung!"

The Senses of Bees.

Sir John Lubbock, whose very interesting book we noticed in the BEE JOURNAL last fall, has recently read to the members of the Linnean Society an account of his further observations on the habits of insects made during the past year. The two queen bees which have lived with him since 1874, and which are now, therefore, no less than 8 years old, are still alive and laid eggs last summer as usual. His oldest workers are seven years old. The

American Naturalist for April has the following particulars:

Dr. Muller, in a recent review, had courteously criticised his experiments on the color-sense of the bees; but Sir John Lubbock pointed out that he had anticipated the objections suggested by Dr. Muller, and had guarded against the supposed source of error. The difference was, moreover, not one of principle, nor does Dr. Muller question the main conclusions arrived at, or doubt the preference of bees for blue, which, indeed, is strongly indicated by his own observations on flowers.

Sir John also recorded some further experiments with reference to the power of hearing. Some bees were trained to come to honey which was placed on a musical box on the lawn close to the window. The musical box was kept going for several hours a day for a fortnight. It was then brought into the house and placed out of sight, but at the open window, and only about 7 yards from where it had been before. The bees, however, did not find the honey, though when it was once shown them they came to it readily enough. Other experiments with a microphone were without results.

Every one knows that bees when swarming are popularly, and have been ever since the time of Aristotle, supposed to be influenced by clanging kettles, etc. Experienced apiarists are now disposed to doubt whether the noise has really an effect; but Sir John suggests that even if it has (with reference to which he expressed no opinion), it is possible that what the bees hear are not the loud, low sounds, but the overtones at the verge of or beyond our range of hearing.

As regards the industry of wasps, he timed a bee and wasp, for each of which he provided a store of honey, and he found the wasp began earlier in the morning (at 4 a. m.), and worked on later in the day. He did not, however, quote this as proving greater industry on the part of the wasp, as it might be that they are less sensitive to cold. Moreover, though the bee's proboscis is admirably adapted to extract honey from tubular flowers, when the honey is exposed, as in this case, the wasp appears able to swallow it more rapidly. This particular wasp began work at four in the morning, and went on without any rest or intermission till a quarter to eight in the evening, during which time she paid Sir John 116 visits.

Putting on the Sections.

Among beginners and amateurs the inquiry is often heard, "When shall we put the sections on our hives?" Mr. Dougherty answers this question as follows in the *Indiana Farmer*:

There can be no fixed time for putting on the surplus box, only as the season develops itself showing a surplus of honey coming in, and the necessity of giving room for its storage. The bees will seldom commence in the sections so long as there is any available space in the brood chamber in which to put the honey, and where the combs are not well filled with brood, the better plan is to occupy the extra space with a division-board, increasing the brood space as the queen becomes cramped for room in which to lay. Usually the first indications that the bees are gathering a surplus of honey, is the filling of the combs next to the top-bars of the frames, lengthening out the cells, showing the white, new comb which they are adding to fill in all of the unnecessary space.

Bees seldom get a surplus of honey before the coming of white clover, although where locust is abundant they sometimes get quite a surplus from this source. Too much room should not be given at first, as too much space at first may lower the temperature to such an extent as to retard brood-rearing. The better plan is to give but little room at first. After they have commenced in this nicely, then give more room, as required. They are at times loth to commence work in the boxes, and where a colony shows a hesitancy in occupying the boxes, some inducement should be given them; such as a section well filled with comb. We usually have a great many sections left over from one season to another, with which to encourage them, but have had to resort to the plan of cutting out a small piece of board and fastening it into the center section. We seldom bother with anything of that kind now, for where we find a colony that does not enter the sections at once, we lift them off, and hang on a full set of empty combs for extracting. After they have got well started to going above, they will most generally enter the boxes at once on there being replaced.

Apis Dorsata Coming.—Mr. A. Schroeder, one of our subscribers in Trieste, Austria, under date of May 2, 1883, writes as follows: "Mr. G. Dathe, of Germany, has arrived in Joppa with 4 colonies of *Apis-Dorsata*. He is very much disappointed in the fact that those bees will not build combs, neither will they stay on them. One colony decamped, and he was obliged to cut the queen's wings. I hope he will reach Europe with his bees alive, to have them to experiment with for the sake of science. I do not

believe the bees are worth anything for bee-keepers. Bees are doing well here. Strong colonies wintered well, and are in swarming condition now, if the weather would permit. I will build up nuclei into strong colonies, etc. We have never very cold winters here."

Seasonable Hints.

Mrs. L. Harrison gives the following directions in the *Prairie Farmer* for the management of bees at the present season:

Eggs and young larvæ disappear very mysteriously at times when there is a cessation in the flow of honey, and also when there are too few bees to hover and nourish it. A few days ago we gave a weak colony a frame of comb containing eggs, larvæ, and hatching bees. On examining them a few days afterward we found sealed brood, and young downy bees crawling around, but the cells were empty where the eggs and larvæ had been. The bees had been playing cannibal, breakfasted on the eggs and dined on the young larvæ. They had plenty of stores, but were lacking in bees necessary to produce warmth and nurses for the young, and so utilized them by devouring them. If chipping brood is given to weak colonies first, and as soon as it is hatched, eggs and larvæ are put in, there will then be bees of the right age to nurse and care for it.

Great care should be taken lest we injure our bees more than we do them good by meddling with them. If brood is taken from strong colonies, reducing them to the condition of the weak ones, great harm is done, for the brood given to the weak colonies may be entirely wasted. When the warm weather has come to stay, we may take brood with impunity, and not before. In the interim we must take care that the weak have plenty of honey in their hives, and feed the strong whenever they will accept it.

Bees are now carrying a great deal of water, and venture out for it when the mornings are quite cool. It will save the life of many a bee if drinking vessels are filled with warm water. We have some small kegs in the apiary which are filled with water, and some old muslin is put into them with a portion hanging over the sides, serving the purpose of syphons, and the bees suck the water from the muslin on the sunny sides of the kegs without danger of drowning.

We notice that quite a number of local papers have copied our article on "Bees and Honey in Ancient Times" from No. 19 of the *BEE JOURNAL*. It will help to educate the masses on the uses of honey, and if there are any more persons who think they can prevail upon local editors to get it inserted, we can send

them extra copies free for that purpose. Just send a postal card for No. 19, and it will be sent at once. Be sure to give your name and address.

Chickens Eating Drones.

Mr. Dadant, says the *Prairie Farmer*, "once had an apiary located on the side of a hill and fenced. He also had, at the same time, 500 chickens occupying the some enclosure with the bees. He had his hives raised from the ground, and at night the hens brooded their chickens under them. He also taught his chickens to eat drones, by feeding them brood and hatching drones. He says he has seen a rooster pick them off as they were clustered closely together for mutual protection against their female prosecutors, as all bee-keepers have seen them do, until he could swallow no more, then rest a bit, stretch up his neck, and go for them again—and if corn was thrown to him he would not notice it."

The weather for the past few days, in the whole Northern States, has been cold, windy and wet; but with a warm sunshine added to the well-watered ground, the flow of nectar will be abundant. It is true that the colonies of bees have become weaker, and in some cases "spring dwindling" has been severely felt, but, on the whole, an abundant honey harvest is to be expected.

The Annual Exhibition of the Northamptonshire Bee-Keepers' Association of bees, hives, honey, and bee appliances, will be held in connection with the Northamptonshire Horticultural Society, on Monday and Tuesday, Aug. 6 and 7, 1883, in the grounds of Delapre Park, Northampton, England. Practical illustrations of manipulating with live bees, showing the best method of driving bees, making artificial swarms, transferring combs from straw skeps to bar frame hives, finding the queen, extracting the honey without injuring the bees or combs, etc., will be given at intervals during the show days, in a tent specially constructed, so that visitors can see the whole manipulations without any danger of being stung. Prizes will be awarded amounting to over \$50.00. Entries will be received, and further information given, on application to Mr. James Davies, 33, Semilong, Northampton, by sending stamped addressed envelope. Entries close on July 31, 1883.

Mr. Alley's new book on *Queen Rearing* will hereafter cost \$1.25

Bee-Culture in India.

The London *Times* gives the following information respecting the bee industry in India, gathered partly from the *Indian Agriculturist*. The details were obtained by Mr. John Douglas, superintendent of telegraphs, from Mr. Morgan, deputy conservator of forests, and are noteworthy from the light they throw on the modes of collecting wild honey:

The best honey producing flower of Southern India, is the strobilanthes, which not only forms the principal undergrowth of the sholas, both temperate and tropical, but spreads over the grassy slopes of the higher elevations. There are immense numbers of species in this genus, and they almost all flower once in seven years, dying down entirely, and afterward a fresh growth springing up from seed. Whenever any species of strobilanthes flower, colonies of bees migrate from all parts of the country to feast on the honey, and rear their young brood. At such times honey becomes plentiful and cheap, and as the strobilanthes honey is of the finest quality and flavor, rivaling that from the famous Mount Hymettus, it is eagerly sought after by the Todas of the Neilgherry Hills, and, in fact, by all aboriginal tribes. The year 1879 was such a season for honey that it sold at the rate of four annas per imperial pint, whereas its usual price is from eight to ten annas. This honey, in the cold climate of the Neilgherries, crystalizes in from a fortnight to three weeks, when the flavor becomes richer and finer.

In the Wynaad, as soon as the moon has waned sufficiently, great preparations are made to take the honey. Bamboo and rattan ladders are constructed, sometimes of astonishing length, and at nightfall, after 9 p. m., for the bees do not go to rest until then, as you will find to your cost if you disturb them, the jain (honey) kurumbars proceed to the burray, and having erected their ladders, if they have to climb upward or suspend them downward, arm themselves with torches and knives, and sever the combs from the rocks or branch. The disturbed bees, meanwhile, roused by the glare of the torches, desert the combs and buzz aimlessly about, even on the persons of those engaged in taking the combs, but never attempt to sting unless crushed or hurt. The combs are then lowered down in baskets, the kurumbars feasting on the larvae, which tastes something like cream, while the fish, which swarm in thousands when the hives are built over a river, have a glorious feed on the grubs and bees that fall into the water and float helplessly down the stream.

The Coorgs make some attempt at bee-culture, and practice the industry to some extent in their own homes. The bees are domesticated, and the hives, which are of a very primitive description, made merely of the hol-

lowed out trunks of trees, are placed near the houses. The Coorgs have, however, no notion of collecting the surplus honey by any of the contrivances now in use.

In Cuddapah wild honey is collected also from the cliffs and ravines of the district. The process adopted in both is perilous and exciting, and the Yanadies alone are able to climb into the difficult and apparently inaccessible places over perpendicular cliffs, in some places from 100 to 200 feet in height. They do this by the aid of a plaited rope, made of young bamboos tied together. This rope sometimes gives away, the result being a terrible accident. It is a very nervous sight to watch the men climbing up these frail supports, and it reminds one of the egg-collecting process in northern latitudes. The men from below look like little babies hanging midway, the rope being fastened on the top of the cliff above by means of a peg driven into the ground, or to the trunk of a tree, the man swinging midway with 100 feet or so above and below him, and armed with a stick and a leather basket. The Yanady first burns some grass or brushwood under the hive, by which he pokes with his stick, holding out his basket at the same time to catch the detached portions of comb. When the basket is full he shakes the rope, at which signal his comrades above draw him up. The bamboo ropes are left to hang often for years, until they rot away, for a rope of this kind is never used twice, a fresh one being made on each occasion, and at each place.

South Canara is also a great honey district. The honey and wax have, however, but little local value, a mound, about 25 pounds, only fetching R. 2 and R. 16. It is thought that much might be done to open up the industry by exporting the honey and wax to England, the latter being a valuable product, and one for which there is always a demand. The trade, at present in Indian honey, is almost entirely confined to wild honey; but as the keeping of bees is an industry requiring little or no capital, it is especially adapted to the people of India.

Should the returns obtained from the inquiries now made and set on foot by Mr. Douglas, show that it is worth while to introduce this industry in a practical form, then Mr. Buck, the whole subject having been placed under his department, may possibly see his way to making a decided effort to interest the people in systematic bee-culture with a view to the trade in honey and wax becoming ultimately a profitable one to the country.

Do not send coins in a letter. It is dangerous and increases the postage unnecessarily. Always send postage stamps, for fractions of a dollar, and, if you can get them—one-cent stamps; if not, any denomination of postage stamps will do.

Philadelphia Bee-Keepers.

Mr. John Shallcross, of Philadelphia, sends us the following item of news from the *Herald*:

The Philadelphia Bee-Keepers' Association met at the residence of Dr. Townsend, the President, 1514 Vine street, on Monday evening, May 14. An interesting essay upon the bee and honey, from the earliest times, was read by Dr. Townsend. Questions of a practical nature were read from the question box, and were answered and discussed by the members. Two handsome charts of the "anatomy and physiology of the honey bee, and its relation to flowering plants," by Mr. Frank R. Cheshire, recently procured from England by the Association, were exhibited and explained by the President. An observatory hive, with a nucleus colony of bees in full operation, was also exhibited by Dr. Townsend. Bee-keeping in Philadelphia is making considerable progress.

Ladies as Bee-Keepers.

Prof. A. J. Cook, of Lansing, Mich., gives the following on this subject in the *New York Tribune*:

Mr. Heddon constantly complains of over-praise of bee-keeping. He says they all do not "get there"—to success, I suppose he means. Of course it is not all sunshine in apiculture. Severe winters mow down the colonies. "Foul brood" devastates and unfavorable seasons, not infrequently, make the profits microscopic; while, worst of all, many lack true persistence to "overcome" till delayed success has chance to crown their efforts. Yet I could name hundreds, amateurs and specialists, who get pleasure and no small gain from bees, and they include many ladies. For instance, Miss West, of Flint, Mich., whose father owns 100 colonies, is a teacher in the public schools. Last June Mr. West was prostrated with typhoid fever, and his daughter took the whole care of the apiary during this most active season, and with success, though she cared for her father besides. A friend of Miss West taught a district school, and for recreation cared for a few colonies of bees, which in no wise interfered with her duties as teacher. The income from the bees exceeded that earned as teacher. Of course, many will not succeed in bee-keeping—only those who are punctual and observing of the needs of the myriad laborers whom they oversee. But to use this as an argument against the business, would be virtually to condemn every employment.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

The Standard Langstroth Frame.

JAMES HEDDON.

If I am not misinformed, Mr. Langstroth, after inventing his hive, issued a book, in which he gave the exact dimensions of his hive and frame. This was Mr. Langstroth's standard. The book did the work of introducing that hive and frame. That book gave the dimensions that I claim are the standard. Soon after, the National Bee-Hive factory was started at St. Charles, Ill., and made and sold these hives on the most extensive scale of any house in the United States, thousands of bee-keepers bought them, and have patterned after them, or, at least, the frame, ever since.

Mr. G. M. Alves, of Kentucky, submits the following propositions why 17 $\frac{3}{8}$, and not 17 $\frac{1}{2}$ inches, should be universally accepted as the standard length:

1. There are more Langstroth frames in use of that length than any other.

2. The largest manufacturers of hives, and the greatest number of them, have adopted this size.

3. This size will exactly take eight standard one-pound sections—a very important consideration with those who prefer to take their honey in frames.

4. The editors of the principal bee periodicals have, and do now, give this size as the standard, and (on the authority of the Editor of the AMERICAN BEE JOURNAL), Mr. Langstroth himself has approved the change. See AMERICAN BEE JOURNAL for 1882, page 251.

In reply, I will say: First, Mr. Alves is undoubtedly mistaken about there being very many more of the altered Langstroth frames in use than of the old standard. I have been agreeably surprised to find a much larger number of the true standard in use than I expected. But if the question of what is the true standard frame rests with numbers of them, then I will build a large "brick factory" run by an "engine," and make enough of the 17 $\frac{3}{8}$ to make that once more the true standard frame. I had heard that this principle applied to lying, that is, a man could tell a lie so many times that he would finely believe it himself, but until now I did not know that the true standard frame could be made the false one by making enough frames of an odd size. I dislike to make so many of these frames as to make Mr. Alves change all of his, but I see no other way to avert the trouble of changing my hundreds of hives and the thousands I have sold to others.

2. I admit that the largest manufacturers of hives have adopted the mongrel size, and for aught I know, originated it, but large folks are often in the greatest error, and "truth is often on the scaffold, and wrong often on the throne." This proves nothing but the mistaken method of Mr. A.'s reasoning.

The question is, "What is the standard Langstroth frame?" Not Smith frame, or Brown frame, or Jones frame? Let us stick to the subject.

3. Mr. A. tells us that the new mongrel size will exactly take 8 standard one-pound sections. In reply to this, which has no bearing upon the question under discussion, I will say that the Langstroth brood frame does not take sections at all. A broad frame can be perfectly fitted to the true standard, and the 4 $\frac{1}{4}$ sections at the same time by just making the end pieces a trifle thinner. Further, that this style of adjusting sections is now doomed, and is rapidly being superseded by much better methods.

4. This simply proves that editors can be mistaken; and further, Mr. Langstroth can no more change the standard frame than any one else; when he changes the dimensions, he simply gives us another frame; this second frame might become the standard, but it has not as yet. There is this one thing in our favor; wherever we find the true standard, we find the measurements accurate. Of

this mongrel, we find a great variation in depth, as well as length. The "large manufacturers" seem to get in too great a hurry to keep their machinery from varying, often times more than the difference over which we are discussing. If Mr. L. had made a few frames 17 $\frac{3}{8}$ and then abandoned them for 17 $\frac{1}{2}$, and booked this latter size, then I should say Mr. A. was right, but I find that he, after much figuring and experimenting, settled upon, and gave publicly to the world, the 17 $\frac{3}{8}$; and until he notifies us in the same manner that 17 $\frac{1}{2}$ is not the standard, we shall insist on it, that it is the standard Langstroth frame.

Mr. L. may now "prefer" the 17 $\frac{1}{2}$, but to entertain any such preference is scarcely based upon any laws in nature, but rather favoring some ones convenience in the matter; is it not? As regards the two lengths, we cannot believe that any one would realize any difference in them, except where fixtures were to be exchanged from one hive to the other, and in this case, many of us have done it successfully.

Dowagiac, Mich.

[The inventor of the frame, and author of the book, Mr. Langstroth, has publicly given his sanction to the frame 17 $\frac{3}{8}$ inches long. No amount of discussion will be able to change the thousands of both sizes now in use, and we fear none of the manufacturers will be willing to change unless an agreement can be entered into to make a new standard frame for America. This, in many ways, would be desirable if all would conform to it.—ED.]

For the American Bee Journal.

Central Illinois Convention.

In answer to a call for a meeting of bee-keepers of the association of Central Illinois, 22 members assembled at the Surveyor's office in Burlington, Iowa, April 11, 1883.

The forenoon session, which was a short one, consisted in the reading of the minutes of the previous meeting, the report of financial standing of the association, and giving some experiences in working with bees.

In the afternoon session the subject of "hives and sections" was taken up, and President Wolcott thought more depended on proper management than the kind of hive, for success.

Mr. Cox believed if we had a standard hive it would be much better, but did not expect such a hive would, very soon, become universal.

Mr. Butler asked what kind of frame was best to winter on?

Mr. Cox: A deep frame.

Mr. Corbett thought bees worked better in surplus frames at the sides.

Mr. Butler used the Langstroth hive, with frames running crosswise, and was decidedly in favor of the chaff hive for wintering, and the 4 $\frac{1}{4}$ -x4 $\frac{1}{2}$ section for surplus.

Jas. Poindexter considered large

frames better for finding the queen or manipulation, as a less number are required in a hive, and it did not take as much time, as if the frames were smaller and more of them.

Mr. J. Kuran thought short frames more easily manipulated; he liked single-walled hives better than chaff hives; they were more easily handled.

Mr. Smoot preferred the American hive with the cap to slide down over the lower hive, in winter. He was very successful in wintering, but gave no upward ventilation.

Mr. Funk used the chaff hive for winter, and let the snow remain around the hive until it began to thaw; then remove it to keep the hive dry.

The next subject was "swarming," and Mr. Hayes made artificial swarms by taking three frames of brood and bees from the old colonies as often as they could be spared, and in this way, last season, increased from 2 to 13 colonies.

The next subject was "bee pasturage," and Mr. Wolcott thought there was a marked difference in bees kept in the city and those in the country.

Mr. Cox thought that, in good seasons, if the honey was taken away as fast as collected, there would be but little difference.

Mr. Funk was asked if he noticed whether his bees gathered any honey during the first part of last August. He said there were but few days that his bees did not get some honey, and that was during stormy weather.

"Different races of bees" was next discussed.

Mr. Kuran: Holy Land bees were very prolific, but no better honey-gatherers than Italians; he could tell the Holy Land bees by their peculiar motions; they were worse about robbing. Black bees were bothered more by the moth.

Mr. Funk said the Holy Lands were very sensitive, and took some time, after being handled, to become quiet. They did not properly seal their honey.

The next subject was "queen-rearing," and Mr. Kuran had not noticed any difference between artificial and natural queens.

Question by the President.—Are imported queens any better than those homebred? Answer by Mr. Kuran: He could not see that they were better in any respect.

The next subject was "marketing honey." Mr. Cox said he could get twice as much extracted as comb honey, and, with him, it was the most profitable. He sold extracted clover honey at 10 cents, and fall honey at 9 cents per pound. He thought it best to cultivate a home market, by retailing at wholesale price.

Mr. Wolcott said if people were acquainted with the real value of honey all that could be produced would easily be disposed of. Adjourned.

JAS. POINDEXTER, Sec.

The Central Kansas Bee-Keepers' Association will meet at Manhattan, Kansas, on June 30, 1883.

For the American Bee Journal

Clipping Queens' Wings.

DR. G. L. TINKER.

A few bee-keepers, including Mr. G. W. Demaree, think that the clipping of queens' wings is liable to injure the wing-power of worker bees.

As this is a question of much importance to all bee-keepers, it should have thoughtful consideration. For myself, I should dislike greatly to have my queens go unclipped. But if it could be shown that there is danger from the practice, it would be discontinued.

The fact that a colony in a very large hive, in some instances, never swarms, is evidence that some queens do not again take flight after the time of mating. It is exceedingly rare, if it ever occurs, for a fertile queen to leave the hive except with a swarm. Hence, in a non-swarming hive, the queens' wings could be of no use to her after fecundation, and it would not matter whether her wings were clipped or not. Probably, Mr. Demaree, nor any one else, would venture to assume that because the laying queens of non-swarming hives rarely or never take flight, that eventually the worker bees would, in consequence, suffer a loss of wing-power.

As the clipping of queens' wings is never practiced except upon the fecundated queen, it seems to me that there is nothing analogous about it to the domestication of fowls, which, from ages of confinement, has resulted in a loss of their wing-power. If, however, a plan of artificial fertilization could be devised by which the mating of queens could take place without having to take flight, then we would have, no doubt, an analogous case to the domestication of the common fowl, and, after many years of such practice, we might have worker bees going "on their bellies" after nectar.

The question therefore arises: Is not the fact that the virgin queen is rarely, if ever, mated except upon the wing, a wise provision of the creator against the possible loss of the wing-power of the worker bees, either through natural processes, or the hand of man in securing artificial fertilization?

I take it that Mr. Demaree's suggestions are applicable, not to the clipping of the wings of fecundated queens, but to the proposed and attempted practice of artificial fertilization, which would necessitate more or less of confinement of virgin queens. In view of the possible dangers indicated by Mr. D., may we not be thankful that it has never been accomplished in a practical manner, and hope that it never will be.

But the proper clipping of the wings of laying queens cannot, in my estimation, be considered in any sense injurious, and I shall continue the practice for the many well-known reasons that have been given.

HIVING SWARMS.

After the swarm is out and the queen found and caged, the old hive is

moved back and covered with a sheet, the new hive to be set in its place with the caged queen near the entrance. To prevent the returning swarm from going into the adjoining hives, I take off the covers and set up in front of them, or sheets may be thrown over them. After the bees get well started into the new hive the queen is liberated. The swarm is readily hived, and when set upon a new stand, will work just as well as if a great din had been made upon the dinner-horn and a lot of tin pans, before clustering in some tree-top to be hived in the ordinary manner. By the way, there is less danger of a swarm going to the woods at once where the queens' wing is not clipped, than of its bidding good-bye to the new hive and the bee-keeper a few hours after hiving. By having the queens' wing clipped, this annoying dilemma is avoided.

HOW TO CLIP THE QUEEN'S WING.

The comb on which the queen is found, is lifted out and hung on a revolving stand for the purpose, or it may be leaned against a hive. With the thumb and finger of the right hand, lift gently the queen off from the comb by the wings—not one wing. With the thumb and finger of the left hand, take hold gently of the queen by the thorax, or middle part of her body. Do not let go of the wings until she is held firmly, but very carefully, in the left hand. Then with the right hand take a pair of sharp-pointed scissors and steady the lower blade upon the second or third finger of the left hand. About one-half, or nearly one-half, of the *thin edge* of only one of the large wings is cut lengthwise, or nearly so, of the wing. By this means the deformity can be hardly noticed, which is a matter of some moment to me, since I believe it to be cruel to cut more than is necessary, and injuries to cut the wings squarely off. By the method here given the queen goes about her duties as if nothing had happened, and I have yet to see that it is in any way detrimental.

With bee-keepers having large or stiffened fingers or who are very nervous, it might not be safe to handle queens in the manner here given. In such case, the lady of the house could perform the operation as dexterously as any one.

New Philadelphia, O.

For the American Bee Journal

The "Strained" Bees.

W. H. SHIRLEY.

After reading Dr. E. B. Southwick's remedy for the small section craze, on page 256 (May number of *Gleanings*), I commenced to take his remedy, and it has made me feel so much better that I have sent to the Doctor for a prescription for "the strained bees."

We take the Doctor to be a homoeopathic physician, and if we understand rightly, their way is to test the strength of all medicines on themselves before giving to their patients.

That is why we put so much faith in the Doctor.

I believe Mr. Heddon was the first to cross dark leather-colored Italians with brown German bees. From this cross sprung the famous red-clover strain.

From Mr. Otman's report, backed up by sales of honey, we should say white-clover strain for Mr. O.

B. F. Carrol, of Texas, must have a new strain; and now Henry Alley, of Wenham, Mass., is out with a winter strain—needing but little honey to winter them. Next, some one will have a strain that lives all the winter without eating *any* honey. Followed by another strain that gathers from 100 to 200 pounds of nice white honey where our common bees would starve.

Believing in the old adage, "An ounce of prevention is worth a pound of cure," we sent to the worthy Doctor of Mendon to be prepared for the "coming" *Apis-Americana*. Could we have had the next to the last named strain of bees, during the past winter, we should have been 20 colonies better off, as our fancy strain were perfect gormandizers, and the 20 colonies died for want of food.

Now, we are longing for the last-named strain; particularly the honey part. As the truth must be told, (I have just taken another dose of the Doctor's medicine), our golden strain only gathered 20 pounds of surplus, per colony, spring count, last year. Not much of the ring of gold about that, except the ring of truth!

But, if the Doctor's prescription, sent for, does not make us sick, followed by too big a honey shower, we hope to speak better of our dark ringsters; for they are stronger in numbers, at this time of year, than we have ever seen them before.

And, Mr. Editor, if we make a report of a large honey crop, we will back it up by showing bills of sales.

Last winter I wintered my bees on something of a new plan (to me at least), and as I never saw it in print (although it may have been there a dozen times, as I have not time to read one-half that is written), perhaps I will try my pen at a description, when in season, and safe from being called a winter crank.

Glenwood, Mich., May 17, 1883.

For the American Bee Journal.

Northern Ohio Convention.

The Northern Ohio bee-keepers held their spring meeting at Norwalk, O., May 2, 1883. The president not being present at the hour appointed for opening the meeting, Allen Bartow, of Milan, O., was chosen temporary chairman. The secretary's report of the last meeting was read and approved. The treasurer's report showing a balance in the treasury of \$10.45.

C. D. Bennett, of Elyria, O., B. P. Whitney, of Kipton, O., and Peter Biermacher, of Avon, O., joined the Society, which now numbers 43 members. After the enrollment of new members, the president having arrived, took the chair and called for

the reading of the first essay, which had been assigned to Allen Bartow, of Milan, as follows:

PRODUCING SURPLUS COMB HONEY.

Having been assigned the task of writing an essay on the subject of comb honey, or how to obtain the largest crop of the same, I shall state that we must have the largest crop of working bees in each hive to obtain it; now, how shall we obtain the bees?

If we commence in the spring with good, healthy bees, either blacks or Italians (for I ignore all others), we must first learn their exact condition as to strength and numbers, then use good judgment in building them up to full strength or capacity of hive (movable frame of course), and by manipulation hold them up to this; now comes the all important question, how shall we do this? Each bee-keeper must decide for him or herself; but I suppose I am expected to give some plan, and shall do so to the best of my knowledge of the subject, which is the following:

Treat your bees as you do your other farm stock, encourage breeding by giving them warm quarters and plenty of food; it is not enough that there is plenty of honey in the hive, any more than it is enough that your cow has plenty of hay or straw—spring having arrived, both bee and cow require a change of food, if they are to successfully bring forth and rear their young, and give you a profitable surplus; then I would say, stimulate your bees in every possible way to breed and rear bees for the time maples are in bloom until fruit goes out of bloom, and white clover comes sufficient to give full flow of honey.

Now, how is this to be done? If the colony is light, reduce the size of brood-chambers (by means of division boards or otherwise), to the number of combs upon which the bees cluster, removing the other combs beyond or behind the division-board, leaving room underneath the division-board for the bees to pass and get the honey from them, not forgetting to narrow the entrance to the hive to prevent robbing; now prepare feed of thin syrup of granulated sugar, or sugar and honey, and feed it on warm evenings in front of the hive at sundown, in a feeder that prevents drowning of bees, and remove your feeder in the morning, replacing entrance block to narrow the entrance, and prevent robbing. The feeder should be made to fit the entrance, while feeding the colony. Now, when combs become crowded with bees, move back the division-board and make room in centre of cluster for another empty comb, put it in, and when again crowded, repeat as before until the hive is crowded with bees with full combs and board removed. In a day or two prepare for surplus, in this way: Remove from the hive a frame of comb filled with honey ready to cap, and put it at side of surplus box, putting next to it a frame of sections filled with foundation, put in division-board next to surplus frame and cover down the brood-chamber. As soon as bees get crowded, and are working in sections.

add more surplus frames until your surplus chamber is full of frames, then as each frame is filled with honey remove it and put in its place empty frames of sections. Look to your brood-chamber, removing all queen-cells, and keeping your queen supplied with empty comb in which to lay. If you lose your queen, replace by introduction a fertile one at once.

In conclusion I would say, that the treatment would be proper in case the colony is a strong one.

Milan, O.

The president said place a comb filled with liquid food between two combs filled with brood, and it would stimulate brood-rearing better than any other method he had ever tried. Must be careful not to spread brood combs too often. The brood might become chilled.

Mr. Smith said he used a mixture of granulated sugar and buckwheat flour for stimulating, with good success.

Mr. Johnson said, he fed in a feeder placed on the top of brood combs with cushion placed over it.

Mr. Whitney said, he had a colony in his cellar which he found floating in 18 inches of water during the winter, which was now in good condition.

Mr. Boardman said, he would not spread brood combs at this season of the year, as bees now are reduced to their smallest numbers, and there is great danger of brood being chilled.

Mr. Whitney asked if spring feeding had proved successful when practiced during cold weather.

Mr. Fish said, he would not feed during cold weather if bees had an abundance of stores. He would feed those only that were destitute.

Mr. Bartow said, he would reduce the space occupied by each colony to such size by the use of the division-board, as would enable the bees to cover all the combs all the combs, and thus the requisite amount of heat could be kept up.

The next essay was by H. R. Boardman, as follows:

THE MOST PROFITABLE RACE OF BEES.

One of the most prominent objects of my early boyhood recollections, is the old box bee-hive out in the garden, under an old apple tree, with its inhabitant, the black bee. By the hour have I laid on the grass under this old apple tree, and watched with eager interest, those mysterious little workers.

Many wonderful things had I been told about them, and the economy and government of the multitudes within their well-guarded home; which, to me, was shrouded in the deepest mystery, and their well-kept secrets, guarded with a dignity and honesty which I had never presumed to question. I had been told that they had a form of government like a nation of people, and had a king who sat upon a throne, and all his subjects paid implicit obedience to his commands and rendered the utmost respect to his sovereign wish, and I had noticed upon all combs, that had been removed from the hive, undoubted proof of this. The throne upon which the king sat, I have since learned, were

old queen-cells. I had been told that these communities were systematically divided, and that each division had its particular work to perform, and leaders or overseers were placed over them to superintend the work in each department; and some were assigned the position of guards at the entrance of the hive, and did not have to gather honey.

I watched them swarm with more than idle curiosity, and I heard older people say that when the swarm issued they followed the king out, and wherever he went they followed—and if the king died in a colony, they would all stop work and would never do anything more, and would finally all die. I watched them toil the summer through to accumulate their sweet stores of food to provide for the coming winter, only to be robbed of them and cruelly murdered in the fumes of the foul brimstone pit. I said it was cruel and wrong, and that there ought to be some other way, and if their stores must be procured in that piratical way, although honey to me was a tempting luxury, I preferred for one to forego the pleasure of such luxury.

How did any one learn these wonderful things, I said, unless by patient and careful watching, and if others had discovered these wonderful things, why not I, by patient observation, penetrate the mysterious precincts of these wonderful little insect people? And I did watch with all the energy awakening curiosity could arouse, and I listened often with my ear close to the hive, to their mysterious bee talk; but their secrets remained untold, and their every movement remained a dark, unsolved enigma.

But a new era came, light dawned. There came the movable frame and the new bee, the yellow bee, with its wonderful reputation for penetrating the depths of the rich red clover. And what then? Then came a knowledge of those mysterious things within the hive; improvement and progress in bee-culture; old superstitions vanished, new and startling truths were brought out, until that mysterious hive of 20 years ago is to-day a thing of practical fact, within the comprehension of the veriest novice. Italian queens were introduced into our colonies of black bees, and in an incredible short time the whole colony was changed from black to yellow bees, discovering the startling fact to even old bee-keepers, of the brief, almost ephemeral existence of the honey-bee during summer.

So readily was this change made, and so apparent the benefits gained thereby, that Italian queens were rapidly imported, queen breeders spring up over the land everywhere, and the queen has become a common article of trade in the market of bee-keepers' supplies, and the superiority of the yellow race of bees over the black, became almost universally acknowledged. But a mountain of difficulty arose in the pathway of queen venders, especially importers. A standard of purity was necessary to preserve the reputation of the imported stock, and distinguish it from the

plebeian race, but in attempting to establish this, it became apparent that even the imported stock would not stand any single test, so various were their markings and characteristics. Suspicions were awakened among unprejudiced bee-keepers that the race of bees from which we were receiving importations, were not a pure race, and this suspicion has been strengthened into fact, by the knowledge that black bees are found in Italy. As a result of these variations, different strains of bees began to be brought to notice, each possessing particular, valuable qualities as set forth by their particular champions; and many a sharp contest has been carried on in the bee papers, by the advocates of some particular stripe, or tint, or tinge in his favorite strain, and now we have almost as many strains of bees as there are breeders.

Who that has read the bee literature has not a vivid recollection of the sharp criticisms upon the dark queen, sent out by Messrs. Dodant; even unkind reflections upon their integrity. They have outlived it all, and float successfully now above suspicion.

Some breeders take pride in publishing what they no longer hesitate themselves in believing—that they are breeding a cross of the black and yellow race, and no longer consider yellow bands a test of excellence, or a guarantee of purity, and that although beauty and amiability may be desired, they are too often obtained unwisely, at a sacrifice of more sterling qualities.

The reports of large yields of honey coming from colonies not possessing the requisite number of yellow bands to entitle them to a certificate of royalty, has become too frequent to be accidental, and the wise apiarist will hesitate long before superseding the queens of such colonies with those having the regulation markings.

We are, without doubt, largely indebted to the introduction of the yellow race of bees into this country, for the knowledge and improvements in modern bee-culture.

But while Mr. A., and B., and C. have made a paying business rearing queens, and have made a hobby of yellow bands and golden tints, we, as practical bee-keepers, are looking to a different source for our revenue, and are only anxious how we may obtain large yields of honey. Beauty and pleasure are secondary considerations. Honey gathered by the black or hybrid bees, brings as much money in the market as that obtained by the most beautiful golden Italians—and in fact, it is claimed that honey comb made by the black bees is whiter and more delicate in appearance than that made by the yellow race.

But what shall we say of the new races more recently introduced into this country by Mr. D. A. Jones, of Canada, at such great expense both in time and money? The Cyprians and the Holy Land bees, what can we say of them? except that they are an experiment, and like all experiments in bee-culture, should be tried with much caution. There is an old maxim, "Let well enough alone," not altogether a noble one, yet for all that,

successful for the moderately ambitious, and perhaps a very safe one for the average bee-keeper. We can but admire the enthusiasm of Mr. Jones, which has prompted him to such untiring energy, and to make such sacrifice of time and money in his search for some superior race of bees, by which he might benefit mankind. And Mr. Frank Benton, too, his assistant, has done much to command our esteem and admiration.

But all great enterprises of this character are measured by their ultimate success or failure. The reports that have already been received from his importations, seem to promise but little or any improvement upon the yellow races of bees already so universally diffused over this country, of which I prefer to consider them only a strain—and, indeed, the Cyprians have already gained a reputation of being very un-amiably in disposition; and often becoming angry without provocation.

By what name, then, shall we know the coming bee? We might adopt the phrase used by Mr. Heddon, and applied not to bees, but to bee-keepers, "Get there success," as it is very comprehensive of the qualities we think essential, but we prefer that other, more beautiful and more significant name, already heralded forth among progressive bee-keepers: *Apis-Americana*.

Townsend, O.

C. E. Newman asked if Cyprians or Holy Land bees had proven more profitable than the Italians.

Mr. Boardman said, he thought the Italians were the most profitable.

S. F. Newman said, he had tried both Cyprians and Italians, and in his experience the Italians had proved to be fully equal to the Cyprians as honey gatherers, and were not as irritable. At times it was almost impossible to handle the Cyprians unless they were chloroformed.

Mr. Bartow said, he preferred hybrids to Italians; they protected their stores better than other bees.

Mr. Bartow asked whether Holy Land bees were more likely to be pure than the Italians.

Mr. Boardman said, he thought the Holy Lands as likely not to be pure as the Italians.

The President:—We are ignorant as to the fact whether the Cyprians are indigenous to the island of Cyprus, or whether they were Italians modified to a certain extent by climate and other causes. The important question to be decided is, which race of bees will give us the largest amount of honey, and thereby fill our pockets with money. He wanted no pure bees, but preferred hybrids.

Mr. Whitney asked Boardman which produced the best workers, an Italian queen mated with a black drone, or a black queen with an Italian drone.

Mr. Boardman: did not know which would produce the best results. The facts are that Italian queens generally mate with black drones.

Mr. White: an Italian queen mating with a black drone produces better workers than the reverse.

The next essay was by D. White, as follows:

PRODUCTION, CARE AND SALE OF EXTRACTED HONEY.

I received a notice from Mr. Newman, a few days since, saying we shall depend upon you for that part of the programme, namely: "The Production, care and sale of extracted honey." I believe this subject should be discussed freely, and, no doubt, some one else could have been selected that could come nearer doing justice to the subject than myself.

For the past three years it has been my hobby to procure almost entirely extracted honey. The first season I took all my honey from brood-chamber. Second season, from brood-chamber, and some from surplus chamber. At the commencement of the season, or when I commenced extracting, would take all I could get from each colony, but after that commenced, being careful by taking about half each, so on until the last work was to take only one side comb from each colony; this I would keep up as long as they were able to fill the empty comb. This was my plan of working safe, and in case the honey flow should shut off (as it frequently does without any warning), I would have plenty of honey left for winter purposes.

I fancy a great many who have used an extractor, have done so without using any judgment. Hence, their bees were compelled to go into winter quarters with nothing but late unsealed stores, and the consequences were heavy losses during the winter. The honey procured during the two seasons mentioned, was about 75 pounds to the colony, on an average, each season. I was obliged to work very hard, and compelled to visit a hive too often; but had no notion of going back to comb honey. I use chaff hives that take Langstroth frames, 10 frames below and 13 above, and, last spring, I was ready with enough wired frames filled with foundation to fill the surplus chambers to 80 hives.

We must take into consideration the amount of comb work that had to be done; about 1,000 sheets of foundation was worked into comb. My extracting, last season, was entirely from above, and I procured enough honey so that I sold 8,000 pounds with enough left to winter—and 1,000 pounds held in the combs to use this spring, if needed—I call this a reserve, and expect hereafter to have plenty of honey in the same shape every spring. The bees gathered it, and if they fail to need it to carry them until the honey comes again, they will certainly have enough, so that the first day's work they do will be done for me. I weighed what I extracted from one of my strongest working colonies and it gave me 213 pounds, and I think I had several that did equally as well.

My theory, to procure plenty of extracted honey, is first, strong colonies; second, plenty of room for the bees to work, and the next thing is for the bee-keeper to roll up his sleeves and work too. It is no place to put a man

that does not like to work. I was entirely alone with my 80 colonies last season, and I worked hard enough so that only 3 colonies cast natural swarms.

I do not tell this, wanting you to think that I like to work so dreadful well—for I do not—but, last season, I was forced. I think I am safe when I say I could have procured at least 1,000 pounds more honey than I did, had I had good help; that is, I lacked that much of working the bees for all there was in them. This loss came from not getting around to extract the second and third times as soon as I should, by from three to four days, which makes a great loss, when behind that way on a large apiary.

I believe we all want to make this business as remunerative as possible. I read and hear a great many splendid reports from men that produce entirely comb honey; am glad to know that such is the case. I believe it our duty to supply the demand for both comb and extracted honey. It would be too much like all belonging to one church for us all to procure one kind of honey.

We that procure extracted honey must get about double the weight that our brother bee-keepers do that procure comb honey. If we fail to do this, they will get more money than we do. Then another thing we must make up our mind to do; we must work harder than they do, for while we are working early and late, carrying heavy combs and wielding and uncapping knife, they are doing what I call puttering around, hiveing now and then a swarm, and the rest of the time waiting for section boxes to be filled and completed. We do not want to make them feel bad, and do not think we shall, but I believe we have got a large per cent. the advantage over them in a short honey flow, and I believe it the characteristic of this section of the country to usually give us short seasons.

Now, suppose we have plenty of nice straight combs in wired frames (and they must be wired for we do not want the combs tumbling out and smashing to pieces), and we have filled our surplus room, ready for the first honey to be found in white clover—all our bees have to do the entire season is to gather honey and deposit it in our empty combs—then I believe bees will work stronger on large combs than on small combs in section boxes. It must be an extremely short season if we cannot extract, at least on an average, 75 pounds to the colony of good, ripe honey—13 combs once filled will more than do this. Now, how would it be with 80 pound sections in one of these hives; a few completed out of the number ready for market, and the rest all the way from not being touched at all to half and two-thirds completed, and a lot of unsalable nubs, I call them? This is in a short honey flow, understand, and season shut off, leaving everything as I have tried to explain it.

I may be wrong, but we are here to learn, if possible, from each other, and if we can tread on the toes of our brother bee-keepers that procure comb

honey, it may be the means of fetching out something that will be a benefit and do us all good. I believe there are too many men that keep bees that think they know it all. Any how, it seems to be my lot to run across such men; especially men that have always kept bees and will not try to learn what they call new-fangled things. You will see these men with a rag rolled up for a smoker and drumming a tin pan when a swarm is out. I mention this, for I believe we are never too old to learn. When I first commenced with bees I learned to play quite well on a tin pan, cut off virgin queens' wings, and several things that I do not do now.

Care of extracted honey occupies but little of my time. I have tin cans, capacity about 500 pounds, with large gate to draw out the honey. I tie over cans securely, cheese capping cloth, letting it bag enough to hold a large pail full; and when that much comes from extractor, I carry it into a dry honey house and empty into cheese cloth to strain, while I am filling the next pail of honey. I believe it a good plan to store in 10, 15 and 25 pound cases ready for market. Extracted honey will candy in from 4 to 6 weeks after extracting, and I believe it will not be very long before it will sell best in a candied state, especially when people learn that candying is a positive proof that it is pure unadulterated honey. We know of no other liquid sweet that will candy. Candied honey can be put back to a liquid state by warming gradually, as often as desired, without injuring the flavor, but must not come to a boiling point.

The sale of extracted honey seems to be the great trouble with some, but I believe it can be more readily sold than comb honey, and in very much larger quantities, for the following reasons: It is sold for about half the price of comb honey, and comes within the reach of every family. But the most important thing of all is, never to sell a poor article. Never extract a comb unless it is sealed as nice as any section-box honey. It takes elbow grease, and will give most anybody the backache. But we must come to it, if we expect to build up a trade on extracted honey.

It is very easy work to empty combs of thin, unsealed honey, and not a very hard task to extract when only half of the combs have to be gone over with an uncapping knife; but my opinion is to not sell such honey. I do not believe any one can build up an extensive trade with such stuff, and know he cannot if he comes up in my territory. I have built up a good trade, and have done so with a first-class article.

About 4,000 pounds were taken from my door, last season, by customers that came with pails, cans, crocks and jugs to carry it in, and they kept coming long after my honey was all gone. I had a wagon on the road peddling about one week, and could dispose of about 300 pounds a day in this way. Go where you will, you will find more or less people down on strained honey, as they call it; but my plan from the

start was to give such people a saucer of honey if I could not persuade them to buy, and in nearly every instance it has made me a steady customer; some that were so prejudiced on the start, now buy, each season, from 50 to 100 pounds. I have a host of customers that work by days' work for a livelihood. They can afford it, and will buy at 11 cents a pound, while but few of this class will look at comb honey at from 18 to 22 cents per pound. I think I gave this a fair test last fall, with all classes, when peddling. I had comb honey in section boxes, letting any one take their choice, 11 cents for extracted and 18 cents for comb, and I had a few sections left out of 100 pounds while I was disposing of about 1,800 of extracted.

There would not have been as much difference as this had I not put more force on the extracted, telling them all the difference there was, the extracted was out of the comb. I told them facts, and after tasting and examining for themselves they would conclude to take all or part extracted. I have a great many customers that want a little comb honey each season. They want it for special occasions. One steady customer of this kind is my wife, and I am ready to agree, when we take looks into consideration, we must fetch out the comb honey.

I will close by saying we can keep a strong colony of bees under control, scarcely one will cast a swarm if attended to in the proper time, that is, combs taken out and extracted as fast as they are sealed and ready, and if increase is wanted it can be done after the honey flow, and to make it safe, save plenty of good sealed stores to give the colonies we build up. I, last season, increased from 80 to 120. In my home apiary, I now have 100 rousing colonies, did not lose one, and not a weak one at the present time. I lost 4 out of 20 two and one-half miles from home. Cause, not properly cared for. I did not fix them for winter as I should. I used the old-fashioned way too much—guessed at it. Guess work will not do in the bee business, any more than any other.

New London, O.

Mr. Burtow: How many times do you extract from the same colony during one season?

Answer: As many times as two or more combs in the upper story are perfectly sealed.

Mr. Whitney: How do you prevent the queen from laying in the upper story?

Answer: I do not prevent it, and it is not necessary, as it does no harm.

The comparative profit of producing comb and extracted honey was thoroughly discussed by nearly all the members present, without arriving at any definite conclusion.

The Berlin Fruit Box Company had on exhibition some very fine one-piece sections, and Newman Bros., of Norwalk, some Quinby smokers.

James Gibbs, the treasurer, having resigned, Edwin Gibbs was chosen to fill his place, and Miss Eliza Moon of Milan, was chosen vice-president.

After a vote of thanks to Norwalk City Council, the convention adjourned to meet at the call of the secretary, sometime during the month of October, 1883.

S. F. NEWMAN, Sec.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Queries About Extracting Honey.

Will Mr. Heddon please answer the following questions:

1. Will it do to extract honey the next day after it has been deposited in the cells by the bees?

2. Are one-story hives as good for the production of extracted honey as two-story hives?

3. How many 12x12 inch frames should there be in hives, when only of one-story?

4. How can we ripen the honey after extracting, to make it keep well?

5. Is there any way to ascertain a good day for honey-gathering, by the indications in the morning?

Nineveh, Ind. W. D. SMYER.

ANSWERS.—1. Not if the honey is intended for sauce. If for manufacturing purposes, it will, if the nectar is of good quality.

2. Not for my use. I have tried both thoroughly, and much prefer the 2-story system. Some experienced and successful producers differ with me, but I must answer from my own experience.

3. I should want as many as 25 at least.

4. I have tried all plans, except sun evaporation, and I find no method equal to the old-fashion one of letting the bees ripen and cap it, when it will be rich and oily, and not nearly as liable to grain or sour. The best methods I have used, is to store the honey in one-gallon crocks of stoneware, and pile them up, with sticks between them, and keep in a dry room, with screened windows and a free circulation of air. All double-walled or cool rooms will be damp.

5. Electricity, that great mover of all that stirs, that other name for heat, light and motion, is the honey producer's friend; when the morning indicates a day of electric conditions, I look for a good secretion of honey.

The Lye Process.

Mr. Heddon, in some of the back numbers of the BEE JOURNAL, you speak of the lye process for making the sheets of comb foundation, let go of the press, etc. Do you still use it?

How do you prepare the lye? Do you rinse the sheets afterwards?

V. W. KENNEY.

Shirland, Ill., May 22, 1883.

ANSWER.—Of all that slips and slides, lye is the "slickest." Get the best concentrated lye—poor stuff is no go. Louis Menzes Co. is the only good kind we can get out of many brands. Put 2 tablespoonfuls into a quart of water. With a brush made of a handful of broom corn, wound with stovepipe wire, lye the book thoroughly. Now don't be afraid of the effects of the lye on the book. It will not injure it nor the foundation. Drop a piece of foundation in this strong lye solution; leave it there a week, and notice that it does not effect it at all. The lye solution, when on the foundation in large quantities, precipitates and losses its strength, so that the white powder it leaves can be tasted on the tongue, and only a brackish taste is perceptible. To put to the bees it is perfectly harmless. We use a cheap brush because the lye eats up a brush in three or four hours. The dies must be cleaned of the particles from the eaten brush, every two or three hours. To keep the fingers from being eaten through the skin, dip them every few moments in strong vinegar. Do not get any vinegar (not a drop) on to the dies. You will omit to dip your fingers into the vinegar often enough, at first, but you will soon have a gentle reminder, in the shape of a sore, that will sting like a bee when lye touches it. With some die books, and on certain days, we run off 100 sheets with once using the lye on the book; but, at other times, only two or four sheets without having to touch the book in places with the saturated brush. The above is the general outline.

Convention Notices.

Convention in South-Western Iowa.

All who are willing to help support a convention in the South-Western counties of Iowa, will please drop me a postal card. Who will be first?

T. A. HORGAS.

Henderson, Iowa, May 21, 1883.

The Warren County, Kentucky, Bee-Keepers' Association, meets at Smith's Grove, Ky., on June 2. A large attendance is expected.

N. P. ALLEN, Sec.

Renewals may be made at any time; but all papers are stopped at the expiration of the time paid for, unless requested to be continued.

SELECTIONS FROM OUR LETTER BOX

Bees Gathering Honey.

Bees are doing well—taking in honey fast from black locust; white and red clovers are coming into bloom. I have 63 colonies.

WM. HAMILTON.
Louisville, Ky., May 17, 1883.

Bees Building New Comb.

My bees built some new comb in the small sections from apple tree bloom, but did not complete any. My colonies are now very strong, and have mostly nine full frames of brood. There will be a great amount of swarming in this section, this year.

DR. G. L. TINKER.
New Philadelphia, O., May 21, 1883.

What Became of His Bees?

Neighbor A. had two colonies of bees last fall; this spring one was dead, the other good and strong. He cleaned out the hive in which were the living bees, and while doing so set the frames (and bees) in the hive that had contained the dead bees. After having nicely cleaned up, he thought the bees might as well stay where they were and save the trouble of replacing them in their own hive. So he placed them on their own stand and took their own hive away. After a few days he opened the hive, when, lo! not a hundred bees were found. Now, he is anxiously inquiring of his neighbors, who are amateur bee-keepers, "What became of my bees? Can you tell?"

J. B. CRAIG.
Beatrice, Neb., May 21, 1883.

[It is a case of abnormal swarming. The hive was distasteful to the bees, and they "left for parts unknown." Perhaps it was quite dirty, much bespattered by the diseased bees that finally died in it, and the bees placed there against their will, concluded to "take to the woods," rather than remain in a hive that was too highly perfumed for their comfort.—ED.]

Bees in Good Condition.

I have 36 colonies of bees now, in good condition; I lost 8 in the winter; 5 of them by neglect, on account of being away from home.

E. S. HOVEY.
Swanton, Iowa, May 17, 1883.

A Cold Wave in Kentucky.

Notwithstanding the weather here has been very changeable, the season so far has not been altogether unfavorable. My bees have built up rapidly, and have done well on fruit bloom, dandelion, etc. Locust opened on the 13th inst., and gave a deluge of nectar till cut short off by the cold wave of the 21st. We had a skiff of snow (a sight never before witnessed here at this season of the year), on

the night of the 21st. The bees were housed for 3 days. White clover is wasting. I have been feeding a swarm that issued just before the present cold, rainy, gloomy spell. The prospects look better to-day (23d). I notice that the three dismal, cold, rainy days just past, have afflicted some of my nursing nuclei with dysentery. The weather has been unfavorable to queen rearing—too changeable.

G. W. DEMAREE.
Christianburg, Ky., May 23, 1883.

Phacelia for Honey.

I send you a bee plant for name. It is an early bloomer, and the bees swarm on it. The plant is a native of this country.

E. E. EWING.
Highlands, N. C., May 8, 1883.

[This is *Phacelia pusilla*, a plant with no other common name than that of the genus or first part of the scientific name here given. It is a peculiarly Southern species, though the genus is well represented throughout the United States, and are all important honey producers. Most of the members of the family (Waterleaf Family), grow in shady places, but this and a few others thrive in the open sunshine on prairies, etc. They often clothe the banks of railroads, etc., on particular soils, and this, no doubt, might give a hint as to their cultivation, should this be desirable. The flowers are almost wholly dependent on honey-loving insects—especially bees—for fertilization, as the stamens and pistils of the same flower mature at a different time. The attractions for the bees are, however, such, that there is little loss in seed production on this account; the pollen is abundant, and the nectar copious and easy of access.—T. J. BURRILL.
Champaign, Ill.]

Cold, Cold, Cold.

We have not had 5 days so far this year, warm enough to open the bee hives without danger of chilling the brood, of which there is but little. It freezes nearly every night. On the morning of the 14th, ice was found $\frac{1}{2}$ inch thick. Bees are getting poor in numbers and short of stores.

G. M. DOOLITTLE.
Borodino, N. Y., May 17, 1883.

The Spring in Texas.

The spring thus far in Texas has been cold and backward. We are three or four weeks later than usual. Our spring crop of honey will be short. On the prairies, the bees, as yet, have gathered but little honey. I have moved my bees from Shreveport, to Arlington, west of Dallas, to take advantage of the horsemint. This is the great honey-producing plant of Texas. My bees wintered well, as they always do when they have plenty of honey. Without an unusual sum-

mer, and fall, we will not have so good a honey season as the last. Our State Bee-Keepers' Convention met at McKinney, on the 16th of April; we had a good turnout, and considerable enthusiasm. The business of bee-culture is largely on the increase in Texas, and bids fair to be, in a short time, one of our largest industries. We, of the South, hope that the bee papers will have nothing more about wintering bees in them, this year. This is a subject that does not interest us; in fact, we do not read the articles on that subject. We would like, at least for the summer, to have the periodicals filled up with matter relating to the general interest of bee-culture. I am glad you, Mr. Editor, are disposed to exclude personal matter, and personal censure from the BEE JOURNAL.

W. R. MARSHALL.
Marshall, Texas, May 18, 1883.

Still Snowing.

Byron said, "The moon is up, and yet it isn't night." We can say, "It snows yet, but still it is not winter." Bees were never so weak and poor in stores at this date in my apiary. I have lost 125 out of 350, and the loss will amount to 150, ere warm weather arrives. As the law of supply and demand governing prices has not yet entirely deserted apiculture, every dead colony enhances the value of all the living. All bloom is 2 weeks behind time.

JAMES HEDDON.
Dowagiac, Mich., May 22, 1883.

Prospect Good.

The bees are doing well, in spite of the weather. We had a white frost last night, and the night before, and a big swarm of bees to-day. White and alsike clovers are coming on finely, and the prospects are good for a large honey crop.

J. V. CALDWELL.
Cambridge, Ill., May 23, 1883.

Cyprians Ahead.

Last fall I had 55 colonies (5 being weak ones); and, out of the 55, 1 lost 11; one starved, 3 swarmed out this spring, and seven died with the dysentery. The Syrians and Cyprians wintered the best of all, with few exceptions, and the Cyprians are ahead of all, for they have more brood and honey than any of the rest; the outside combs are filled up with new honey, and sealed up two-thirds of the way down, and last Saturday (19th) one of them swarmed. How is that, for Cyprians, for a wet and cold spring? I think the Cyprians are the hardest race of bees in America. I handle my Cyprians without gloves or veil, and do not get stung very often either. I think the man that is disposing of his Cyprians is fooling his time away. The snow is 2 inches deep this morning, and is melting fast, and it is raining now. This has been the worst spring for bees I ever saw, and it does not look very favorable this morning. I do not think my Cyprians will swarm to-day, and yet I expect them to swarm as soon as it gets warm again.

L. A. LOWMASTER.
Belle Vernon, O., May 22, 1883.

A Wrong Righted.

In my article, on page 252, headed, "That 'Three-Ring' Fancy," in trying to right myself, perhaps I wronged Mr. Heddon; if so, I apologize, for I had no such intention; far from it. As I am a believer in short sermons, perhaps I did not make things clear. Some may think I was trying to cast a reflection on Mr. Heddon's way of breeding, but I had no such thought. Honestly, I believe his way of crossing the dark leather-colored Italian with the brown German bee, will, in time, bring forth the true *Apis-Americana*—the "bread and butter" bees.

W. H. SHIRLEY.

Glenwood, Mich.

A Snow Storm in Indiana.

We have had the worse snow storm ever known for this time of year, in Indiana. It commenced with a cold rain, and yesterday, about 10 o'clock, it turned to snow, and snowed until night; although it melted very fast, there was about 2 inches of snow on the roofs, boards, etc. It snowed more last night, and fruit trees are bent to the ground, and the timber is mourning under its heavy burden. I think there has fallen quite one foot of snow, since yesterday morning. Bees were doing extra well; their brood-chambers are full of brood and honey, and some were storing honey in the boxes. White clover is beginning to bloom, and is as plenty as I ever saw it, and everything looked favorable for a good harvest, but it looks dismal this morning.

A. FRAZER.

Bloomingsport, Ind., May 22, 1883.

In Good Spirits.

Bee-keepers are in good spirits—having prospects of a rich, white clover harvest. Bees are in fine condition, and are gathering honey rapidly from the clover.

N. P. ALLEN.

Smith's Grove, Ky., May 23, 1883.

Some Corrections.

DEAR JOURNAL:—In an article written by me on the 17th of March, and published on the 16th of May, on pages 248 and 249, you make me say: "I purchased 2 colonies of bees in December, 1883." I meant to have said 1863. And on page 249, in my 3d rule, "To cool off the cellar, when the weather outside is colder than 40°, let in as little air as will keep the bees alive, and keep ice in the pipe." I meant to have said: "To cool off the cellar, when the weather outside is below 40°, let in more air; and when the weather outside is above 40°, let in as little air as will keep the bees alive, and keep ice in the pipe." And in the 1st rule, same page, the "have them," etc., should be, having them, etc., making the cushioning and otherwise keeping them warm, one of the requisite conditions to late breeding. If you will kindly make this correction, my meaning will be better understood.

H. V. TRAIN.

Mauston, Wis., May 19, 1883.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL.
Monday, 10 A. M., May 28, 1883.

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.**CHICAGO.**

HONEY—The nominal price of extracted is 7c. for dark and 9c. for light—here. The supply is abundant and sales are slow.

BEESWAX—None in the market.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The market for extracted honey is lively, and the demand exceeds the arrivals. Our stock is small and we are in danger of having sold out every day. We pay 7@10c. for good honey on arrival, the latter price for choice clover. There is a small demand for comb honey, and prices nominal.

BEESWAX—Arrivals of beeswax are plentiful. We pay 35c. for a good article on arrival.

CHAS. F. MUTH.

Quotations of Commission Merchants.**CHICAGO.**

HONEY—The demand is light and it is not now probable that all of the comb honey can be sold before a new crop comes. Prices are very irregular and generally low: 15@16c. for white, and dark unsalable. Extracted, very little trade is being done in it. 7@9c. is about the market.

BEESWAX—35@36c.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Stocks and the demand are both light. More or less difficulty would be experienced in filling a large order for a straight lot.

White comb, 14@17c.; dark to good, 11@13c.; extracted, choice to extra white, 8@9@9½c.; dark and candied, 5@7½c.

BEESWAX—Wholesale, 27@28c.

STEAKS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Dull; light jobbing sales only. Comb at 10@14c.—Strained and extracted at 7@7½c.

BEESWAX—Sold lightly at 32@34c.

W. T. ANDERSON & Co., 117 N. Main Street.

CLEVELAND.

HONEY—Stocks of honey are running low with us. 1-lb. sections are all sold and there is a very light inquiry for such; would probably sell at 18@20c. 2-lb. sections are not in demand, and no sales to quote, asking 17@18c. Extracted no sale at 9@10c.

BEESWAX—Not offering.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—Our market is fairly active. We quote: ½ lb. sections at 39c.; 1-lb. sections, 22@25c.; 2-lb. sections, 20@22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.

BEESWAX—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatbam Street.

A \$20.00 Bible Reward.

The publishers of *Rutledge's Monthly* offer twelve valuable rewards in their *Monthly* for June, among which is the following:

We will give \$20.00 in gold to the person telling us which is the shortest verse in the Old Testament Scriptures by June 10th, 1883. Should two or more correct answers be received, the reward will be divided. The money will be forwarded to the winner June 15th, 1883. Persons trying for the reward must send 20 cents in silver (no postage stamps taken) with their answer, for which they will receive the *July Monthly*, in which the name and address of the winner of the reward and the correct answer will be published, and in which several more valuable rewards will be offered. Address, RUTLEDGE PUBLISHING COMPANY, Easton, Penna.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
" 100 colonies (220 pages)..... 1 50
" 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

BOOK CLUBBING LIST.

We will supply the *American Bee Journal* one year, and any of the following Books, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

Price of both. Club

The *Monthly Bee Journal* and any of the above, \$1 less than the figures in the last column.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of *Bees and Honey*, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the *Weekly BEE JOURNAL* for one year.

To get any of the above premiums for the *Monthly BEE JOURNAL* send double the number of subscribers, and the same amount of money.

Special Notice.—We will, hereafter, supply the *Weekly BEE JOURNAL* for one year, and the seventh edition of Prof. Cook's Manual of the Apiary, bound in fine cloth, for \$2.75, or the *Monthly Bee Journal* and the Manual in cloth for \$1.75. As this offer will soon be withdrawn, those who desire it should send for the book at once.

Emerson Binders—made especially for the *BEE JOURNAL*, are lettered in gold on the back, and make a very convenient way of preserving the *BEE JOURNAL* as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Bingham Smoker Corner.

Large Smokers need wide shields. Bingham's have them, and springs that do not rust and break, and bellows that sparks and smoke do not enter. The Conqueror has all improvements made to date, and a 3x7 inch stove, and 5x7 inch bellows. Sent post-paid for \$1.75. Address,

BINGHAM & HETHERINGTON,
Abronja, Mich.

All Excelling. — Messrs. Bingham & Hetherington, Dear Sirs:—I am now selling your Smokers almost exclusively. You are excelling yourselves in smokers all the time.

Respectfully, J. G. TAYLOR.
Austin, Texas, May 10, 1883.

Cyprians Conquered.

All summer long it has been "which and totter" with me and the Cyprian colony of bees I have—but at last I am "boss." Bingham's "Conqueror Smoker" did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham.

G. M. DOOLITTLE.
Borodino, N. Y., Aug. 15, 1882.

During the following three months, Bingham Smokers will be sent post-paid, per mail, on receipt of the following prices:

The "Doctor" (wide shield)—3 1/4 in. fire tube, \$2.00
The Conqueror (wide shield)—3 in. fire tube, 1.75
Large (wide shield)—2 1/4 in. fire tube, 1.50
Extra (wide shield)—2 in. fire tube, 1.25
Plain (wide shield)—2 in. fire tube, 1.00
Little Wonder (narrow shield)—1 3/4 in. fire tube, .65
Bingham & Hetherington Uncauping Knife.. 1.15

With thanks for letters of encouragement, and the absence of complaining ones, we tender to our thirty-five thousand patrons our best wishes.
Very Respectfully Yours,

BINGHAM & HETHERINGTON.
Abronja, Mich., June 1, 1883.

Foul Brood Pamphlet.—Wishing to be relieved of sending out my pamphlet on Foul Brood, I have made arrangements with Mr. T. G. Newman to supply them to the bee-keeping fraternity desiring them. Price 25c.

A. R. KOINKE.
Youngstown, O., April 25, 1883.

SPLENDID QUEENS, by Mail, \$1 each; 6 for \$5.50. F. L. WRIGHT, Plainfield, Mich.
22A11

NO MORE BEES TO SELL.—I cannot fill any more orders for bees. I have already sold myself short. W. H. BALCH, ORAN, N. Y.
22A11

QUEENS!

During June and July, I shall be prepared to furnish the CHOICEST OF QUEENS, both tested and untested, from two different strains. 1. From my new strain, viz: a cross between the Brown, German, and dark leather most red Italian. 2. Pure Italians reared from imported mothers. With my hives of all worker combs, using drone comb where I desire it only, isolated from other apiaries, I have the best of opportunities to control the mating of my Queens. I rear Queens under the warm Italian only, and upon the true plan of getting the best and most vigorous stock. All orders filled in turn, and it is useless to hurry us.

PRICES:
Tested Queens (all selected) each.....\$ 3.00
Untested before July 1, each.....1.50
Untested after July 1, each.....1.00
These are bottom prices in any quantity. Send for descriptive Catalogue to
JAMES HEDDON, Dowagiac, Mich.

THE HANDY BOOK.

Read the opinion of one of the most eminent writers on bee matters:

Bound Brook, N. J., May 4, 1883.
FRIEND ALLEY:—Handy Book received. I am happy to say that I consider that it tells more on the vital subjects of rearing Queens and managing bees so as to take honey, than any book now before the public. It seems to be filled with just those things which practical men find out about their business in a lifetime of work, but which they generally don't tell the dear public.

J. HASEBROUCK.
The HANDY BOOK has received from those most competent to judge of its value, more praise than any book now in print. Send for our Circular and get their opinions.

HENRY ALLEY, Wenham, Mass.

21A11

A NEW BEE BOOK!

BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS C. NEWMAN,
Editor of the *Weekly Bee Journal*.

925 West Madison Street, Chicago, Ill.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most money in its best and most attractive condition.

Appreciative Notices.

A neat and abundantly illustrated hand-book of apiculture.—*American Agriculturist*, N. Y.
Its chapter on marketing honey is worth many times its cost.—*Citizen*, Pulaski, Tenn.

Contains all the information needed to make bee-culture successful.—*Exale*, Union City, Ind.

Just such a work as should be in the hands of every beginner with bees.—*News*, Keltshburg, Ill.

Valuable for all who are interested in the care and management of bees.—*Dem.*, Allegan, Mich.

Engravings are fine. Gotten up in the best style, and is cheap at the price.—*Farmer*, Cleveland, O.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—*Daily Republican*, Utica, N. Y.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—*Sentinel*, Rome, N. Y.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—*Chicago Herald*.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—*Daily Times*, San Bernardino, Cal.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form.

It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—*Farmer*, Lancaster, Pa.

PRICE—Bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

THOMAS C. NEWMAN,

925 W. Madison St., Chicago, Ill.

OPIUM Morphine Habit Cured in 10 to 20 days. No pay until cured.

J. L. Stephens, M. D., Lebanon, O.

18A11

PURE ITALIAN BEES AND QUEENS,

Tested and untested Queens, nuclei in Langstroth's frames, tall colonies, queens by the half dozen, bees by the pound. Send for prices and particulars.

A. B. MILLER & SON,
Wakarusa, Elkhart Co., Ind.

44A11

ELECTROTYPES

Of Engravings used in the *Bee Journal* for sale at 25 cents per square inch—no single cut sold for less than 50c.
THOMAS C. NEWMAN,

CHICAGO, ILL., JUNE 6, 1883.

No. 23.

THE AMERICAN
BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

The Clouds of Adversity Departing.

The present Spring, if it deserves that name, has been one of severe trial for the bee-keeper. Winter, as an unwelcome guest, lingered in the lap of Spring so long that his presence became irksome and disgusting. We have the following wail from Mr. Heddon:

Still Snowing.

Byron said, "The moon is up, and yet it isn't night." We can say, "It snows yet, but still it is not winter." Bees were never so weak and poor in stores at this date in my apiary. I have lost 125 out of 350, and the loss will amount to 150, ere warm weather arrives. As the law of supply and demand governing prices has not yet entirely deserted apiculture, every dead colony enhances the value of all the living. All bloom is 2 weeks behind time.

JAMES HEDDON.

Dowagiac, Mich., May 22, 1883.

And Mr. Doolittle wrapped himself in his overcoat and sighed:

Cold, Cold, Cold.

We have not had 5 days so far this year, warm enough to open the bee hives without danger of chilling the brood, of which there is but little. It freezes nearly every night. On the morning of the 14th, ice was found $\frac{1}{2}$ inch thick. Bees are getting poor in numbers and short of stores.

G. M. DOOLITTLE.

Borodino, N. Y., May 17, 1883.

While Mr. Demaree records the fact of having

A Cold Wave in Kentucky.

Notwithstanding the weather here has been very changeable, the season so far has not been altogether unfavorable. My bees have built up rapidly, and have done well on fruit bloom, dandelion, etc. Locust opened on the 13th inst., and gave a deluge of nectar till cut short off by the cold

wave of the 21st. We had a skiff of snow (a sight never before witnessed here at this season of the year), on the night of the 21st. The bees were housed for 3 days. White clover is wasting. I have been feeding a swarm that issued just before the present cold, rainy, gloomy spell. The prospects look better to-day (23d). I notice that the three dismal, cold, rainy days just past, have afflicted some of my nursing nuclei with dysentery. The weather has been unfavorable to queen rearing—too changeable.

G. W. DEMAREE.

Christianburg, Ky., May 23, 1883.

And Mr. Frazer is not at all pleased with

A Snow Storm in Indiana.

We have had the worse snow storm ever known for this time of year, in Indiana. It commenced with a cold rain, and yesterday, about 10 o'clock, it turned to snow, and snowed until night; although it melted very fast, there was about 2 inches of snow on the roofs, boards, etc. It snowed more last night, and fruit trees are bent to the ground, and the timber is mourning under its heavy burden. I think there has fallen quite one foot of snow, since yesterday morning. Bees were doing extra well; their brood-chambers are full of brood and honey, and some were storing honey in the boxes. White clover is beginning to bloom, and is as plenty as I ever saw it, and everything looked favorable for a good harvest, but it looks dismal this morning.

A. FRAZER.

Bloomingsport, Ind., May 22, 1883.

Mr. G. W. Ashby grows despondent over his

Sad Case of Spring Dwindling.

I send the discouraging news of my sad disappointment in my bees. I doted upon my 66 colonies which I had in the fall of 1882. Now I have 56; they wintered well enough, but dwindled away in the spring, till my loss is ten; and nearly one-half of the others are to-day nothing more than nuclei. If I unite them, or wait until they build up, I shall get no honey this season, from a part of them. We are now in the locust, poplar and white clover bloom, etc. The bees all have a good quantity of brood. It has been a very bad spring here; it was too cold during peach and apple bloom. On May 15, we had almost a blizzard. We had to wrap up as in

winter. Now it is too windy and dry; the bees cannot stick to the locust blossoms; they are blown and tossed about in every direction, and many are lost in the pond. It is awful to see my pets have such a time. I fondly anticipated a glorious harvest, this season, of several thousand pounds of honey. I ordered a lot of bee supplies and foundation to aid them, but all my fond hopes are blasted. Not a swarm yet, and but few colonies look likely to make a surplus. I have one colony in the Cunningham hive, which seems to outstrip all the others. They are at work in four boxes of 5 pound weight; more than one-half built out, and partly filled with honey. The others are in the Langstroth hive. If you ever saw any one have the blues, I am the one. I have quit looking after my farming interest, and gone wild on the bee, that wonderful insect. I will have to give up, and keep one or two to study their mysterious ways. My whole thoughts were centered on the bee, but, alas, I must look after some other business for a livelihood. I got all kinds of seeds to sow for my bees; last year I had a fine lot of sweet clover. My bees went wild over it; this year there are only about 100 plants to the acre, all told. Alsike is in tolerable condition; Simpson honey plant, fine; Rocky Mountain bee plant, none; spider plant, none. My grief is past endurance.

G. W. ASHBY.

Valley Station, Ky., May 17, 1883.

Judge Andrews gives a cheerless account of

The Spring in Texas.

There never has been such a spring for bees in South Texas before; my bees have not swarmed as much up to this date as they did last year by the 27th of March. They have not increased 3 per cent. yet, and the prospect for more than 25 per cent. is poor; but I confess that we are sailing in "unknown waters."

W. H. ANDREWS.

McKinney, Texas, May 27, 1883.

And Dr. H. M. Williams reports discouragingly that it is

Still Cold in Georgia.

We are having the latest spring here I have known in 20 years. For the last three mornings the thermometer stood at 42°, and we have had considerable frost. Bees have done nothing in the way of storing honey in the upper story. My bees are

swarming some, and I am hiving them on full combs, where my bees died in the winter. When I put a swarm in a hive full of empty combs, they go back and rob the old hive, so I have to move the old one. I expect they rob the old one because the honey flow is small. I have 60 colonies; some pure Italian, some hybrid, and I am satisfied my mixed bees, with the pure blacks and Italians are the best bees I have, for honey; though not so easy handled. I am always glad when the BEE JOURNAL comes; I could not do without it.

H. M. WILLIAMS, M. D.
Bowden, Ga., May 24, 1883.

These letters are anything but encouraging; truly, in the language of Thomas Paine, "These are the times that try men's souls." We do not wonder why some may become discouraged, as they view the untenanted hives and soiled combs which are left, as the sequel to their cherished hopes for the future. However, none should be too hasty in passing judgment. With the hives and combs already provided, more than one-half the original investment is saved, and with a propitious season for the present, our losses will be made good with a credit in our favor on the balance sheet. We cannot expect bee-keeping to be unvaryingly prosperous, any more than any other special branch of industry which is dependent upon natural causes, but we can, with forethought, industry and systematic perseverance, make it as reliable as any other.

Were it only the lesser bee-keepers, or the novices, who had suffered losses, it might, perhaps, be attributed to ignorance or negligence; but when we take into account the losses by specialists and scientific bee-keepers, we cannot but look upon such a charge as an insult to intelligence.

The fruit-grower expects frequent failures in his crops, and is thankful that his trees survive without injury; the farmer's wheat winter-kills, when he plows up the ground in the spring and plants anew in corn or something else, and replants if frost kills that; the stock-raiser who loses part of his flock, gives the remainder better attention, and patiently toils two or three years to repair his losses; the merchant has his seasons of loss, but with renewed push and activity makes up for the dull times when the "good time coming" has arrived; and the energetic bee-keeper, although many bright dreams may have vanished, will not despond, but without taking time to count the untenanted hives, begins immediately to estimate the

number he can refill, working with a will to retrieve his losses; and while keeping time with the musical hum of his bees, in the "Sweet by-and-by" will reap a more than commensurate recompense for his vexations and disappointments.

As we write this the air has again become warm, the sun shines out as cheerfully as it ever shone on a summer's day. The robin's cheerful piping, and the bluebird's merry song can be heard in the early morning, as the golden sunshine tips the hill-tops, and the hills and valleys are arrayed in gorgeous robes of emerald green.

The trees, plants and shrubs have commenced to bloom here in the North, and soon the heavy basswood will enrich the hives, making them to overflow with the rich nectar. Let all, therefore, take courage and prepare for a vigorous season's work—the sunshine already succeeds the storm, and chases the gloom away. Be cheerful and hopeful—there is no time to lose. Nature now awakens to life; the far-stretching fields clothed in emerald green, the lawns and lanes with their grassy carpets, the air laden with the sweet perfume of the blossoms in garden and orchard, the trees in forest and grove animated with the feathered songsters whose little lives seem an incarnation of happy melody—all these combine to help us forget the dreary hours of the past, and with keener zest enjoy the future.

"Into all lives rain must fall,
Over all lands the storm must beat,
But when the pain and the storm are o'er
The after-sunshine is twice as sweet.
Through every straight we have found a road,
In every grief we have found a song,
We have to bear, and have had to wait,
But think how well we have got along."

☞ We have received from Mr. Wm. Sims, Secretary of the Kansas State Board of Agriculture, at Topeka, a pamphlet entitled "Kansas, its Resources and Capabilities," which is being printed in the English, German, Swedish, and Danish languages, for gratuitous distribution, and will be sent to any one upon application, or will be mailed to any address furnished, either in this country or Europe, the person sending address to indicate the language desired. It contains a map of the State, and several views of farms, cattle, ranches, etc., and is full of useful information concerning that State.

☞ Mr. Alley's new book on Queen Rearing will hereafter cost \$1.25

Honey and Bee Show in Canada.

Mr. A. Robertson, of Carlisle, in the *Canadian Farmer* gives the following list of prizes offered in the Honey and Bee Department of the Hamilton Central Fair:

As the directors of Hamilton's Central Fair had a meeting on April 24, I am now able to present our prize list. I feel like giving three cheers to the directors, for the way they used us; they gave us nearly everything we asked for. Last year we were mixed up with the *fruit*, such as turnips and cabbages, and the prizes altogether amounted to about \$20. This year we are to have a class by ourselves, and they are offering prizes to the amount of \$70. They also allow us to appoint our judges, and we will endeavor to get practical bee men, who each use a different size frame and hive.

Prizes offered by the Central Fair Association:

	1st.	2d.
For best Comb Honey, not less than 10 pounds.....	\$5.00	\$3.00
For Best Extracted, not less than 10 lbs.	5.00	3.00
For Best display of Comb Honey.....	8.00	4.00
For Best display of Extracted.....	8.00	4.00
For Best and largest display of both kinds.....	10.00	5.00
For Best Exhibition and management of Bees.....	10.00	5.00
For Best Hive for Comb Honey.....	4.00	2.00
For Best Hive for Extracted Honey.....	4.00	2.00
For Best Hive for all purposes.....	Medal and Diploma	

The following are by our Bee Association and Specials:

Best display of Apianian Supplies.....\$10.00 \$5.00

Specials given by D. A. Jones, Beeton, Ont.:

Best display of Extracted Honey, put up in the most pleasing and marketable shape, best imported Holy Land Queen, valued at.....	\$15.00
Best display of Comb Honey, in the best marketable shape, best imported Cyprian Queen, valued at.....	\$10.00

In both of the above classes, exhibitor must be producer.

Special by Green & Robertson, Carlisle, Ont.:

Best Bee Hive for all purposes, Chaff Hive complete, for Comb Honey, valued.....	\$5.00
Root's Simplicity Hive complete, for Extracted Honey.....	2.00

Special by J. M. Knowles, President of the Association:

Best Observatory Hive.....\$5.00

Special by *Canadian Farmer*:

Best display of Wax, <i>Canadian Farmer</i> for one year.....	1.00
Best Honey Crate, <i>Canadian Farmer</i> for one year.....	1.00

☞ Ants are sometimes troublesome in an apiary. They can be destroyed by sprinkling salt around the hives and in the ant-hills.

☞ Renewals may be made at any time; but all papers are stopped at the expiration of the time paid for, unless requested to be continued.

☞ Postage stamps, of one, two or three cent denomination, accepted for fractional parts of a dollar; but money is preferred, for larger amounts.

How to Foretell the Weather.

A. J. DeVoe, of Hackensack, N. J., sends to the Farmers' Club of the American Institute, the following nine rules by which, it is said, a person in any part of the Northern Hemisphere (north of 15° of latitude) can form an accurate opinion of the wind and weather for a hundred miles around him:

1. When the temperature falls suddenly, there is a storm forming south of you.
2. When the temperature rises suddenly, there is a storm forming north of you.
3. Wind always blows from the region of fair weather toward a region where the storm is forming.
4. Cirrus clouds always move from a region where a storm is in progress toward a region of fair weather.
5. Cumulus clouds always move toward a region where a storm is raging.
6. When cirrus clouds are moving rapidly from the north or northwest, there will be a cold rain storm on the morrow; if it be winter, there will be a snow storm.
7. The wind blows in a circle around a storm, and when it blows from the north, the heaviest rain is east of you; from the south, the heaviest rain is west; from the east, the heaviest rain is south; from the west, the heaviest rain is north of you.
8. The wind never blows unless rain or snow is falling within 1,000 miles of you.
9. Whenever a heavy white frost occurs, a storm is forming within 1,000 miles north or northwest of you.

A few Seasonable Hints.

As there has, during this spring, been so much cool and wet weather, the bees are suffering for food. Mr. Oatman, who was in our office a few days since, says he is systematically feeding his bees every day in order to keep them strong in numbers, and ready for the honey harvest. Mrs. L. Harrison, in the *Prairie Farmer*, remarks as follows:

Those who are desirous of increasing their colonies, should feed liberally, whenever the honey flow fails, either by reason of cool or rainy weather, so that brood-rearing will not be retarded. Large quantities of stores are consumed in brood-rearing, as a bee eats more in a larvæ state, than during the remainder of its life. New swarms sometimes, perish during long continued rainy weather, by starvation. It is good management to feed during intervals of honey-gathering, as the queen lays, not according to the stores on hand, but in ratio to her income.

Some colonies have too much honey, so that the queen has not room enough to lay; when this is the case, it should be removed, and may be ex-

changed for empty comb, from a less provident stock, and both be benefited. Diluted honey, or syrup made of either brown or white sugar, can be fed almost any way, at this season of the year. Great care should be exercised, lest robbing is induced, by dropping the feed around the hives. The feed should be thin, and the vessels holding it should contain cut straw or little floats to prevent the bees drowning, or a piece of thin cloth can be spread over the surface. Where two story hives are used, the feed can be placed in the upper one, and a small aperture made to allow the bees to come up from below; or if a division-board is used, it can be placed back of it. Anyway that does not admit bees from the outside, or let the warmth from the cluster escape.

Bee-Keeping in Florida.

Mr. J. M. Lisenby, of Cedar Key, writes to the *Florida Journal* as follows concerning bee-keeping:

As the interest in Florida and its various resources are attracting considerable attention, I will try to give some facts in regard to bee-keeping—an industry that can be made successful in quite a large portion of the State. It is true that a great deal of the interior—especially the high pine lands—is not adapted to bee-culture, while the Atlantic coast, south of St. Augustine, and the Gulf coast, south of Cedar Key, certainly are rich honey-producing sections.

In the best bee pastures of the State the season for storing surplus honey only lasts about two months; but in this short time they will store from 100 to 150 pounds per hive, and the remainder of the year they will gather enough for their support.

At Cedar Key the bees commence breeding in January, and continue to breed until November. They usually commence to swarm in March, and continue until about the first of June, when the work of storing surplus honey begins.

The mangrove is the principal honey-producing plant, and the honey gathered from it cannot be excelled in appearance, even by the white clover honey of Vermont, and the superiority of the mangrove over other honey-producing plants, is that, growing as it does in the marshes, it is never affected by the floods or drouth.

The honey produced from the palmetto is also of good appearance and flavor, yet it is not so reliable as that from the mangrove.

I have never been in any country where I had as little trouble to manage bees as this. They are never troubled by worms or bee-moths, if they are kept in anything like good condition.

Mr. Joseph D. Enas, Napa, Cal., has issued a six-paged circular and price list for Queens and Supplies for the Pacific Coast.

Honey Production in Canada.

I enclose an item of bee news, clipped from the *Montreal Witness* of May 9, containing an inquiry and reply by D. A. Jones, of Beeton, Ont., who edits the bee department of that paper. I think Mr. Jones' reply does American honey producers an injustice. I have lived in Canada for 40 years, and my experience and observation have been the very reverse. What is your opinion?

Marlette, Mich. WM. SHIER.

In answer to the inquiry, Mr. Jones makes the following very extravagant assertions:

I strongly I advise your remaining in Ontario. You will find that the people of Canada are better educated to the use of honey—and especially extracted honey, which is more profitable than comb. Packages for putting up honey are cheaper in Canada than the United States, and we seem to be far ahead of our neighbors in the style of putting them up. The labels which are being used by the United States' dealers now so extensively are made here in Canada, and the duty they pay is high. Above all these considerations there are localities in Canada which are superior to any in the United States. For large yields of honey the West is second to no country in the world, and our bee-keepers are at the present time more than equal in the race as regards supremacy for fine bee-keeping. Many of the new devices and improvements emanate from Canada's bee-keepers.

Many persons think their own bees, hives, utensils and locations are the best, and, perhaps, this individual and local pride dictated the reply of Mr. Jones. Of course no one on this side of the boundary will agree with him.

Honey for the Children.—The *Farmers' Review* thus comments approvingly on a late editorial in the BEE JOURNAL:

Editor Newman, of the BEE JOURNAL, wisely suggests that those parents who feed their children on candies and syrups, because they want something sweet, to the great injury of the children, would find their children growing healthy and happy too, if given good honey instead of candies that are so fearfully adulterated.

The number of the *Bulletin D' Apiculture pour la Suisse Romande*, for May, has a full-page illustration of Mr. Chas. Dadant, of Hamilton, Ill. It is a lithograph, and is quite natural.

The *American Apiculturist* is the title of a new monthly just started by S. M. Locke, at Salem, Mass. It contains 32 pages, and makes a very creditable appearance.

CORRESPONDENCE

For the American Bee Journal.

Systematic Breeding, etc.

G. W. DEMAREE.

On page 236, present volume of the BEE JOURNAL, Mr. Heddon approaches the old subject, "Best bees, etc.," with apology and apparent trepidation; but still he approaches the subject and comes prophesying.

The subject is "unpleasant" just now, but there are "millions in it." "Three-fourths" of the bees sold hereafter will be hap-hazard-hybrids. I only take the liberty to put it in plain English. I mean nothing but good to the cause of apiculture. I write this article not because it is pleasant or "unpleasant" to me, but because I wish to raise the standard of systematic breeding rather than to trail it in the dirt, and rather because as a breeder, I do not seek to be released from responsibility as to the character of my queens and bees.

I protest against the present tendency—mercenary tendency—to lower the standard of bee-breeding below the standards adopted and approved by all breeders of domesticated animals. I can see no reason why bee-breeding should not be entitled to as much dignity as a business as other like occupations.

"Bees for business" may be suggestive to some people of the hasty-made dollar, but to me it sounds like a clap-net, cheap advertisement. Let us suppose that a prominent breeder of farm stock should breed his "breeding stock" for "business," ignoring pedigree and purity of blood. Could any one doubt the result of such a course? He would soon find himself "ignored" as a breeder, and justly too, because the very necessity of the case demands, that, in breeding stock, some distinguishing features must be adopted as a test of the purity of the stock, and as a guarantee of good faith on the part of the breeder. So important is this matter considered by the stock interest in Kentucky, that the Legislative department of the State have enacted statutory laws to punish fraudulent, and protect honest breeders.

A prominent stock breeder has suggested that the reason why the mule has been a perpetual success is, because he is a "mule," and, therefore, cannot be deteriorated by unlimited crossing by those who are ignorant of the laws of scientific breeding.

It has occurred to me that it would be better for the future good of apiculture if the hybrid bee (the word "hybrid" in bee lore means a cross between the Italian and German races) was, in fact, a mule, in which case they might justly and properly be called "bees for business." The first cross between the two races make good business workers, but they are utterly unfit for breeding stock.

I insist that every honorable breeder of bees should be able to give a description of his stock sufficiently comprehensive to enable any one to identify them, and distinguish them from other races and strains of bees.

The transparent attempts, of late, to render ridiculous the chief features by which the Italian or yellow race of bees is most easily identified, is the severest blow of all to scientific breeding. All who have cared to read my articles on the subject of the three-band test, are aware of what my views are concerning that matter, and I need not consume time and space to go over the grounds again; but I do say that there is no such a thing as Italian bees without the yellow bands, and those who sneer at "bands" and "stripes" simply sneer at the Italian bee. I have no controversy with those who prefer native or mixed bees to the Italian, but they should stand to their position.

Let us look for a moment at this matter of "bands" and "stripes." Most breeders are able to describe the stock sold by them so clearly that they can be identified as a distinct race or variety. Some insure their tested queens to produce workers that will show the three-bands, if filled with honey and placed in a window. Some insure them to show the bands while standing on the combs; others sell "golden" Italians. If these last know what a golden Italian is, the workers must show the beautiful golden plumage in addition to the bands. Pure Albinos must have the white or silver bands, which consist of plumage, in addition to the regular bands.

Other distinguishing features may be named. My favorite strain of bees may be described as slender in form, the second band conspicuously broad, while the corslet and posterior bands are rather narrow, but finely cut and distinct. As a general rule they have but little plumage on their bodies, and that little is of a light, but not of a golden hue, as is the case with the golden variety.

I would describe them generally as slender, orange-banded bees. If there are any bees in the country that can beat them as honey-gatherers, I have a reasonable number of dollars which I would like to exchange for a few colonies of them. It will be seen that the several strains of bees described above may be identified wherever seen by the description given.

Now, apply the test to the "business bees" about which we have heard so much of late. It will be admitted that Mr. Heddon is good authority on the subject, and if there is a man living who can give an intelligent description of the "business bee," Mr. H. is the man to do it. Well, I have been reading his articles on "Business get-there bees" in nearly all the bee papers for two years past, and the most that I can make of it is, they are "larger" than some "shorter" bees are, and "darker" than some "lighter" bees are, and may or may not have "stripes." The description is wonderfully accommo-

dating. No one, I presume, but Mr. Heddon, can identify them.

Texas State Bee-Keepers' Convention

The fifth annual meeting of the State Bee-keepers' Association was held in the apiary of Judge W. H. Andrews, at McKinney, Texas, on April 17 and 18, 1883.

After the routine business was done, the president addressed the meeting upon the subject of "Conventions." The address, though well-timed and interesting, but we have thought best not to send for publication, as we fear we may overtax the space of our valuable JOURNAL.

Dr. W. K. Marshall, of Marshall, then read his admirable essay on the "Different races of bees." [As soon as I am furnished a copy I will forward for publication.—Sec.]

The question was asked, "Are Cyprians remarkable as workers?" to which Dr. Marshall replied: "They are swift on the wing, and as industrious as any bees he ever handled, and gave as good results."

In answer to a question as to the temper of the Cyprians, the Doctor said they are cross, very easily angered, and when aroused, would sting everything on the yard, from chicken to king; and would not "down," but they were not a ghost.

Judge Andrews said he could not speak from a satisfactory trial, having handled but 3 colonies, which were enough to do him "the rest of the way."

It was asked if it is true that their queens are so wonderfully prolific as they are said to be?

Dr. Marshall said they are great breeders, and that he had thought they had too much at certain seasons. Judge Andrews said that Dr. Dzierzzone says they breed so late in the fall that in bad honey years they often come out rich in bees, but poor in honey.

It was asked of Dr. Marshall, what are dark Italians? He replied that he regarded them impure bees, whether home-bred or imported.

E. H. West, of Tarrant county, asked Judge Andrews if he thought Italian bees swarmed more than blacks? He replied that he could see no difference as to that.

Are Italians better honey gatherers than the blacks? Dr. Marshall said he could not say that they were, but that they possessed some valuable traits peculiar to their race. Judge Andrews said he did not know what those traits are, but that he claimed but two points for the Italian over the blacks and all others; those are beauty, most exquisite, and amiability; that he could manipulate two colonies of Italians to one of the other races; he says the queens of the other yellow races are not near so beautiful as those of the Italians.

Judge Andrews was asked if he thought that hybrids are more irascible than blacks, as taught in our leading books on bee-culture? And

he replied, that his bees became good-mannered in proportion to their Italian blood, and *vice versa*.

It was asked, "Can we, by the comingling of races and careful selection, reach the 'coming bee'?" Judge Andrews said he would try to give his "say" on that subject in his essay on the coming bee, that *ain't coming*. Convention adjourned till 2 p. m.

FIRST DAY—AFTERNOON SESSION.

An essay of B. F. Carroll, of Dresden, Navarro county, was read by the secretary.

[I will send it as soon as transcript is obtained.—Sec.]

Judge Andrews was asked if he could approve Mr. Carroll on the bee moth? To which he replied that he could not; that the so-called bee moth, more properly the *comb worm*, is not an enemy to the bee; that no colony of bees was ever destroyed by the bee-moth larvæ; they never infest combs used by the bees; that abandoned combs only became a prey to those worms. He was then asked why the books taught this fallacy? To which he replied that our books do not all teach it; that they had been read through the "glasses" of a barbarian tradition; he then opened Quinby's New Bee-Keeping, page 228, and read as follows: "Let it be distinctly understood by all beginners that the moth is not the cause of the decline of a once healthy stock. It simply takes advantage of the weakness induced by other causes."

Dr. Howard said that the so-called bee moth subsisted wholly upon the comb as constructed by the bees; that foundation made from pure wax was not attacked; that comb constructed upon it was infested only for the sake of the additional natural comb. He said that Judge Andrews called his attention to this a year ago, in a remark that the moth larvæ could not subsist upon pure beeswax.

M. H. Davis, of Grayson county, asked if these worms could subsist upon bee-bread?

Judge Andrews said he thought not, but could not speak from a satisfactory trial.

Dr. Howard said, that they could not; that they must have comb.

J. H. Manlove, of Fannin county, asked, "How long do fertile workers live?" Dr. Marshall said, that he thought they partook of the nature and longevity of the queen; that in their development they, perhaps, obtained a portion of royal jelly, the food intended for the queen larvæ, which caused a greater development of the reproduction organs. Judge Andrews thought that laying workers live just as long as other worker-bees.

Is there more than one fertile worker in a hive at one time, was asked?

Dr. Marshall said, that the number of eggs were not more than would be laid by one queen, but the manner in which they were deposited indicated the work of a plurality of fertile workers.

Judge Andrews said, that he had seen six workers laying eggs in one comb, at the same time.

Can we know when a hive is infested with fertile workers without opening it, was asked?

Dr. Howard said, that the appearance of dwarfed drones was evidence. Judge Andrews said, that unfertilized laying queens would produce dwarfed drones the same as fertile workers would.

It was asked, "Is there any difference in the appearance of the eggs of a fertile workers and those of fertile queens?"

Dr. Howard said, there was no difference, except that the workers deposited a multitude of eggs in one cell, and that often without changing her position; and again, they are attached carelessly along the cell-walls from extremity to base.

What is the best method to get rid of fertile workers, was asked by Judge Goodner?

Dr. Marshall said, give the colony a fertile queen. Judge Andrews approved the Doctor's plan, but preferred to give small quantities of young worker brood, at short intervals, and a young queen will soon succeed the worker pests.

Horace Welch, of Marion county, asked how long worker-bees live? Judge Andrews said they live 75 days in this latitude, the average life.

Will it pay to plant here, for honey, asked by Dr. Marshall? This was considered, by the convention, an important subject, and deserved our best attention; but as the secretary announced that an essay upon this subject was soon to be read, the matter was dropped.

Then came the question, by E. P. Massey, of Waco, will bees do as well in dense shade as they will where the sun reaches them most of the day?

Judge Andrews said, that the question embodied the extremes, that in the sun would be preferable in the early part of the season, and shade during July, August and September; that he preferred the sun to shine upon the hive till 9 o'clock a. m. and after 4 o'clock p. m.

What one fact, if generally known, would advance the cause of bee-culture more than any other, not now so known, was asked by Judge Andrews?

Dr. Howard said, that one of the greatest stumbling stones was the common idea that "bees work for nothing and board themselves."

Dr. Marshall thought that if the masses could be taught that honey is purely a wholesome and health-giving diet, while the fine, extravagantly high-priced syrups of to-day are a chemical compound, contaminated with glucose, which is daily undermining the health of the people; that the demand for pure honey would so exceed the supply, that many more persons capable of cultivating bees, would be induced to fall into our ranks.

Judge Andrews thought that the greatest drawback to the growth of this great source of wealth, health and pleasure, is the fear of the *sting*; that if the people could be taught that by the judicious use of the "smoker" the cause for this palsy horror can

be banished forever, that thousands of the brightest sons and daughters of Adam, that are now out in the cold world, would be brought happily into our fold.

Mr. W. T. Pryor, of Farmersville, wished to know the proper time to transfer bees from box hives. Mr. W. R. Graham, of Greenville, answered, "Whenever you find them in box hives."

Dr. Howard said, "Bro. Graham, you handle that subject most admirably."

Dr. Marshall said that during fruit-bloom was the time usually chosen, and he thought there were many good reasons for it.

The president appointed W. K. Marshall, G. R. Cooper and T. C. Goodner committee on resolutions, and W. R. Howard, H. Pearce and E. M. Wise committee on apiarian supplies and exhibits.

Adjourned till 9 o'clock, second day.

MORNING SESSION—SECOND DAY.

Dr. Marshall read an essay on "Extracted honey."

[Will send essay on when I get a transcript.—Sec.]

H. Welch asked, "When bees gather pollen are they likely gathering honey?"

Dr. Howard responded that many plants yield pollen when there is no honey to be gathered; not being secreted by the flowers, at such times the bees gather pollen alone.

H. Pearce asked, "Is a superabundance of pollen in a hive, in the spring, detrimental to bees?"

Judge Andrews replied, that there is no such thing as superabundance of pollen, in the South.

Judge Goodner asked, "Do any benefits accrue from natural swarming that cannot be secured by artificial swarming or dividing?"

Dr. Marshall said, that he had increased successfully by dividing, but that when the production of honey is the object, natural swarming is preferable; division is often attended with losses that ordinary foresight would not anticipate.

Judge Andrews said, that there were thrift and vigor attending natural swarming that could not be had in dividing; a new swarm does a land-office business; artificial swarms never get ready for our harvest, the horse-mint; they do not have just such a point in the North.

Mr. A. R. White, of Dallas county, inquired, "Can horsemint be cultivated here with profit?"

Dr. Howard said, that it could be cultivated with the greatest ease, but, thought it would hardly pay in this country to do more than scatter the seed on waste land.

W. R. Graham gave some interesting experiments in planting horsemint for honey.

Judge Goodner asked, whether settlement and cultivation of our prairies tend to decrease our honey resources?

The discussion here took a wide range with some difference of opinion, but the prevailing opinion was, that our volunteer resources are de-

new home, and so were not put to the test of cold weather. Their untimely failing must have been caused by something else than climatic influence. I have known queens bred in the North to do the same. On the other hand, I have had queens from Georgia which were unexceptionable in every respect.

The charge of inability to stand our severe winters, must apply with equal force to queens coming from Italy; while for other reasons I prefer home-bred queens, I believe that this complaint has never been made of imported ones.

If it is a fact that Southern-bred queens are inferior to those reared in the North, the result will be an injury to the business of Southern breeders, and a loss to Northern apiarists who wish to buy early queens.

I cannot speak of the BEE JOURNAL except in praise; the avidity with it seizes new subjects, and the ability with which it discussed them, makes it invaluable to those who would keep up with the times.

Detroit, Mich., May 21, 1883.

For the American Bee Journal.

Bee-Keeping in Canada.

JAMES SHANNON.

I have been interested in bee-culture for a number of years, but like many others, was content with the old box-hive and the old methods, and the result was a limited supply of honey for home consumption, and sometimes a little to spare. But about three years ago my attention was accidentally called to the scientific methods of bee-culture, and I at once became an enthusiast in the business, and went to work in good earnest to learn the principles of this pleasing occupation. While studying, I have been practicing, thus demonstrating the advantages or difficulties of different methods. After reading the standard works on bee-culture, I subscribed for the BEE JOURNAL, which has been a welcome visitor every week since.

I have wintered 7 colonies, 6 of which are in excellent condition, but one has dwindled badly. The weather here has been very cold and backward since the winter protection was removed. I think they should have remained in winter quarters until now. It seems to me that double-walled hives are almost a necessity to provide against this lingering cold in the spring, which so often prevails here; until this date, and even after, cold waves that greatly retard operations in the hive unless they have almost winter protection. I am experimenting in this matter. I have been greatly interested in the discussions about the coming bee. Surely, we should be as wise as the old patriarch who cared not whether his cattle were ring streaked, speckled or spotted; and, if we can bring out the good points by careful breeding, none need care about color or bands. I am trying to unite two valuable traits in my bees; one part are superior honey-

gatherers; the others, having a slight dash of Cyprian blood, have shown remarkable powers of building up. The only difficulty I have is the nearness of other bees.

I have sown 12 pounds of Bokhara clover, this spring, and intend trying other plants, believing pasturage to be a necessity. We have, however, good natural pasturage consisting of white clover, abundance of raspberries, and some basswood and golden-rod, and other plants upon which the bees work vigorously.

There is a growing interest in bee-culture here, and a good demand for colonies. I hope to report progress, from time to time, with the result of my experiments.

Wolverton, Ont., May 15, 1883.

For the American Bee Journal.

How I Get Bees into the Sections.

W. H. BALCH.

Years ago it used to be a hard job, sometimes, with some colonies of bees, even when all seemed propitious; while others, no stronger in numbers, were working with a will in sections, these would lay around for several days. Now, as soon as I get the hive filled with brood, I begin to open or ventilate the hives as fast as the bees will bear it and not chill the brood; I open the entrances a little each day, turn back the quilt, a little at a time, and soon. When the honey begins to come in, put on the sections, close all ventilation and the entrances as small as not to hinder them working. The hive is not cooled so much but that they have some bees to spare, and these will immediately go into the sections and begin work. Have one or more sections filled with natural comb, or foundation that was drawn out the previous year, and if you do not care for very much increase, watch the sections, and as soon as the first are filled, take them off and replace with empty ones; as the bees increase, give more ventilation. In this way I have prevented one-third of my bees, in a good honey season, from swarming; and many that did swarm, swarmed but once, and those that did not swarm, averaged a little over 300 pounds per colony, of honey in the comb.

Oran, N. Y., May 24, 1883.

For the American Bee Journal.

How to Make Out Reports.

W. H. STEWART.

There seems to be a general desire expressed by leading bee-keepers to collect and publish full and reliable statistics on bees and honey. Bee-keepers can never know their relative standing with other producing classes until they can obtain such statistics. To us it seems impossible to get a full and correct statement of our condition, products and prospects in any other way than to first get a full and correct report from each individual engaged in the business.

To do this, under the present condition of affairs, is no small matter. If each bee-keeper was taking a bee paper, and was able and ready to make out a full and correct report each year, then a committee could, by comparing those papers, approximate very nearly to the truth. But, unfortunately there are many bee-keepers who do not take a bee paper, or even take the trouble to borrow one to read; therefore, they cannot be expected to report; hence, it would have to be the business of some other person to pump a report from such men, and report for them.

It appears to be useless to depend upon assessors to gather these statistics, from the fact that in some States no account is taken of bees in the assessment. Again, if assessors and town boards should undertake to collect and report the full and correct condition of bee-culture in their respective towns, not one in one hundred of such officers know anything of bee-culture, and, consequently, could neither frame, ask or answer an important question on the subject.

There is yet another impediment in the way of getting even a correct report from those that do take and read bee literature. Many get a good crop of honey, and seem to be so overjoyed that they rush into print with the report, not stopping to ascertain at the year's end, whether or not bee-keeping has paid, all things considered. Others get discouraged when the year is, perhaps, half-passed, and report their discouragements, and then, may be, we hear no more from them. Others seem to be ambitious to excel in making outward show, and they double up as many bees as can be made to work together, and then take all their stores, and leave the bees to perish for the sake of reporting big yields from one colony, and, perhaps, a fair, aggregate report would show that the same man is losing money on his bees, all things considered. Others report good and honest as far as they go, but their reports not being full, are of but little value.

Allow me to give some examples of reports, and my reasons for thinking that such reports are in the end worthless. First, let me say that what I write on bee-culture, is only calculated for this northern latitude. Even in this region of long, cold winters, almost any one can manage bees safely and profitably through the summer seasons, but then comes the winters, during which the law of natural selection proves that the only road to successful bee-keeping is a well-arranged and closely-followed system deduced from reason, observation and experience.

To be useful, a report should embrace an experience for at least one whole year; not only so, but that year should begin and end at such dates, that we could learn from it what effect such and such management, through the spring, summer and fall had on the bees during the winter, and the manner they were wintered. I believe that all well-posted bee-keepers are agreed that if we begin in the spring with two colonies of bees

in equal condition, and from one take all the early honey, leaving only the late, unripe and inferior honey for winter stores, and give the other well-ripened and capped basswood or clover honey for winter food, the condition of the two colonies, in the spring, would be far different, whether outdoor or cellar wintering were tried.

But to the reports. In the BEE JOURNAL, page 59, Mr. H. Cripe reports as follows, under date Jan. 18, 1883: "Last spring I had 4 colonies of Italian bees (two strong and two very weak), they increased to 10 strong colonies, by natural swarming. The increase all came from 2 colonies, and I took 120 pounds of comb honey from them. I could have taken a quantity of extracted, but I had no extractor, so I thought I would keep it for spring feeding. After the honey season was over, I sold 2 colonies and bought 16 Italians and hybrids in Simplicity hives. * * * I packed 10 in sawdust and 6 in chaff; the other 8 I put in the cellar. They are all alive (Jan. 18), but I cannot tell how they will come out. * * * We have had a solid winter since Nov. 23."

Now, in giving the above report, we wish to cast no slur, or find any fault with Mr. C., but we want all to see how reports could be made of lasting good. He says on Jan. 18, "all are alive, but I do not know how they will come out." If this report had been held until next June, he could have told us how they came out; but as it is, we will not be likely to ever know how they came out, and even if he tells us next spring, then we must find this report and compare it with the spring report (which course is not as yet being pursued, that I know of); and even if we compare the two reports, this one, at least, does not tell whether the 2 Italian colonies that gave 6 swarms were the two that he sold, or whether they are packed in sawdust, or in chaff, or in the cellar, or whether the cellar is under his dwelling, where the light is often carried, or whether the cellar is made in a sand-bank expressly for bee-wintering, and how ventilated, what kind of hives the first 4 colonies were in, what kind of hives he put the 6 swarms in, and whether the 6 were out or indoors. Will Mr. C. please report in this month and finish out what he has begun in the above partial report.

In another report by Mr. D. H. Hopkins, the same page, gives us to understand about how he managed his bees last summer, and that on Jan. 9, they were all very quiet in the cellar, with no dead bees on the floor, but that there were more than a bushel of dead bees on the floor the year before at the same date.

Now, if Mr. H. had told us how he managed his bees through the summer of 1881, then we might, perhaps, figure out the reason why bees, in the same hives and same cellar (we infer that they were the same) should winter so differently in two different winters. The management through the summer, and mortality the following winter, should have been given in a report by itself; and in the spring

the summer management and wintering that followed should be given, then the two reports could be compared, and the results deduced therefrom.

In the report of the New Jersey and Eastern Convention, on page 10 of the BEE JOURNAL, it will be noticed by Mr. King's remarks, that it was the next thing to impossible to get any reliable statistics on bee culture. Again, on page 772 of the BEE JOURNAL for 1882, in the remarks by the editor of *Bee-Keepers' Magazine*, he says that no reliance whatever could be placed on certain statistics, that he had found emanating from the Department at Washington; and in his closing remarks, *urges* the necessity of some plan which shall give accurately the facts, and so enable beginners to enter on the business understandingly. I am of the opinion that it would be a good plan for our editors to furnish their patrons with printed blank reports about May 1, requesting the bee-keepers to fill out by answering the following questions, or a similar list of questions could be arranged by the editors counseling together:

1. How many colonies on May 1, 1883?
2. What strain of bees?
3. In what condition?
4. In what kind of hives?
5. What is your locality?
6. How did you manage them through the month of May?
7. How through June?
8. How through July?
9. How through August?
10. How through September?
11. How through October?
12. How did you prepare them for winter in November, and what kind of stores, and how much surplus through the season?
13. How did they appear to do through each winter months?
14. If in cellar or clamps, on what date did you set them on summer stands in the spring of 1884?
15. How did they do from the time set out until May 1, 1884?

It seems to us that a tolerable good and reliable system of management could be deduced from a few years' report as above, but that one-half or one-third of the reports made at random, will result in very little good.

Orion, Wis.

For the American Bee Journal.

Essentials of a Standard Frame.

J. W. PORTER,

Replying to Dr. E. B. Southwick's letter, on page 263, as an advocate of the Langstroth frame, I would state the reasons why very many have adopted it, above all other frames:

1. It affords a very much larger surface on top, than any deep frame. The largest surface for comb honey on top is the main point, for many of us have no success in side-storing. It favors the internal economy of the hive, inasmuch as bees can reach their stores sooner by climbing a less distance, in the many thousands of loads daily

carried in.

2. The same superiority is claimed for extracting from the second story, over deep frames.

3. It disturbs the bees far less, to draw up from a hive the frames filled with honey or brood, nine inches deep, than twelve inches deep.

4. If queen-cells are formed, they are less liable to accidents.

5. In case of a slight deviation from the perpendicular in setting the hive, there is less danger of the combs being fastened to the sides.

So much has the first points been esteemed, that many efforts have been made to carry it still further and make the frames less deep, but it appears that the standard Langstroth frame is a sort of happy-medium between the two extremes of shallow and deep frames.

That it sufficiently meets the requirements for concentrating the cluster in winter and spring is clear, judging by the great success of the army of bee-keepers who use it. It will be admitted by most of the apiarists, I doubt not, that the square frame, "American" or "Gallup," has advantages for winter-clustering, but we claim not enough to compensate for the reduced superficies on the top of the brood.

Where are the returns from such that can equal the reports we have from those using the Langstroth frame? Mr. Doolittle comes the nearest to it, but I forget the dimensions of his frame. But he has been greatly surpassed, as the records show. While it is my practice to confine frequently to eight Langstroth frames, for comb honey, I wish the space for ten frames above, and have it by inserting dummies below, on each side. Even then I have to tier up, in "the season," the honey racks. Having used both kinds, I have given such reasons as my own experience suggests.

Charlottesville, Va., May 24, 1883.

BOOK CLUBBING LIST.

We will supply the *American Bee Journal* one year, and any of the following Books, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage prepaid.

	Price of both. Club
The Weekly Bee Journal.....	\$2 00..
and Cook's Manual, 7th edition (in cloth).....	3 25..
Cook's Manual, (in paper covers).....	3 00..
Bees and Honey (T.G. Newman) (cloth).....	2 75..
Bees and Honey (paper covers).....	2 50..
Binder for Weekly Bee Journal.....	2 75..
Apiary Register for 100 colonies.....	3 50..

The *Monthly Bee Journal* and any of the above, \$1 less than the figures in the last column.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Letting Out Bees on Shares.

1. When bees are let out on shares, what are the conditions of the contract?
2. Who furnishes the new hives necessary for the increase?
3. Does the renter furnish all appliances for preparing the honey for market, or for only his share?
4. For what length of time are they generally let out for?

Mr. Heddon will confer a favor by answering the above through the "What and How" department of the BEE JOURNAL. As a rule, the bees wintered well in this county (Clinton).

HERBERT R. THOMAS.

Clarksville, O.

ANSWERS.—The "Bees on Shares" question, is one that I have studied considerably. In answering the above, I do so with a prejudice in favor of the laborer vs. the capitalist, a principle herein involved, though on ever so small a scale. Here are two facts:

1. Bees are to some considerable extent a risky property; their life and the amount of their stores being an unknown quantity. One should have a larger per cent. of income from such property, by three or four fold, than from a good, safe real estate mortgage.

2. On the other hand, the laborer should have an average income in advance of the "going wages." All this can be realized from the manipulation of bees, provided the bees are in proper hives, in a good location, and the work done by a faithful and learned man, and directed by experience and tact.

I will lay down the following terms as those which seem to me the nearest to being just, and the best adapted to both parties.

The one owning the bees shall furnish the place to establish the apiary. He shall furnish all the fixtures in ever respect. The laborer shall furnish himself nothing more.

The laziest tramp can turn and mend,
And be a man "for a' that."

The capitalist furnishes bees, apiary, tools, new hives for increase, comb foundation for surplus and brood departments, in full sheets; sections, shipping crates and everything, including his riper experience (which, it is supposable, he possesses). He shall have the diction of the general plan of management, while the rentor does all the work, and is dictator of

the detail manipulation. The division shall be as follows: Each party shall have one-half of the surplus honey, and when it is sold, each one shall pay one-half of the cost of sections, shipping crates and surplus comb foundation that is sold with that season's crop. The capitalist shall have diction over the whole crop, merely dividing the money for the same, unless the laborer give security for the payment of his half of the sections, foundation and crates, when the honey may be divided, and each sell his own as he chooses. The bees should be managed for securing the greatest amount of surplus possible, and discouraged from swarming, all that such management tends to do, but when they do swarm, they are to be hived and managed as are the old colonies. The increase belongs to the apiary, always; and any system that gives a share of the increase to the laborer, will defeat itself, and prove in the end damaging to both parties. The old system of half the honey and half the increase, and the lessee or laborer furnish everything, is illy adopted to modern apiculture, and would give the capitalist "the lion's share." Of course the surplus from the increase is divided equally, the same as that from the old colonies. All the reasons for settling on the above terms as the nearest just and best, all around, are too many for the room I wish to occupy now.

Foundation in Frames and Sections.

1. How full should frames and sections be filled with foundation?

2. Should the foundation in frames be fastened only at the top? I have been in the habit of fastening it in frames and sections only at the top, and leaving $\frac{3}{8}$ to $\frac{1}{2}$ inch space at the sides and bottom.

3. Would it do to fill the sections so full of foundation that bees could not pass through?

4. How soon, after the brood has been chilled, can it be detected by an amateur, and how?

5. In taking frames of brood from strong colonies to build up weak ones, should the adhering bees be shaken off, or could they be safely put in, bees and all, by smoking or confusing the weak colonies?

Bees in this vicinity are doing well. A neighbor has had one swarm come off already, and reports other colonies liable to cast swarms soon. Prospects are good for an abundant honey flow from white clover. J. M. BURTON.

Morrison, Ill., May 23, 1883.

ANSWERS.—1. In filling the brood frames I leave a space of $\frac{1}{8}$ to $\frac{1}{4}$ inch at the ends, and about $\frac{3}{8}$ at the bottom. In one-pound sections I leave

about $\frac{1}{8}$ at the sides, and $\frac{1}{4}$ to $\frac{3}{8}$ at the bottom.

2. I fasten my foundation to the top bar, and on to the wires woven vertically, eight in each Langstroth frame. I think you have had success with sections, but needed wires in the brood frames.

3. As far as the passage of the bees is concerned, I would not care for any run-way at the sides, only at the bottom, but I do not get as straight combs when the piece of foundation is fastened to the sides of the sections.

4. I have never had any chilled brood that I remember of. I think it will turn brownish a few hours after chilling.

5. I do not approve, as a general thing, of such exchanging at all; but where I do it, I shake off all the adhering bees and put in only brood about ready to emerge from the cells. Sometimes very young bees will kill a strange queen, and that, too, after much precaution.

SELECTIONS FROM OUR LETTER BOX

Bloom Promises Well and Fruit is Safe.

Here, in Belmont county, O., we have escaped the late terrible weather, with the exception of a few light frosts and 3 or 4 days of cool, cloudy, wet weather, which was pretty trying on the bees. The white clover and locust bloom promise well, and the fruit is still safe, as far as I have noticed.

R. M. DENHAM.

St. Clairsville, O., May 24, 1883.

Bee and Honey Show in Kentucky.

After a long silence as a correspondent to the BEE JOURNAL, I again pen a few lines. Our prospects for white clover honey was never better. Bees were storing honey and breeding comb up to May 19, when we had a big rain storm from the northwest, turning cold after the rain, with a severe blow for 48 hours. It was a cold blast, making us shiver with cold, and our bees could not get out, even for water. My apiary is in the best condition possible, and with one of Pelham's foundation machines, we are making beautiful foundation. We have the very finest of Italian bees, and the clover is very nice. Bees are beginning to build comb and store honey. Mr. Craycraft, of Salem, Ind., has my bees in charge, and we shall run them for both comb and extracted honey. Mr. Craycraft is well posted in scientific bee-culture, and is working my bees in a very satisfactory manner. Our State Society meets in Louisville next fall, and we want to make as fine a display of bees, honey and bee-fixtures as possible. We hope

honey producers and manufacturers of supplies (who will take an interest in the show) will write us what they desire to exhibit, so that we can secure space in the Industrial Exposition, which opens Aug. 1 and closes Nov. 1. As secretary of Kentucky State Bee-Keepers' Association, I will do all I can to make the exhibit a success. Every bee-keeper in Kentucky ought to have something on exhibition, and bee-keepers and manufacturers in other States are invited to help us. N. P. ALLEN.

Smith's Grove, Ky., May 23, 1883.

Cyprians, Motherwort, etc.

I have 53 colonies of bees; one being a Cyprian, which gives the most honey, and are as gentle as any other bee. I have not been stung by them yet, and I have had them nearly a year. A friend of mine says, "Give me Cyprians after this;" some say that Cyprians are hard to manage, but I cannot see it. Motherwort grows very easily. I have some of it, and will plant it all the time, as it blooms always; as fast as the old stock dies down, younger ones take its place, and I think it worth planting. It can be planted any place, or along the fences. G. E. SONNEMANN.

New Iberia, La., May 25, 1883.

Fruit Trees Blooming.

My bees have wintered very well. I only had 49 colonies in the fall, when put in the cellar; I lost two, by being queenless. We have had a cold spring, and I have had to feed some. Apple blossoms are just out; the first ones opened yesterday, and if it keeps warm, they will strengthen up pretty fast. D. S. MCCALLUM.

Big Creek, N. Y., May 26, 1883.

Bees in Fine Condition.

Our bees are in fine condition. The white clover is very thrifty, and with good weather will be apt to yield well. F. A. SNELL.

Milledgeville, Ill., May 27, 1883.

Prospects Favorable in California.

Our prospects are very favorable. We have fine late rains, and the bees are booming. R. STRATHEARN.

Scenega, Cal., May 20, 1883.

Gone to the South.

As frost, ice and cold winds had been the order of the day, up to May 15, I made up my mind to come South at once, and on the 17th inst., I chartered a car to Tullahoma, Tenn., and loaded on 67 colonies of my bees with household goods and started them South. On the 22d inst., with my family, I left Indiana; when we left, it was snowing and cold. We arrived here on the evening of the 23d, and found it pleasant and warm weather. My bees came through in splendid condition. I. R. GOOD.

Tullahoma, Tenn., May 26, 1883.

Prospects Flattering.

The bees are booming and prospects flattering. W. H. STOUT.

Pine Grove, Pa., May 28, 1883.

Destroying the Queen-Cells.

No doubt many have read in the books that when bees are making preparations to swarm, because of unfavorable weather or other causes, the cells will be at once destroyed. This has not always been the case with my bees. I found by experience, that sometimes (though not always) the young queens are allowed to hatch; and when such is the case, the first queen that emerges will destroy the remaining cells, and in a majority of cases, kill the old queen too. As this generally happens when our queens are needed the most, I think it is poor policy to let any capped cells remain in a colony when the conditions for swarming are not favorable. Although when the bees wish to supersede their queen, the young queen will seldom kill her mother; but in swarming, this is not the case; at least such has been my experience.

H. J. SCHROCK.

Goshen, Ind., May 29, 1883.

Correction.

In my letter on page 261, the printer, in mistaking the word *rather* in my manuscript for "either," and leaving out a word altogether in another sentence, spoils both. Allow me, therefore, to give the two sentences here as they were written in my manuscript, italicising the two words left out: "But it would be *rather* disingenuous to say that one colony of bees did all this, without giving any explanations. * * *

Now, please bear in mind, I do not wish to impeach the honesty or sincerity of a single correspondent."

ALLEN PRINGLE.

Selby, Ont., May 25, 1883.

Swarmed in a Hurry.

I wintered 20 colonies in Langstroth chaff hives. They wintered well, and came out very strong. Henry Alley recommends raising up the hives, a foot or more from the ground, so that they will not get snowed under. My experience is, that bees will do better if they are under a snow bank, then they would if they were elevated and exposed to the wind and cold. My bees were covered with snow, or nearly so, from the early part of the winter until early in March, then I shoveled out their entrances, and they had a splendid flight, and showed little signs of dysentery. I gave them a thorough examination about April 10, and found from 2 to 4 frames of honey that had not been touched in each hive (I gave them 7 Langstroth frames to start on). On the 26th of this month I lost a large swarm of bees, and as it was a little out of their common way of doing business, I will describe it. The queen was a hybrid, and very prolific. I had taken 4 frames of capped brood from it, to build up nuclei, but the hive was full of bees. I examined the hive the day before the swarm issued, and found several queen-cells started, 3 or 4 containing eggs, but no hatched eggs or larvae; so I felt sure the bees would not swarm in 7 or 8 days, so I left home at 8 a. m.; the swarm came out at

8:20; I returned at 9:15 a. m., and met the swarm a few rods from home, on their flight to the woods. There was no one to hive them, or I would not have lost them. I examined the hive, after they left, and found no eggs hatched yet, and I do not know how to account for their hurry. Can any reader of the BEE JOURNAL explain it? J. A. MURPHEY.

Sterling Station, N. Y., May 26, 1883.

Dysentery.

I have a colony of bees in my apiary that seem to me to suffer from dysentery, or rather from the fact of being unable to discharge their feces. The hive is surrounded daily, on the ground, with a quivering mass of animated bees, but unable to walk. In the morning they are all dead, and the process is repeated. Their bodies are distended and filled with a large amount of yellow matter. The colony is apparently in fair condition. What is the cause and the remedy? F. C. GASTINGER.

Ada, O., May 31, 1883.

[It is evidently a case of dysentery. It might have been caused by poor honey, or something of that nature. As the summer is now upon us, fine weather and new honey will remedy it all. If they are not gathering honey, give them some good white clover or basswood honey; or if you have none of that, some sugar syrup, made as indicated on page 283.—ED.]

Report for 3 Years.

I have kept bees for about 16 years; all of the time, except the last 3 years, being in Ontario. During all that time I never exceeded more than 25 colonies and 200 pounds of comb honey, once or twice, and thought myself lucky at that. I moved here (Michigan) in March, 1880, bringing with me 2 colonies with dollar queens. I moved them 28 miles from the railroad here on a lumber wagon; still they increased by natural swarming to 10 good colonies, and gave some surplus comb honey. I wintered them on the summer stands, and all came out strong in the spring of 1881; and during that summer they increased to 25, and produced 700 pounds of comb honey. Again they were wintered on the summer stands, with the loss of 2, which I think were queenless, which left me 23 in the spring of 1882. During that summer they increased to 63, besides 7 that left for the woods, and gave me 2,200 pounds of surplus comb honey. I again wintered them on the summer stands, and now May 22, they are reduced to 50 colonies; the past winter, and especially this spring, has been very hard on bees; several of my neighbors have lost heavily. I use the Fisher deep-framed hive, and fill the walls with sawdust. Bees do well here; there seems to be a constant flow of honey from early spring till frost. W. M. SHIER.

Marlette, Mich., May 22, 1883.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

 **Constitutions and By-Laws for local Associations** \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

 **The Central Kansas Bee-Keepers' Association** will meet at Manhattan, Kansas, on June 30, 1883.

THOS. BASSLER, Sec.

 On page 261, 33d line from top of first column, instead of "following," read "preceding seasons."

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages)..... \$1 00
" 100 colonies (220 pages)..... 1 50
" 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Special Notice.—We will, hereafter, supply the Weekly BEE JOURNAL for one year, and the seventh edition of Prof. Cook's Manual of the Apiary, bound in fine cloth, for \$2.75, or the Monthly Bee Journal, and the Manual in cloth for \$1.75. As this offer will soon be withdrawn, those who desire it should send for the book *at once*.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

Sample Copies of the AMERICAN BEE JOURNAL will be sent *free* to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL.
Monday, 10 a. m., June 4, 1882.

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—The nominal price of extracted is 7c. for dark and 9c. for light—here. The supply is abundant and sales are slow.

BEEWAX—None in the market.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The market for extracted honey is lively, and the demand exceeds the arrivals. Our stock is small and we are in danger of having sold out every day. We pay 7c. for good honey on arrival, the latter price for choice clover. There is a small demand for comb honey, and prices nominal.

BEEWAX—Arrivals of beeswax are plentiful. We pay 35c. for a good article on arrival.

CHAS. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—I sold, of the comb honey crop of 1882, up to the first of January, 1883, nearly 120,000 lbs; since January 1st to April 1st, sales have been slow, and yet 70,000 pounds have been disposed of.

There is, perhaps, a few tons of dark and buckwheat comb honey on this market that will not be consumed before the new crop comes into market. There has been 3 pounds of comb honey crop of 1882 offered in this market, to one of the crop of 1881.

Extracted honey has aggregated in sales 140,000 pounds. There is, perhaps, a good deal to carry over, yet on the market. Prices since the first of December, 1882, have gradually declined until the present date. At this late hour, holders are anxious to sell; hence prices vary very much.

BEEWAX—35c. 36c.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Stocks and the demand are both light. More or less difficult would be experienced in filling a large order for a straight lot.

White comb, 14@17c.; dark to 20@d, 11@13c.; extracted, choice to extra white, 8½@9½c.; dark and candied, 5@7½c.

BEEWAX—Wholesale, 27@28c.

STEAHNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Bull; light jobbing sales only. Comb at 10@14c.—Strained and extracted at 7@7½c.

BEEWAX—Sold lightly at 32@34c.

W. T. ANDERSON & Co., 117 N. Main Street.

CLEVELAND.

HONEY—Stocks of honey are running low with us. 1-lb. sections are all sold and there is a very light inquiry for such; would probably sell at 18@20c. 2-lb. sections are not in demand, and no sales to quote, asking 17@18c. Extracted no sale at 9@10c.

BEEWAX—Not offering.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—Our market is fairly active. We quote: ½ lb. sections at 30c.; 1 lb. sections, 22@25c.; 2 lb. sections, 20@22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.

BEEWAX—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatham Street.

 Do not send coins in a letter. It is dangerous and increases the postage unnecessarily. Always send postage stamps, for fractions of a dollar, and, if you can get them—*one-cent* stamps; if not, any denomination of postage stamps will do.

 Do not let your numbers of the BEE JOURNAL for 1882 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

Bingham Smoker Corner.

Large Smokers need wide shields. Bingham's have them, and springs that do not rust and break, and bellows that sparks and smoke do not enter. The Conqueror has all improvements made to date, and a 3x7 inch stove, and 5x7 inch bellows. Sent post-paid for \$1.75. Address,

BINGHAM & HETHERINGTON,
Abronja Mich.

All Excelling. — Messrs. Bingham & Hetherington, Dear Sirs:—I am now selling your Smokers almost exclusively. You are excelling yourselves in smokers all the time.

Respectfully, J. G. TAYLOR.
Anstin, Texas, May 10, 1883.

Cyprians Conquered.

All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am "boss." Bingham's "Conqueror Smoker" did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham.

G. M. DOOLITTLE.
Borodino, N. Y., Aug. 15, 1882.

During the following three months, Bingham Smokers will be sent post-paid, per mail, on receipt of the following prices:

The "Doctor" (wide shield)—3¼ in. fire tube, \$2.00
The Conqueror (wide shield)—3 in. fire tube, 1.75
Large (wide shield)—2¾ in. fire tube, 1.50
Extra (wide shield)—2 in. fire tube, 1.25
Plain (nar. shield)—2 in. fire tube, 1.00
Little Wonder (nar. shield)—1¾ in. fire tube, .65
Bingham & Hetherington Uncapping Knife.. 1.15

With thanks for letters of encouragement, and the absence of complaining ones, we tender to our thirty-five thousand patrons our best wishes.
Very Respectfully Yours,

BINGHAM & HETHERINGTON,
Abronja, Mich., June 1, 1883.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Friends, If you are in any way interested in BEES OR HONEY

We will with pleasure send you a sample copy of the *Monthly Cleaning and Bee Culture*, with a descriptive price-list of the latest improvements in Hives, Honey Extractors, Comb Foundation, Section Honey Boxes, all books and journals, and everything pertaining to Bee Culture. *Nothing Patented.* Simply send your address written plainly to,

A. L. ROOT, Medina, O.

PURE ITALIAN BEES AND QUEENS.

Tested and untested Queens, nuclei in Langstroth size frames, full colonies, queens by the half dozen, bees by the pound. Send for prices and particulars.

A. B. MILLER & SON,
Wakarusa, Elkhart Co., Ind.

QUEENS!

During June and July, I shall be prepared to furnish the **BEST OF QUEENS**, both tested and untested, from two different strains. 1. From my new strain, viz: a cross between the Brown, German, and dark leather-colored Italian. 2. Pure Italians reared from imported mothers. With my hives of all worker combs, using drone comb where I desire it only, isolated from other apiaries, I have the best of opportunities to control the mating of my Queens. I rear Queens under the swarming impulse only, and upon the true plan of getting the best and most vigorous stock. All orders filled in turn, and it is useless to hurry us.

PRICES:

Tested Queens (all selected) each,.....\$ 3.00
Untested before July 1, each,..... 1.50
Untested after July 1, each,..... 1.00

These are bottom prices in any quantity. Send for descriptive Catalogue to

JAMES HEDDON, Dowagiac, Mich.

I cannot supply any more **COMB FOUNDATION** during 1883; my stock is exhausted.

Muth's Honey Extractor,

Square Glass Honey Jars, Tin Buckets,
Langstroth Bee Hives, Honey Sections, etc.
Apply to **C. F. MUTH,**

876 and 978 Central Ave., CINCINNATI, O.

Send 10c. for Practical Hints to Bee-Keepers.

65 ENGRAVINGS.

THE HORSE,

BY B. J. KENDALL, M. D.

A **TREATISE** giving an index of diseases, and the symptoms; cause and treatment of each, a table giving all the principal drugs used for the horse, with the ordinary dose, effects and antidote when a poison; a table with an engraving of the horse's teeth at different ages, with rules for telling the age of the horse; a valuable collection of recipes, and much valuable information.

Price 25 cents.—Sent on receipt of price, by

THOMAS G. NEWMAN,

925 West Madison Street, CHICAGO, ILL.

\$72 A week made at home by the industrious. Best business now before the public. Capital not needed. We will start you. Men, women, boys and girls want everywhere to work for us. Now is the time. You can work in spare time, or give your whole time to the business. No other business will pay you nearly as well. No one can fail to make enormous pay, by engaging at once. Costly outfit and terms free. Money made fast, easily and honorably. Address **TRUE & Co.,** Augusta, Maine. 5A1y

FLAT-BOTTOM

COMB FOUNDATION,

high side-walls, 4 to 16 square feet to the pound. Circular and samples free.

J. VAN DEUSEN & SONS,
Sole Manufacturers,
Sprout Brook, Mont. Co., N. Y.

Given's Foundation Press.

PUBLIC SENTIMENT affirms that the **PRESS** is **SUPERIOR** for making Comb Foundation either in Wired Frames or for **SECTIONS**, and insures straight and perfect combs, when drawn out by the bees. Send for Circular and samples.

D. S. GIVEN & CO.,

1ABtf

HOOPESTON, ILL.

CHEAP! CHEAP!

LANGSTROTH HIVES!
SIMPLICITY HIVES!

All kinds of hives and surplus comb foundation, etc., etc. Having superior advantages for the manufacturing of hives and of procuring lumber low, I can furnish very low rates.

Send for descriptive circular.

European Honey & Wax Importation.

Some time ago we noticed an item in an English paper that, at a sale in Lisbon, Portugal, *sixty tons* of beeswax had been sold. This shows what an extensive sale and use it has in Europe.

The *Deutscher Bienenfreund* for May contains a table showing the amount of honey and beeswax received at Hamburg from foreign countries during 1881 and 1882. The amount of honey was as follows, from

	1881.	1882.
Havana.....lbs	550,000	525,000
Mexico....."	1,100,000	835,000
Chili and Peru....."	1,320,000	1,105,000
California....."	48,000	—
Domingo....."	450,000	270,000
Total.....	3,468,000	2,735,000

Of beeswax the amounts received were as follows, from

	1881.	1882.
Chili.....lbs	90,000	54,000
Venezuela....."	145,000	63,000
Angola....."	14,000	—
Madagascar....."	48,000	33,000
West Indies....."	38,500	12,000
Total.....	335,500	162,000

Honey is extensively used in Europe in the manufacture of honey wine, metheglin and cakes; for preserving fruit, and preparing medicine, as well as for table use, for which it is more generally used than in America.

One firm (Messrs. Field & Co.), in Paris, use ten tons of American beeswax per month in making candles for Catholic altars. The religious pageantry of Roman Catholic countries owe much of its splendor and influence to its altar-candles, each the tribute

of a thousand flowers, collected by millions of bees, leading the thoughts back, perchance, to the sweet and pure origin.

Its other uses are very numerous and important. The New York *Grocer* enumerates the following:

Its property of preserving tissues and preventing mold or mildew was well known to the ancients, who use serecloth for embalming, and wax for encaustic painting, as in the wall pictures of Pompeii, wax candles and tapers play an important part in the processions and ceremonies of the Roman Catholic church. Wax is used by manufacturers of glazed, ornamental wall papers, and on paper collars and cuffs for polishing the surfaces. It is used in varnishes and paints, and for the "stuffing" of wood which is to be polished, as pianos, coach work, fine furniture and parquette floors. Electrotypers and plasterers use wax in forming their molds. Wax is an important ingredient in preparations for covering surfaces of polished iron and steel to prevent rust. Combined with tallow, it forms the coating for canvass and cordage to prevent mildew, as in sails, awnings, etc. Artificial flowers consume much wax, and, despite the introduction of paraffine, ceresin and mineral wax, its use appears to be extending. One of the oldest of its applications is in the laundry, and in polishing wood-work.

Bees and Fruit.

A correspondent in the *Prairie Farmer* remarks as follows on this subject, giving the results of some experiments. "The much-discussed question whether bees injure fruit was attempted to be solved by a committee of the Warsaw Horticultural Society. The work was begun, but finally neglected and never finished. How much and what was shown is the purpose of this paper."

A committee of three was appointed in the summer of 1881, of which the writer was one—and on July 9th of that year, in conjunction with a noted bee expert, they began their experiments, with early peaches. Their first experiment was as follows: They took three peaches of equal ripeness—two of them with the skin

slightly punctured, by insect or bird, and one which the skin entirely sound and unbroken. The punctures in the skin of the two were small, say about the size of a pin-head. These three peaches were carefully handled, and were taken and placed in a hive with a strong swarm of bees.

Result.—The next day, which was Saturday, and just 24 hours afterwards, the hive was opened and the peaches examined. The two punctured ones were found to be partly eaten by the bees, while the one with unbroken skin remained whole as at first. They were all replaced again in the hive. On Monday, at the same hour—which was 48 hours from the last examination, and 72 hours since the peaches had been taken from the tree—they were again examined. This time the two were nearly consumed, and the one was considerably eaten.

The query here presented itself to the committee: Did the bees begin on the third peach while its skin was yet intact, or did they wait till it, by its decay, became broken? That single experiment could not decide that important point. At the period of the first examination, that peach was still whole and seemingly sound, but as two more days intervened before it was examined the second time, it is quite possible that it may have decayed so far as to open the skin before the bees began their work on it. It is affirmed by bee physiologists that the bees have no teeth or other instrument by which they could perforate the skin of a sound ripe peach. And they stoutly maintain that bees do not originate the trouble, but only follow after some other depredator. This single experiment of the Warsaw committee, though not conclusive, goes far to prove that this theory of the bee men is the correct one.

Numerous other experiments and examinations were made subsequently by individual members of the committee, in regard to peaches; but none worth reporting in reference to other fruits.

In one case, five peaches were designated as they hung on the tree. One of them was nearly eaten up by the bees, one about half eaten, two others less so, and with no sign of decay about any of them. The fifth was entirely whole, with the exception of one little round puncture the size of a pin's head; and another the size of a grain of rye. These were both located at the ripest and softest side of the

fruit. No evidence of rot was visible. The origin of those punctures was unknown, but as at the time of the selection the bees were busy on the whole five, it was only a question of time—an hour or two—till they would all be consumed.

It may be mentioned, that in these experiments the big black ants were generally observed on the trees; and it has been suggested that they may be the depredators which make the original punctures, and open the way for the bees.

These experiments, however imperfect and unsatisfactory they may be regarded, taken in connection with other known facts, have convinced the writer thus far in the matter of the main question: That bees do not eat ripe peaches that are, if not to say absolutely sound, at least marketable.

Future experiments, it is hoped, will be made by that committee, as well as others, as to their depredations on other fruits.

What the Weather Will Be.

Prof. Berner, of Vevay, Ind., translates for the *Indiana Farmer* the following from the Latin, showing observations gathered from the most reliable sources in England, embracing years from 1677 to 1799, being 122, as follows:

1. When the vernal equinox is not preceded or followed by the usual equinoctial storms, the succeeding summer will be dry at least five times in six.

2. If easterly storms occur on the 19th, 20th or 21st of May, the ensuing summer will likewise be dry; the same characteristic applies to storms, from whatever direction, on the 25th, 26th or 27th of March, viz., a dry summer will follow.

3. When storms happen from or between the 17th and 23d of March, having directions from the west southwest, the succeeding summer will be wet five times out of six. In England, when both winter and spring are dry, they are always cold, but when these two seasons are wet, they are usually warm: on the contrary, dry summers and autumns are most always hot, and wet summers cold; hence, if the humidity of any special season be determined, an approximately correct idea may be formed what the prevailing temperature will be.

4. A wet autumn, succeeded by a mild winter, is generally followed by a dry and cold spring, which will be unfavorable to the growth of vegetation.

5. A wet summer is almost always succeeded by a severe cold winter, because the terrestrial heat has been carried off by evaporation: it has also been observed that wet summers promote great proficiency on the white thorn, so that an unusual fruitfulness of the shrubs is considered a presage of an intensely cold winter.

6. A severely cold winter is also indicated by the early departure in the autumn of cranes and other migratory

birds, because these birds never leave for a southern climate until the cold has commenced in the higher northern regions.

7. When the month of September is showery, it seldom rains during the coming month of May, and, the contrary, should September pass without showers, the following May will be rainy and wet.

8. When, in summer and autumn, the preponderating wind is from the southwest, or when the temperature is unusually low, profuse rain may certainly be expected at the end of the season.

9. Tempestuous storms and other violent commotions of the clouds, produce a crisis in the atmosphere, which is followed by a succession of several months of fine or boisterous weather, of whatever the incoming change may be.

10. A mild and rainy winter is always followed by a profitless summer.

11. When rainy weather prevails during a moon, the change succeeding will be fair weather for several days, after which rain will again set in; but when fair weather prevails during the moon, and the succeeding change be rain, fair weather will again return after the fourth or fifth day of the moon, and continue as before.

12. The most decided indication for fair weather, is the apparently great elevation of the celestial concave, and an evident disposition of the clouds to dissolve and vanish away.

Keystone Convention.

The "Seed Time and Harvest" gives the following report of the above named Convention:

We had the pleasure of attending a meeting of the Keystone Bee-Keepers' Association at Scranton, a few days ago. This is the only society of the kind in Northeastern Pennsylvania, and much interest was manifested by those present. The society numbers some fifty members, owning from six to two hundred colonies of bees. The questions discussed were: The Production of Surplus Honey, Wintering Bees, and Rearing Queens. Mr. J. Vandervort, of Laceyville, Pa., the inventor of the Vandervort Foundation Machine, was present, and exhibited some of the finest sheets of foundation we ever saw. All present agreed that a much larger yield of surplus honey could be secured by the use of foundation, than without it. It was generally agreed by those who had tried it, that the foundation for the lower frames or brood chamber, should be secured by fastening with fine wire drawn through the frames several times from top to bottom. These wires stiffened the frames and kept them from sagging, a fault which is quite common in unwired frames, and results in the breaking down of combs in hot weather. For the section boxes, small triangular pieces of thin foundation were recommended.

Different methods of wintering were described by the members present, and, as most of them had lost more or

less bees, it was agreed that no perfect method had been discovered yet. Mr. George C. Green, of Factoryville, who had lost a very small percentage for the past four years, advocated the use of the chaff hive, as also did several others. There appeared to be no professional queen breeders present, but a few chapters from Mr. Alley's new book on Queen Rearing were read, and proved to be very instructive.

It was decided to make a Society Exhibit at the next Lackawanna County Fair, and we presume that some fine specimens of the work of the industrious little insects, will be exhibited.

Prizes for Honey.

Messrs. H. K. & F. B. Thurber & Co., have issued the following Circular to bee-keepers:

First-class, uniform, well-packed honey, always sells quicker and for more money than honey of irregular grades, and it is, therefore, important for both dealers and producers to have honey marketed in the most desirable form. To interest producers, and induce them to attain this result, we have decided to offer the following prizes:

For One-Pound Sections.—For the best average crop of white honey, put up in one-pound sections, one first prize, consisting of a set of Appleton's Encyclopedia, 17 volumes; value, \$85.00. For the second best, one second prize, consisting of a complete set of Chambers' Encyclopedia, 10 volumes; value, \$30.00.

For Two-Pound Sections.—For the best average crop of white honey, put up in two-pound sections, one first prize, consisting of a set of Appleton's Encyclopedia. For the second best, one second prize, consisting of a complete set of Chambers' Encyclopedia.

The requirement will be a uniform grade of white honey, well fitted around sides of sections, neatly capped over, glass thoroughly glued to sections, and packed in clean, smooth, neat crates, as well as sections.

Where parties do not send us their crop, judgment will be rendered from a sample of five (5) crates, accompanied by an affidavit of the producers that it represents the fair average of his crop, and for these we will pay the New York market price for this grade of honey. The judges are to be the editor of the *New York Bee and Poultry Magazine*, the secretary of the Northeastern Bee-Keepers' Association, Mr. P. H. Elwood, of Starkville, N. Y., Mr. C. G. Dickinson, of South Oxford, N. Y., Mr. W. L. Tennant, of Scholharie, N. Y., and Mr. McCaul, who has charge of our honey department. This competition is to be open to any bee-keeper in the United States or Canada, and is to take place October 18, 19, and 20, 1883.

The Central Kansas Bee-Keepers' Association will meet at Manhattan, Kansas, on June 30, 1883.

THOS. BASSLER, Sec.

A Well "Timed" Mark of Respect.

Mr. C. N. Abbott, who nine years ago started the *British Bee Journal*, was, in January, succeeded by the Rev. Herbert R. Peel, as previously stated in this paper. It is with pleasure that we record the fact that the bee-keepers of Great Britain have presented him with a substantial "souvenir," showing that they are not unmindful of his labors in behalf of progressive and scientific apiculture. The *British Bee Journal* informs us that "the testimonial took the form of a handsome black marble dining room clock, designed after the style of the temple at the foot of the Acropolis at Athens, with bronze bas-relief figures representing priests sacrificing to Minerva. Affixed to it was an inscription-plate stating that the clock had been presented to Mr. Abbott from a few well wishers and friends, as a token of their appreciation of the services rendered to bee-keeping by his establishment and editorship, for upwards of nine years, of the *British Bee Journal*. Also a framed illuminated Address on vellum, with the names of the subscribers to the fund arranged in alphabetical order."

The Rev. Herbert R. Peel, his successor, in the editorial chair, made the presentation with the following remarks:

"He had been informed that this clock was called the 'Acropolis' clock, and the Acropolis was not very far distant from Mount Hymettus. Milton is his 'Paradise Regained' says:

"There flowery hill Hymettus, with the sound
Of bees' industrious hummur oft invites
To studious musing."

And he had been led to some misgivings in connection with the classic temple just referred to. Eighteen centuries ago there stood under the shadow of the Acropolis, a man striving to convert a city to the Christian faith. This man had to contest against a great mass of ignorance and superstition; and it had struck him that Mr. Abbott stood out, to some extent, as a similar example of a man working hard and single-handed to enlighten the ignorant and combat superstition. Their zealous friend had undertaken to teach the whole British nation on the subject of bee-keeping when he started the *Journal*. At the commencement of this task he was alone, as St. Paul had been. He had a number of difficulties to contend against, mostly those of apathy and want of sympathy. Even after 6,000 copies of the *Journal* had been sown broadcast over the length and breadth of England, and 5,000 circulars distributed, only 200 subscribers came forward to assist. This result was

quite enough to make any one despair. However, Mr. Abbott did not yield to the adverse wave, but fought on unflinchingly, and, after a considerable time, had the satisfaction of seeing his endeavors rewarded by the formation of the British Bee-Keepers' Association, and the establishment of metropolitan shows, which have been held, with one exception (in 1877), in London annually, for several years past."

"Mr. Abbott said that he felt somewhat embarrassed by the exceedingly kind and flattering remarks of Mr. Peel. All that gentleman had said of his early experience in regard to the cause they all felt so much interested in, came back on his mind with double force. There were difficulties, but having put his hand to the work, he determined to overcome them, feeling sure that in a good cause, with truth for his guide and honesty for his intention, he was sure of at length winning the support of the better class of bee-keepers in the country."

"In selecting a clock for him, they could not have chosen anything more suitable for a presentation. He looked upon a clock as he looked upon an honest man, because if it be a good clock, it always shows a face that one is pleased to look on, that is, a face that always tells the truth. This beautiful time piece would be his future companion, and whenever he looked on it, his memory would recall the excellent friends that he had made by a consistent course of conduct which he had always maintained in the *British Bee Journal*."

"There was not a single motion in the clock, but what was measured, from the second to the minute, from the minute to the hour, and from the hour to the day; and there was not in the *British Bee Journal* a single mark that flowed from his fingers, from the letter to the word, and the word to the sentence, but what was also measured, and measured by himself in the hope that it would be understood and appreciated as being strictly true, and written for the honest purpose of benefitting his fellow creatures."

"A clock, however, sometimes gets wrong, owing to its machinery being out of joint; so also he feared there must have occasionally been some little things out of joint in his conduct of the *British Bee Journal*, of which no one could be more sorry than himself. He was proud to see so many friends around, to welcome him on the present occasion, because he felt assured of their sympathy and acquiescence in the honor which had been done him that day. He could but express his heartfelt gratitude for their extreme kindness, which would always live in his memory."

In commenting on this, the *Bee and Poultry Magazine*, of New York, says that it "shows American bee-keepers how greatly the Europeans excel us in their courtesy and kindly wishes to those in the same profession. We hope the day is not far distant when American bee-keepers may feel to-

ward each other the same generous, hearty good will." These are our sentiments exactly. Nothing is so disagreeable and disheartening, as the jealousy and strife persistently indulged in by a few bee-keepers and conventions in this country, trying to antagonistically array the East and the West. Such should learn a lesson from the above, and hereafter strive only for harmony, unity and fraternity.

Southern Exposition at Louisville.

This Exposition, which commences Aug. 1, promises to be of the greatest importance to the South. Bee-keepers should avail themselves of the opportunity to have a grand Bee and Honey Show there. Mr. Elias Thomasson, who lives at 1015 H Avenue, Louisville, Ky., writes us as follows, on the subject:

Louisville is a city of 150,000 inhabitants, but it has no depot for bee-keepers' supplies. We would welcome a good man here, to meet the wants of Kentucky and the whole South, to supply everything needed for the trade. He will meet a hearty welcome.

Doubtless you have learned, by the newspapers, of our proposed Exposition to commence the 1st of August next, to last 100 days. The building, covering 13 acres, is already far advanced, and will be ready to receive goods, the 15th of July next, for exhibition. Two New York City bands get \$35,000 for their services, and also a \$10,000 organ has been bought for the occasion.

No man has made application for an exhibit of apian supplies. Who will come? Send to me and I will forward the blanks necessary to make application, by return mail. There is no charge for exhibiting honey; any quantity of it; but I think \$25 will be charged if manufactured articles are offered for sale, but that is not yet positive, as the superintendent could not give me an answer on his own responsibility.

Our people are expecting 1,000,000 of strangers to visit the Exposition, and, I will add, 1,000 men, who keep bees, in some sort of hives, will be here. What a chance! Who will take it? I am on crutches, but my heart is very full.

The Bee-Keepers' *Exchange* has again changed hands. Messrs. Colgrove & Ullery are now the publishers.

And a change has been made in the proprietorship of the *Magazine*. It is now published by King & Aspinwall.

The AMERICAN BEE JOURNAL gives friendly greetings to the new publishers all around.

CORRESPONDENCE

For the American Bee Journal.

Ventilation of Bee Cellars.

S. CORNELL.

Mr. Allen Pringle's article, on page 167 of the BEE JOURNAL, pretty fully meets the requirements of "a rousing article on how to ventilate a damp cellar." He says it is scarcely practicable to put in a sub-earth pipe after the cellar is built, but I found no difficulty whatever. We just carried the excavation up to the cellar wall, and then broke a hole through for the pipe. After the stones were again built in, and the earth replaced, all was close. If possible, sub-earth pipes should be laid as much as 5 feet below the surface, because it is said that at that depth the thermometer ceases to show the daily fluctuations of temperature. The temperature is probably nearly 50°, which is said to be the uniform temperature of springs of water after running for some distance under ground. It will be readily seen how much easier a uniform temperature can be maintained in a cellar, the walls of which are surrounded by soil, a little below 50°, than in a room above ground, whose walls are exposed to strong winds and the temperature constantly varying.

Mr. L. C. Root, who winters from 100 to 200 colonies with uniform success, takes the supply of fresh air from a warm room above. To do this successfully there should be a strong exhaust current from the cellar to the stove pipes or chimnies above, and the only opening for the ingress of air should be through the floor, as far as possible from the point of egress.

The ventilation of repositories not connected with artificial heat is often very faulty. Air has weight, and it requires force to lift or move it out of an apartment in order that pure air may take its place. Perfect ventilation is never automatic. I think if the particulars regarding Mr. Doolittle's new wintering cellar, for instance (see page 741 BEE JOURNAL for 1882), were submitted to a competent engineer for an opinion, he would be likely to say that under some circumstances the current would move in the desired direction, under other circumstances there would be no current at all, and again, that the current might flow in the opposite direction from that desired. I have long held the opinion that Mr. Doolittle's bees were either killed or half poisoned by their own breath, in his old "mud hut." The idea has been recently thrown out that while bees are in their semi-torpid state, it is better that the surrounding air should be foul, because they will not live so fast, and will come out younger in the spring. I think this position is untenable. It is true the respiration is lower while they are apparently dormant, but if supplied with pure air,

they will make the fewer respirations per minute. They, at all times, consume some food, and for the purpose of combustion some oxygen is required. If the air only contains a reduced proportion of this, they will be obliged to breathe faster to get the necessary quantity, like the traveler who said he had to drink a great deal of water in order to get a little tea, only in the case of the bees, the extra quantity of foul air re-breathed is positively injurious. In regard to supplying bees with pure air, it is like what the squaw said about the whisky on being remonstrated with for having taken a little too much. Her reply was that a little too much is just enough. So with the bees, we need not be afraid to give them, if possible, a little too much pure air. The want of an exhaust current in such cellars as Mr. Doolittle's, may be very simply remedied by placing a large lamp in the pipe leading to the outer air. Some of the best engineers recommend using lamps or gas jets, as a makeshift, to ventilate small apartments, and I see by the report of the Board of Health for Ontario, that such an arrangement is used successfully for ventilating a part of the General Hospital at Toronto. Those who may desire to get all the details will find them in Gouge on Ventilation, published by D. Van Nostrand, N. Y.

My observations on the condition of the air in my cellar during the past winter, have led me to the conclusion that if we are to have the dampness as well as the temperature under our control, the sub-earth pipe must be of a material which is impervious to moisture. The pipe bringing air into my cellar is of pine plank, having a cross section of 36 square inches, and running 140 feet through a wet soil. I found that the air, as it entered the cellar, was excessively moist when it should have been comparatively dry, on account of the increase of temperature as it passed through the pipe. The relative humidity was generally from 90 to 95°, but sometimes the air was completely saturated as it entered the cellar. For instance, on the 8th of March, when the air outside was 2 above zero, the air entered the cellar at 36°, and was fully saturated with vapor. Now, air at 2° is capable of containing nearly six-tenths of a grain of vapor per cubic foot when saturated, but the air outside was not saturated, and consequently contained less than that quantity. Saturated air at 36° contains about 2½ grains of vapor per cubic foot. Therefore, in passing through 140 feet of wooden pipe, the air must have acquired at least 2 grains of vapor per cubic foot. Again, on the 8th of April, the air outside was warmer than that in the cellar, but the nights were still cold. In the evening, as the temperature was falling, I watched till the thermometer outside and in the mouth of the pipe in the cellar, showed exactly the same temperature, 42°. The relative humidity should also have been the same, but there was a difference of 23°, the relative humidity outside being 67°, and that of the air as it entered the cellar 90°.

My conclusion is that for sub-earth ventilation, we require vitrified sewer pipe securely cemented at the joints. In this way only can we have dampness under control and exclude foul gasses. It is possible that with such a pipe the air might be found to be too dry. The exact degree of humidity at which bees can be kept in a cellar for six months in the best health has, I believe, yet to be determined, but until we have more information on the point, I think it will be safest to aim at about the average relative humidity of summer; in Ontario this is 74° of moisture out of a possible 100°.

Your readers may desire to know how my bees wintered in such a moist atmosphere. I am pleased to be able to report that they did pretty well. On the 3d of November last, I put in 65 colonies, and on the 16th of April, I carried out 64 alive. One had starved, three were weak, and another has since been found to be queenless. There was not a square foot of moldy comb in the whole lot. There was a little spotting in some of the hives, but so little that it need not be taken into account. When they were set out, the discharges were not copious, nor yellow and watery, but small and dark colored. I had no swarming-out or other troubles, although they were set out promiscuously between seven and nine o'clock in the morning.

Possibly some one will say that this experience is rather against the theory I have been advocating, that a damp atmosphere is one of the main causes of dysentery, but wait a little; the above is only a partial statement of the facts. Evaporation will take place in an atmosphere having a relative humidity of 90° or 95°, provided the air in contact with the evaporating surface is constantly changed. The wash will dry in such an atmosphere if there is a wind. My bees were in very moist air, but they had very good ventilation, and had the means of keeping as warm as they required to be. My cellar is small, the cubical contents being only 660 feet, or when the hives are in, say 500 cubic feet of air. There are two exhaust pipes connected with stove pipes above, changing the air very frequently. Two colonies of bees in closed-end Quinby frames were placed side by side separated by a thin veneer of wood, and these were tiered up three in height. The frames were raised 2 inches above the bottom boards, and one side of this space was left open. The hives were covered with thick quilts of sheep's wool over a "Hill's device." A peep under these quilts at any time would find the bees quiet, dry, snug and cosy. On account of the heat being so well confined by the quilts and of the heat from the adjoining cluster, many of the colonies clustered out in the open space between the bottom board and the frames, the greater part of the winter; some of them for 120 days. Some bee-keepers would probably call this "high pressure" as to the temperature of the air in the cellar, but it was not, for a thermometer placed midway between the floor and ceiling, averaged about 40°. Early in the

winter, in a few hives, the dead bees began to drop from between the combs to such an extent that soon the heaps reached to the frames, and these heaps of dead bees were removed two or three times. If the frames had not been raised, the ventilation of the hives would have been effectually stopped. The bees dying thus were not distended, and showed no signs of dysentery. I increased from 39 to 65 after the 1st of August, last season. Possibly some of my bees were prematurely old. I fed 1,025 pounds of loaf sugar last fall, and did not discriminate against combs containing pollen. I think my past winter's experience shows that bees may, with very good ventilation, be wintered in a very moist atmosphere, and that they may be so "clothed" as to cluster out in an atmosphere at 40°. I attribute my success to extremely good ventilation. I lost extensively in the same cellar during a previous winter through want of ventilation. I may give the particulars at a future time.

Lindsay, Ont., May 12, 1883.

ERRATA.—In the 12th line from the top of the second column, page 281, there should be a minus sign before 82. The want of it makes an error of 16%. Then the figures 545 and 2126, a little further on, are made a thousand times too great by the omission of a decimal point before the first 5, in the first case, and the substitution of a comma for a decimal point, between the first 2 and the 1, in the second case. There are other typographical errors of minor importance. S. C.

Bee Pasturage in Maine.

DR. J. A. MORTON.

I do not know much of this shrub which is referred to by Mr. Alley in his lately published "Bee-Keepers' Handy Book," unless it is our common white alder, found growing wild so plentifully on low lands. If it is, you are all familiar with it. It is a clean little tree, bearing an abundance of bright red berries, of a sweetish, bitter taste. I do not know about its flower, but think you had better take observation of it this season, and govern yourself in regard to it, as it proves itself pleasant to the bees. It would make a good hedge row.

The basswood, or American linden, is the most important honey-yielding tree in the whole State. It is well known to all bee men, and I only call attention to it, for the purpose of urging you to stop cutting it for timber at any price. Let something else take its place in the lumber yard, and keep it growing for the bees; also propagate it by setting out trees in low places, and along the numerous little streams in pastures, and along streets and roadsides and by fences, and even in woods where the growth is scattering, or the ground is cumbered by dwarfed spruces or other evergreens. Where nothing but trees can grow there set the basswood. The locust mingled with it or in close

proximity, on woody pastures, on the more barren ridges and sandy knolls, will grow quite fast, and soon bear flowers and become valuable for timber.

In the last part of the honey season the wild bloom is quite plenty and

useful. Fireweed on the meadows and river banks; and goldenrod on the dry, worn out sandy plains, in fields and pastures where nothing else will grow, are quite good honey plants and help out the bees nicely—still I am not very partial to them, for no stock eats them, and they are only useful for their honey, and the syrup from granulated sugar is as good if not better for wintering, but in this matter let every man suit himself. The wild aster and frostweed are the last honey plants of the year, if we accept sweet clover and motherwort, which last from the first flowering till the severest frosts kill them down. Motherwort, catnip and some few others are good weeds to sow in waste places not fit for other flowers, but they should be sown in considerable quantities to be of any benefit. A little patch of these plants are an injury because the bees are quite fond of them, and are diverted from a larger extent of other flowers not so pleasant to them but yielding much more honey, and more profitable to the bee master.

To those different trees, shrubs and plants, you can add such as you find by experience good for the purposes intended. Buckwheat is a good grain for feeding, and generally pays for cultivation in its yield, but is quite uncertain for honey. To some it will be profitable to raise, to others it may not. Try it, if you like.

I wish now, having mentioned in detail the leading honey plants of our State, to give a rational, easy and economical method of renovating any of these exhausted and worn out lands to which I have called attention, which will enhance their value year by year, and at the same time give you a fair percentage on the investment by an immediate return in the increased production of honey. If you are the fortunate or unfortunate, just as you may please to think it, owner of such property, not worth the trouble of repairing the fences every spring, for what it will produce through the summer, and, perhaps, turned out to common, go and "survey the landscape o'er" and decide that you will do something for the cause of agriculture and apiculture, for they go hand in hand in this enterprise.

If you have several pastures take the one nearest to the bees, first. If quite small, and you can possibly do so, exclude all stock from it for a year at least. If it is large and you cannot lose the use of the whole of it for the season, partition off a part of it by fencing in more or less, but as much as you can; and by using the loose rocks for this purpose, you gain two points, you have a substantial fence and get rid of the rocks. It pays to snug up rocks in pastures as well as in fields. Should there not be rocks which can be easily handled in sufficient quantities to complete this fence, finish it with the scattering spruces, firs, and other stunted evergreens within the enclosed part, which are only a damage, as they only poison the land for grass. Stumps and logs can be used for this purpose also.

Now go over it and cut every stunted evergreen from them—for nothing will grow under the shadow of such trees—dig up root and branch, running junipers, sweet ferns, hard hacks, brakes and all; removing stumps if convenient, and either pile up in small heaps to burn; or what is better, leave them to decay on the ground, for a cord of rich rubbish left to rot, fertilizes ten times as much as its ashes after being burned. Should there be scattering red or rock maples, elms, willows or other trees producing nectar bearing flowers, especially basswood or locusts, by all means let them stand, and if they are not in sufficient quantity, draw on the woods or other sources for enough to fill the complement. Or, if the soil is suitable, and sheep are to occupy the land, it would be a more excellent plan to set native grown apple trees of the hardy winter varieties, and in a few years, by a little extra pains, you will have a nice young orchard. None of these trees need be set in a regular line or order, but single or in clumps in very rocky spots or places where the grass will not grow or is inaccessible to the stock. Of course, before setting these trees the land must be plowed, if it can be done even poorly, and smoothed off, with some dressing, the more the better, such as stable manure or muck, or ashes, or even plaster will help it some, but be as generous as you can, and you will never regret it.

Having got the land all ready for the seed, be liberal with that also, for you can well afford it, and, if you wish to make the bees happy, sow from 5 to 10 pounds of sweet clover to the acre, or its equivalent of White Dutch or Alsike. I should prefer to have them sown separately, but you may like to mix them—do as you please about this. To these clovers you may add the seeds of good pasture grasses, if you wish to favor the stock which is to occupy the pasture, rather than the bees; but remember one thing, herds grass is not good for this purpose, the cattle soon kill it out.

Now, perhaps, some will say it is too late to do all this when there is scarcely time to get in the regular crops. That is all true; but try to get in an acre or two of sweet clover, or White Dutch, or Alsike, and make the bees happy, and you can leave the balance of the pasture to work on by odd jobs through the whole season, and, by fall, you will be all ready to sow the seed, or at least by early spring. But in that case the cattle must be kept out next year instead of this. All I have said of the small pastures will apply equally to the large, whether mostly clear of woods or partly in forest growth; but let the forest be divided off from the cleared portion as much as it can be, for woods are not good pastures, excepting basswood for bees, the grasses and tender plants will not grow there, particularly is this true of evergreen woods. All worn-out pastures, old orchards and mowing fields, may be treated in the manner above indicated with variations to suit each particular case, only be free with the manure

cut, and do not draw on the bank till one or two years' interest has accrued, and do not let the cattle in during spring and fall. Perhaps some may wish to try buckwheat in order to get immediate returns for their outlay, and because they can sow it later in the season than clover. There is no objection to this, if they plow it under after the bees have worked it, or let lay on the ground and decay. But the latter plan is liable to the danger of the ripened grain re-seeding the ground and coming up next year and choking the clover out. This will not pay. If turned under, the ground must be smoothed off and well seeded with the clover, and will need a little fine dressing, ashes, plaster or phosphate as a starter.

But some will say: "This is altogether too expensive; no man can afford to go over his pastures in this way; it would cost a fortune." I think no man can afford to let his pastures go on as they have for the last 50 or 100 years. As the man said in the storm at sea, "something has got to be done." One great disadvantage of the present condition of pastures is this: There is no fence between forests and cleared land, or what is usually denominated cleared land, and the stock drop most of their manure in these woods or along the little streams in out of the way places, and it is lost for fertilizing purposes. If these fences were put up, they would be kept in the best grazing, and leave the dressing where it would do the most good. The growing forest would not be fed down, and the smoother places would be enriched, and, perhaps, by a little attention in keeping down shrubs and weeds, the forage would be sweet and tender.

But there is a cheaper method, though it is not so thorough, and I doubt whether it would be much cheaper in the end. That is, to go over the pasture by odd jobs, and with a heavy, rough harrow, tear up the knolls or shave them off with a plow, throwing the turf bottom up over some rocky hollow, tear up any roots, stumps or spots of moss; rake up the leaves, cut stunted trees close to the ground, scatter the seed and fertilizer, and as you go on so, it will be done as far as you go. This will give you a chance, during the year, to do a great deal, but the cattle will injure it if it is in the open pasture, and they are let in there. Still another method is to fence off half, or a part of the field, and let the cattle have that and fence in a corresponding breadth of some pasture most convenient and appropriate, and work it for crops, allowing a liberal supply of manure. If not too far from the house, build cheap hog pens, and put half a dozen shoats in a small yard connected with it—plant beets, sow peas, turnips and some fodder corn, and feed them in the yard supplying them plentifully with leaves for a nest, and muck if it can be got. This will give you more dressing right on the ground, and save hauling so far. Or a flock of sheep can take the place of hogs if thought best, but whatever stock is put there it must be fed extra besides what is

grown upon the land. Many advise putting sheep into a run-down pasture to fetch it up, there is surely some conceivable argument in favor of this, that is the supposition they will forage on the woods and leave their droppings on the cleared parts, which is contrary to the facts. I think they will be more likely to reverse the thing—feed down what little grass they can find in the green places and clefts of the rocks early in the morning, and return to the woods to digest and discharge it. Any man who puts a flock of sheep into such a pasture, will be convinced in a few years of the truth of the adage from nothing, nothing comes, and find himself in position of the boy who went whaling. At the end of three years the captain settled thus with him: "0's an 0, and 2's a 2; not a cent coming to you."

I will ask you to closely observe through the season, in regard to the various plants and trees named to you, as to their time of flowering, the preference of the bees for them, the amount of honey and its quality, so far as you can, from the different species, and carefully note all down that you may correct any misstatements I have made, and have a more accurate knowledge in the future. This plan will tend to make us all more observing and more successful in our fascinating employment. Above all let us keep one fixed rule constantly in mind, never to be so selfish as to hide any light we may have. Let us constantly seek more light and knowledge, and be as ready to impart it to our bee-keeping brothers, as we are to ask it of them. The most humble member of our fraternity may, by honest endeavor, become the most useful of us all, a bright and shining light in the firmament of the apiarists. That we all strive earnestly, honestly, and unselfishly in this cause is my earnest wish.

Frost Bitten Bees.

W. H. SHIRLEY.

A queer heading for an article on bees I hear some one saying. Wait! let me explain a little. Stimulative feeding in the spring to induce rapid breeding, is, I believe, advocated in all bee books and by many writers. That idea cost me quite a little item, in the way of dead brood, 5 years ago. The same thing occurring again this morning (on a smaller scale—one hive only), put me in mind of old times.

I always winter the bees out of doors, with chaff protection; I have found it the best, so far. I unpack them generally from April 20 to May 10. I have unpacked only 14 this year. At the time of this writing, 4 years ago, we unpacked them early. Bees were in good condition, except that quite a number lacked stores. Here was a chance to try stimulative feeding. As the weather was warm (about 50° most of the time), things moved off nicely; and brood-rearing increased rapidly. We were having

visions of early swarms, and had already divided 5 colonies (dividing for increase, and I have quarreled since that time too). But, alas! the mercury dropped down to freezing; and 2 or 3 frosts followed. The bees had to contract their cluster in order to keep warm. All around them were patches of dead brood; enough to double their numbers.

Stimulative feeding, and I had a quarrel then and there, and never made up, until this spring. Our new way of wintering gives a chance to examine the bees often, with little trouble. We could feed them when the mercury was down to freezing, with ease, and thought we would try stimulative feeding again. Success crowned our second trial, except the one colony spoken of above. On the 15th, we commenced to unpack, as the weather was promising; on the 21st the mercury went down to the freezing point again, and the old story of dead brood in one hive, prompted us to write our little experience in stimulative spring feeding.

The bees in the one colony becoming discouraged, killed their queen, thinking, perhaps, that a young queen would bring warm weather and a "honey shower."

I am in favor of stimulative feeding now, but I want protection from sudden changes in the weather.

Glenwood, Mich., May 22, 1883.

Mahoning Valley, O., Convention.

The quarterly meeting of the Mahoning Valley Bee-Keepers' Association was held at Berlin, May 28.

The attendance was good, the display of apianian appliances first-class, and the basket picnic dinner was enjoyed by all.

The forenoon session was called to order by the president, Mr. Laundus Carson. The minutes of last meeting were approved. The chair appointed the following committee on apianian fixtures on exhibition: Mr. Page, Mr. Hall and Mr. H. A. Simons.

One of the most interesting features was the question box.

"Is it possible for an Italian queen to fertilize by a black drone?" Mr. Carson said, "I believe that all the different breeds of bees will mix more or less."

"What is the cause of my queens getting balled at the entrance of the hive?" I lost several this spring; I found them dead on the floor of the hive." Mr. Simons thought it a weak colony, virtually starved out. Mr. Carson said, "I got some queens of Mr. Heddon, and lost some of them by getting balled. By a close examination I found them with insufficient food." Mr. Hall said, "It only happens in weak colonies where they have more brood than they can support."

"What is the cause of spring dwindling?" Mr. Carson said, "the Italian bees are more venturesome in cold weather, and perish by cold." Mr. Simon said, "the black bees, with me, are more venturesome than the Italians."

"Will handling bees in the spring materially injure them?" It was thought to be a matter of how rough they were handled.

"Will bees swarm in the spring if they have plenty of honey?" It was thought they would when the hives became full of young bees.

Mr. Simon said, "he thought one cause of dwindling was a lack of young bees to take the place of the old ones in the spring, and would advise breeding as late as possible in the fall. I winter out of doors. I use as young queens as possible for late fall breeding. After the bloom is gone, I feed melted sugar in the hives. This spring I noticed a dwindling of my bees; the cause being the lack of young bees."

Mr. Kinney said, "I have had queens which laid eggs and the workers destroyed them. What is the cause?"

"Are Italian bees longer lived than the black bees?" Mr. Carson said, "I do not know. It is a fact that the black bees are short lived in the spring."

"What sized frames would you advise to get the most honey from, long or short frames?" There was a difference of opinion. Mr. Simon used the long frame, and thinks it preferable. Mr. Carson uses the Union frame, and is well pleased with it.

"The best way to preserve empty combs?" Mr. Carson said, "I clean out my hives and hang them in such a way that mice cannot get at them."

Mr. Simon said, "I keep mine in my hive, under a shed, when it is cool." Mr. Carson said, "if worms get into them, fumigate with brimstone, not too strong."

"Will the drones produced by fertile workers on virgin queens perform the office of drones?" Mr. Simon said "I prefer young queens fertilized by a good drone."

"How is the best way to get rid of fertile worker bees?" Mr. — said, "I unite them with a good strong nucleus. Mr. Simon said, "I take the hives that have fertile workers and shake them on the ground, and the fertile workers never crawl back."

"Will it pay to put on sections for the bees to draw out foundations for apple bloom?" Mr. Hall said, "yes." Mr. Winnery thought that if the body of the hives is full of honey it would pay.

"Which is the most profitable to produce, comb or extracted honey?" Mr. Carson said, "extracted."

"Do you prefer drones from the parent colony for a cross?" I think it would be preferable.

"A queen from a pure Italian mother, that meets with a black drone, what will her drones be?" Mr. Page said, "they are his best workers, and are, as a general thing, less quarrelsome." Mr. Hall says, "I wish to breed from the best, let the breed be what it may. I should cross with those drones whose record is good."

"Do bees ever swarm on apple bloom?" Mr. W. said, "I have known of such instances, but do not think it advisable." Mr. H. said, "I

would build up weak colonies by giving them a few sections of brood."

Committee report: We find placed on exhibition the following: Mr. Eadler, a novice extractor, also a new hive which attracted considerable attention. Mr. George King, a Simplicity hive. Mr. L. Carson, a Union hive, a combination of several.

The matter of where and when to hold our next meeting came up for action. It was the unanimous voice of the meeting to hold our meetings at different points in the Mahoning Valley.

Adjourned to meet at Newton Falls on the third Saturday of August, 1883.

E. W. TURNER, Sec.

For the American Bee Journal.

Shall Separators be Used?

F. I. SAGE.

I noticed by the BEE JOURNAL (page 263) that Mr. T. E. Turner confesses that he is becoming "so insane" as to dispense with the use of separators. I consider it pretty good evidence that he has become insane on this subject, and as he admits it, we will take it for granted that such is a fact. But, really, I hope he will not induce New York State bee-keepers to adopt this plan of securing surplus honey. The bee-keepers of New York have the reputation of securing their comb honey in the very best shape for market, and all use separators, except, perhaps, a few who are away behind the times. Of the 50 tons of York State comb honey I have handled during the past season, not a single lot have I bought except where separators have been used; nor would I buy any such, unless at a discount. Every pound of honey I buy must be secured by the use of separators, and every section must be glassed, except the small amount of one-pound sections I use—those should not be glassed.

Mr. Turner says glassing sections are too expensive to the producer; this remark will make some of our York State producers "smile." I always supposed this glassing was the most profitable part of bee-keeping; to be sure, it is some work to glass sections enough to use up one or two tons of glass, but I guess the bee-keeper works many hours for less pay than he gets for glassing his honey. We know it is nonsense to say it does not pay the producer to glass his honey, but whether it does pay or not, our more-advanced bee-keepers, those that get their honey in the most desirable shape and secure the highest price, know it must be glassed for our Eastern trade. I have had Michigan, Illinois and Missouri honey, which was secured without the use of separators, and hence, could not be glassed, but I want no more of it. Although the quality was all right, the style of putting it up was not satisfactory to the consumer, the merchant, or the honey dealer. I could go on, and lengthen out this article, by giving various reasons why this is so, with our Eastern trade, but take

it for granted that New York State bee-keepers are too shrewd, and too far advanced in their profession, to dispense with the use of separators and glass, in order to secure their honey in the most remarkable and profitable shape.

Wethersfield, Conn., May 28, 1883.

Read before Central Michigan Convention.

Cellar vs. the Chaff Hive.

J. T. MATTHEWS.

Among the many ways of wintering bees, which are adopted generally by the people of this country, but two are worthy of notice. These are "cellar wintering," and "chaff hive wintering," the other, leaving the bees out of doors, to "come through" as best they may, is not worthy of mention, for the simple reason that it does not pay.

We have then a single hand-to-hand combat—cellar vs. chaff hive. The question we are trying to decide is, "How to winter bees the cheapest, and have them come out healthy and ready for work in the spring." "Things seen are mightier than things heard." I can do no better than to give a retrospective view of some things brought to my notice within the past year, at the College apiary.

On the 5th of last October, we completed our preparation of the bees for winter. We had 17 colonies of Syrians put up for winter as described by Prof. A. J. Cook, each colony occupying 8 combs of honey, or about 1 cubic foot of space; each colony had about 30 pounds of honey, and from all hives, except one, pollen was carefully excluded, in looking them over. All hives alike had a sack, made for the purpose, filled with very dry sawdust over them, to absorb moisture from the hive and to assist in keeping out the cold in the fall and spring. Four were chaff hives to be left out of doors through the winter, and these, in addition to the sacks before referred to, had sacks extending so as to fill the entire space between the division-board and the end of the hive, thus surrounding the bees on all sides by cushions of chaff. The bottoms were protected by keeping the snow banked under them. Our chaff hives were complete.

On the 14th of November, all the hives were carefully weighed, and the weight of each set opposite to its respective number. On the same day, ten of our common hives (*i.e.* single-walled hives holding 18 frames) and three chaff hives were carefully removed to the cellar. The object of chaff hives in the cellar was to test chaff hives on an equal footing with single-walled hives, to see the effect upon "spring dwindling." The temperature of the cellar, for the winter, ranged from 38° to 42° F. Of the temperature outside you can judge for yourself; suffice it to say it was very cold.

On the 5th of April we returned to our old friends, after an absence of 142 days, and find them as familiar as ever. To complete our experi-

ment, we commenced by weighing the outdoor chaff hives (four in number), and found an aggregate loss of 58 pounds, or an average loss of $14\frac{1}{2}$ pounds to the colony. One colony was dead, and, as one standing by remarked, they died "in the midst of plenty," for they were dead, clustered on frames at one end of the hive, and the honey was gone from those frames, but the frames at the other end of the hive had plenty of honey. The theory is that they became so cold that they could not change their cluster, and they froze to death.

The 13 colonies came from the cellar with a loss of but 56 pounds, or an average of $4\frac{1}{3}$ pounds to the colony. The greatest amount of loss, in any colony in normal conditions, in the cellar, was 6 pounds, and the least amount, 1 pound.

One colony, which was put up for the cellar with the usual amount (30 pounds) of honey, was found dead, and their honey entirely gone, the weight showing a loss of only 10 pounds. We cannot account for this, except to say that they must have been robbed last fall, after giving them their winter supply of honey, before removing them to the cellar in November.

The colony in which the pollen was left had very badly dwindled. Their queen being dead, they were united with another colony. The colonies wintered in the cellar, with two exceptions, (the one containing pollen and the one supposed to have been robbed in October), show very little loss in numbers, by the dead bees found in the hives. In fact, in looking them over, we find many of them apparently as strong as they were last October, while those wintered in chaff hives out of doors (judging from the same source of information) are very weak indeed.

On examining the bees, a few days after removing them for the cellar (April 7), we find eggs in nearly every hive, showing that they are in first-class condition, and will have a full force ready for work when the flowers come; and we think from the general appearance of the bees, that (leaving out the two principal points in favor of cellar wintering: namely, safety and amount of honey consumed during the winter) the bees which have been wintered in the cellar, are in better condition to go to work this spring, than those wintered in chaff hives.

We often hear the objection raised to cellars that they leave the bees in poor condition to stand the changes of spring, but we candidly believe that the fault is rather to be found with the condition of the cellar or the method of treatment in the spring, than with the method of preparing for wintering.

We would conclude then by saying that cellar wintering seems to us to be, at least, the most economic way to winter bees. We believe it, for three reasons: First, it is safer; secondly, it saves honey; and third, it leaves the bees in better condition in the spring.

Michigan Agricultural College.

For the American Bee Journal.

Old and New Rhymes.

EUGENE SECOR.

A swarm of bees in May, is worth a ton of hay.
A swarm of bees in June, is worth a silver spoon.
A swarm of bees in July, isn't worth a fly.

That's the way the rhyme ran, in the days of our boyhood, among the hills of eastern New York. These old sayings, like some of the weather-wise prophecies of a later period, may be of more value in the region where they originated, than when transplanted into this continental prairie soil. At least I thought so, the other day, when the first swarm of bees issued in May.

A ton of hay is worth, in this land of plenty, about \$2.50, while an early swarm of bees ought to yield as much profit as a cow worth \$30. The latter part of the "saw" is as far from the truth as the first. A swarm in July will often fill its hive in 2 weeks, and store a large surplus for its proprietor. August swarms, which did not elicit even a passing notice from the ancient rhymers, will make a hive feel like a chunk of lead when you attempt to move it in the fall. I think in some cases a September swarm might gather honey enough to winter on.

We need a revised edition of those old "sayings," to meet the new conditions of things—at least here in Iowa. If I could grind out rhymes, I would attempt the work myself. I would make it read something like this:

A swarm of bees in May is a "hip, hip, hooray!"—
(in Iowa).

A swarm of bees in June, is in the same tune,—
(in Iowa).

A swarm of bees in July, you needn't be afraid to
try,—(in Iowa).

An August swarm, as the weather is warm,
is all O. K.—don't fool it away,—(in Iowa).

A swarm of bees in September is rare,
But even that can be saved with care,—(in Iowa).

Warm weather has been slow in coming this spring. Only on a very few days has the thermometer indicated above 60°. There has been no frost to damage fruit in this part of the State. Everything is coming along finely, except corn, which was planted late. We have had an abundance of fruit bloom, and white clover is just beginning to blossom. We anticipate a prosperous year.

Forest City, Iowa, June 2, 1883.

For the American Bee Journal.

Italian and Hybrid Bees.

J. O. SHEARMAN.

On page 236, of the BEE JOURNAL, I notice Mr. Hutchinson's question in regard to best hybrids, etc. That reminds me of some of my own experience, which, I think, it would worth while to make known, at this time, as it may throw a little more light on the subject under inquiry. Some may incline to ridicule "Heddon's hybrids" as being no better than all others, but there certainly is a great difference in hybrid bees.

When I first started in keeping bees as a business, I used to wonder at so many people (and those who seemed to be posted, too) who spoke and wrote about the black bees being so much crosser than Italians, while I had large brown bees (called blacks) that were so quiet and easily handled that I opened the hives without smoker or protection of any sort, and when I got my first Italians, I found they were quicker in their movements, and more liable to sting upon slight provocation than those I had before. These brown bees were excellent breeders and workers also. I increased one colony to five, and had a fair surplus too, from four of them.

But two years ago this spring I found out the difference between brown and black bees. We all have in mind that severe winter and spring. I lost over 60 colonies, and to help fill up my empty combs, soon enough to be able to obtain some surplus, I bought 20 colonies (19 of them blacks), and they were black too, black as an old boot, and as cross as a setting hen. I left them at a neighbor's, $1\frac{1}{2}$ miles away from home, so as not to mix with my Italians. I then Italianized what I did not trade off. Years previously I had tried different strains of Italians, mostly light ones, but they would swarm when I tried to crowd them into the honey boxes, while my old brown bees would fill a set of boxes, then notify me they wanted more room, and take what I gave them in a contented sort of a way, and "stick to their knitting." Well, in looking over the papers one spring, I noticed that Heddon had been Italianized, so I sent to him for a colony of dark Italians, requesting him to send me one of the old queens he had received from Mr. Oatman, if he had them booked, and I believe he sent it, for though she did her work completely that season, she played out the next; but not until she had supplied me with a race of bees that excelled anything I had yet tried, for they would go up freely into the boxes and did generally fill all, or nearly all the room I gave them, before swarming, unless crowded in the brood-chamber. And, I could put off swarming by giving more room in the body of the hive, at the same time giving more surplus room, in the same way I had previously practiced with my brown bees.

Now, I come to the hybrid point of the matter. I crossed some of the young queens with the drones of the brown bees, and they produced such good bees for work, that I have never got rid of them all yet. Some of the best of those dark Italians survived the hard winter of two years ago, and I was able to run part of them through last season even, without swarming at all, with a good surplus, and they were always strong in bees.

My hobby has been, and is, to run for surplus, without much increase, to avoid the impression that these bees would not breed fast enough for profit. I will state that I had one of them (two years ago) fill two sets of brood comb, at the same time keeping both well supplied with brood; but I

consider that bad practice, as a queen soon wears out with such management.

In this connection (though off of the subject) I will say that I am convinced I have had a queen do good business through a whole season when she was 5 years old.

Last year (1882) I had several colonies of those first-class hybrids (Italian queens fertilized by brown drones), and they fairly took the lead of anything I had, for surplus, and breeding at the same time. They had 11 brood frames, 8x20 inches, and 75 pounds of surplus room in the height of the season, and all full of bees and work.

New Richmond, Mich.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Use of a Honey Board.

Mr. Heddon: in tiering up cases, in your hive, do you use a honey board between the first and second cases? Please answer in the BEE JOURNAL.

R. M. DENHAM.

St. Clairsville, O.

ANSWER.—We do not. There is no need of any there. Between the brood frames and first case is the place where bracing and consequent daubing occurs.

Honey Register.

Mr. Heddon: please explain how to use your honey register.

IRENEUS M. FOOTE.

Creston, Iowa.

ANSWER.—The following represents our surplus honey register, and it saves us more than \$25 worth of time annually.

29	30	31	1	2	3	4	Renewed.
28						5	
27						6	
26						7	
25	*					8	3-4 * 1-4
24						9	
23						10	
22						11	
21						12	
20	19	18	17	16	15	14	13 1-2

The dial plan was taken from the Root queen register. We drive a pin into each of the stars just over the tapering part, or about $\frac{1}{2}$ inch. Use the cheap, soft, No. 2 pins, which cost 5 cents per paper; they are better than the higher priced pins. To drive them straight, we use a little square block, with a crease cut square across it, which the pin lays in while being driven. Now, bend the pin to a right angle, and a dial is formed. We use two styles of paper, one of

thin white writing, which we paste on the north back corner of the super, and one of manila straw-colored tag board, which we tack on. I use and prefer the paste plan. Now, suppose you put on a case or super, either for comb or extracting. If you do so on June 2, put the left hand pin at "2," the right hand at "R." in the word "Renewed." Now, if you look at this super to see how business is developing, and find no commencement made on June 6, set the left pin at "6," and the right one at "D." "R" and "D" both denote an empty super, but "R." that it has not been examined since put on; "D." that it has one or more times.

On the "12" you find it $\frac{1}{4}$ full; put the left pin at "12" and right one at "1." If $\frac{1}{3}$ between "1" and "12," and thus for any proportion your eye tells you is correct, from just started to nearly finished. With our tiering up system, we use one on every case, and you see we can tell just how matters stand, and just where an hour's work is needed at once.

We need no month dial, as he whose memory is a month "off," should not try to manage an apiary. We know just how practical and useful these registers are, by how we chafe when we come to one that we made the error of not tagging with the register.

Our style of arranging the figures in the dial is much better than Mr. Root's; the square form with all the figures upright, shows off at a glance a long way off.

SELECTIONS FROM OUR LETTER BOX

Bees and the White Clover.

We have rather a bad season for our pets; cold and raining some now. Near me, we have a great crop of white clover, but hardly a bee have I seen on it. Dr. N. P. Allen says, in the last BEE JOURNAL, that the bees are working on white clover in his neighborhood. I walked through a large field of beautiful clover, and I saw only two or three bees on it. We have fields literally white with it; and near us hundreds of acres of it. I have had only one swarm as yet, and that went back to the parent hive.

G. W. ASHBY.

Valley Station, Ky., June 3, 1883.

Honey Prospect in New York.

Up to this date bees have had a cold, windy spring; and where they were not in good condition when set out, they have "gone up." I have

lost but one colony since they were set out, and that was deserted when I was away. Bees are in fine condition, for quite a large number of them are preparing to swarm, and, if the weather should be favorable for a week, general swarming may be looked for. There is every prospect for a large crop of honey, in this locality, to those that have bees; for the fields are covered with clover, which will begin to bloom about the middle of this month. Basswood is budding as full as I ever saw it, and, with favorable weather, bees must have a lively time. It has been exceedingly wet ever since the snow disappeared in this locality, until the last 4 days, which have been warm and pleasant.

IRA BARBER.

De Kalb Junc., N. Y., June 4, 1883.

Cheering News from Kentucky.

Our Convention on the 2d inst., was a grand success—a fine turn-out of practical bee men. Our white clover harvest is immense, and the largest crop of honey will be gathered in Kentucky that we ever harvested; the clover fields look as white as snow, and bee men are worked down, and are in clover.

N. P. ALLEN.

Smith's Grove, Ky., June 4, 1883.

Texas Honey Crop.

The honey crop in this district promises badly. So far, there is little or none coming in, and colonies are dwindling very much. I have been feeding mine, and am doing so now; and, instead of dividing, it becomes a question of uniting weak colonies. With no honey coming in, queens stop laying, and colonies are fast getting in such a condition that, if there was to come a honey flow, the bees could not fairly gather it. Last year there was a good crop; this year appears to be an "off" year.

R. J. KENDALL.

Austin, Texas, June 3, 1883.

Cross Bees.

Why are my Italian bees so very cross this spring? One colony gave a swarm on the 9th of this month, which went back to the old stand without clustering. The weather set in cold and rainy, and they did not come out again until the 17th. They clustered on a little willow, close to the ground, so that I could not saw it off. I set the hive close up to the cluster, and took a turkey wing and commenced to brush them on the alighting board. I had only made one stroke of the brush, when about a quart went into the hive, and about two quarts into my face and hair. You may judge the result; as many stung me as could get a chance. A neighbor of mine had been wanting for several days to see the bees swarm, as it was a new thing to him. He was standing close by—they made a dive for him, and gave him a fearful stinging; he had a little dog with him, and the bees gave them both a fight. My neighbor ran away and the dog followed; both were covered with bees. He ran into a milk house, and so did the dog. Such a fight I never witnessed before. The

few I got in front of the hive induced the balance to go in all right. I was waiting for them to quiet down, so as to move the hive where I wanted it to remain. All at once they came rushing out and went back to their old stand again. It commenced to rain that evening, and kept cold until Sunday; about noon the sun came out and out came the bees; they soon clustered on the bottom of a little apple tree, down close to the ground, with a good many on the ground and in the grass. I took a dipper and my turkey wing and commenced business again, but was prepared for them that time. I made a veil and had it on, and a pair of gloves. So I got them all in, without receiving a sting, but I should have got a great many, except for the protection. They have been in the hive 3 days without a fly. The weather has been cold and rainy ever since; only stopping a little while at night to get a good start for the next day. I would have had 4 or 5 swarms this month, if the weather had been favorable. I have fed the new swarm to-day; they keep up a constant roar, as though all was right. I have heard a queen piping in the old hive ever since the swarm came out, but only hear one. Is that any indication of swarming soon again? I am a beginner in the business, and want to learn all I can. I have read Quinby's and Cook's Manuals, and, with the aid of the BEE JOURNAL, I think I can get through.

R. A. ROSSER.
Nelsonville, O., May 23, 1883.

[We expect the bees were hybrids, notwithstanding you call them Italians. Several have reported similar results when hiving hybrids under certain conditions. You should have had a good smoker at hand, and, by its use, saved such a calamity as the one you have described above. The unpropitious weather which had kept them prisoners so long, with no chance to be gathering honey, had doubtless made them angry, and ready to fight at the least provocation. Some bees seriously object to being brushed even with a turkey wing, and, when they are thus excited, will show their anger by acting just as your bees have done.]

The piping of the queen, which you mention, indicates that a "second swarm" is determined upon. Upon this decision, the bees prevent the first queen that issues from killing the rest, and place a strong guard over their cells, and when she comes with murderous intent, she is repulsed by the bees. This offends her majesty who utters these shrill notes of anger. If this piping is not heard within a few days after the first swarm issues, it is because the queen has no rivals, and swarming may be said to be over with that colony for the season.—ED.]

Bees Near a Roadway.

Please answer the following questions through the BEE JOURNAL:

1. Will the law compel me to move hives of bees that are standing near a line fence.

2. Will the law compel me to pay damages, if my bees sting horses that are driven on the opposite side of the fence.

I have had my bees where they now stand for the past 13 years, and without any trouble. But, this year, a drive-way has been made close to the fence, for the purpose of getting to a back lot. The fence is a tight board fence between 6 and 7 feet high. Neighbors also use this drive-way to work land on another farm. I am doing all that I can to control the bees, having moved some of the crosses from near the fence a distance of two miles.

JAS. B. TUMBER.
Warren's Corners, N. Y.

[Not being a judge, the law points we cannot pass upon, but if we owned the bees, and had any land elsewhere, they would be moved as soon as possible, so as not to have them annoyed and "worked up" all the time by passing teams, horses that are sweating, etc.—ED.]

Fully Appreciated.

The Weekly BEE JOURNAL is, to me, worth all the other bee papers put together; may you, Mr. Editor, live to see its full worth appreciated, not only at home here, but in thousands of foreign homes where the "busy bee" is kept, and where every flower is fanned by its silvery wings.

D. W. FLETCHER.
Lansingville, N. Y., May 21, 1883.

Experience of My Friend and I.

Perhaps the readers of the BEE JOURNAL would like to hear something of a friend of mine, living in the same house, who being fond of bee-culture, in the old country, continued in the new world to keep bees; not so much to make a trade of it, as to render his pastime pleasant. Accordingly the BEE JOURNAL never comes into his hands without being perused with great interest, from the beginning to the end. He tells me, that he received much information from it, especially about feeding and wintering. Last winter, making use of the hints given in the BEE JOURNAL, he succeeded in wintering his bees with but an insignificant loss of one weak colony, which he received too late in the fall to make a trial in feeding. The bees then clustered all on one side, leaving the other frame yet containing honey enough untouched, and finally died.

1. Why did the bees all gather on one side, and not move to the combs filled with honey?

My friend covered the hives, in the beginning of winter, partly with straw mats, and partly with blankets; around them he constructed a wall of chaff, a few inches in width. The

hives, having straw mats kept dry; the others not, for out of the inlet often water was flowing. I concluded that the moisture inside was absorbed by the straw mats, but not by the blankets. On the 19th of May, in one of the hives, there was much noise, and many of the bees clustered all in one pile outside of the hive. Now, I thought, they would swarm. My friend laughed first at me, but in the end he prepared a hive for any eventuality. Yet the cold weather from the 20th to the 23d checked them. We had a north wind storm and rain, with snow, and it was very cold; fires were started in the stoves once more.

2. Do bees really sometimes swarm in the end of May?

A Bingham smoker gave full satisfaction to my friend, who was overjoyed with it and the Bingham & Hetherington honey knife. Our bees are very "gentle and good-natured;" they never sting me, though I watch them closely in their busy movements. Once, my friend was in danger. One swarm of bees, which he had received from a neighbor, and which were not attended to properly, was to be transferred into a new hive. But the frames were all connected by combs, which the bees had constructed, making the replacing difficult. My friend, nevertheless, was determined to separate them. In cutting the connected combs asunder, he destroyed some brood; then there was humming about the ears. Hence, my friend received a few stings. Not so I. As we could not use the smoker—there was straw, etc., near—we smoked tobacco, and this so much, as to make us quite dizzy. Alas! never shall we do that again; we shall certainly use the Bingham smoker.

FRANK.
Seneca Co., O., May 23, 1883.

[1. The bees clustered on one side in order to utilize the heat of the cluster; then, as they were few in numbers, it became too cold for them to go to the honey, and hence starved, with "plenty" close to them, but out of their reach.]

2. Yes; if the weather is propitious, and they are strong in numbers.—ED.]

The "Big Damp," by the Floods.

We have had some very valuable yet unprofitable experience during the late "big damp" in the Ohio Valley, by the washing away of almost all the bees in the neighborhood. Several boxes and hives were caught during the flood, though quite cold weather, with bees clustered at the edges of comb out of the water, wet and chilled, but with little care they were saved. One man saved 2 out of 8 colonies, after they had been floating in the water four days. Another saved 8 out of 18, after floating six days, and only kept from floating away entirely by houses and high fences surrounding them; some were right side up, some bottom up, and others on their sides; yet almost all these are now in good condition, having built up rapidly on our abundant early spring fruit-bloom. Some of

them I have transferred for the parties to get rid of the badly soiled combs, the cells of which were well filled with mud and sand. My bees were saved by first placing them on the roof of the bee house, which subsequently floated away, but not until after I had transferred my bees to the roof of my office, where I saved them all, in good condition. All colonies taken from the water were more or less damaged, by depletion in numbers, and soiling of combs. Bees in Southern Ohio, above high water mark, and those kept out of the water, are in excellent condition. They wintered well, coming through, well stocked in bees and capped brood, and have built up fast during the spring, on early fruit bloom, which was very abundant. Now we have a most flattering prospect of white clover blossoms, scattered with unsparing hand by a wise, over-ruling Providence. Our honey harvest, this year, cannot be other than excellent. I look for my BEE JOURNAL as for my breakfast, with a keen appetite.

R. A. MOLLYNEAUX.

New Richmond, O., June 1, 1883.

Peculiar Season for Bees.

The past month has been the worst May I have ever known for bees, and as a consequence, bees are in poor condition. Mine are in fully as bad shape, if not worse, than they were last year at this time, and vegetation is at least a week later than then; and we thought last year was as bad as a season could be. The season will have to be a very peculiar one from this time on, to allow us to obtain an average crop of honey.

O. O. POPPLETON.

Williamstown, Iowa, June 1, 1883.

Cold and Backward Season.

The season is very cold and backward here. We had another frost last night. Fruit is much injured. Fruit and early forest bloom have amounted to almost nothing for the bees, on account of continual cold and rain. Feeding is now the rule, in my apiary, to ward off starvation, though the hives contained very ample stores in the fall. The colonies, however, are nearly all very strong; most of them having clustered outside. Have already had 4 swarms. Winter and spring loss is less than 10 per cent. The season is about two weeks late.

H. D. BURRELL.

Bangor, Mich., June 1, 1883.

"Bees and Honey," for Beginners.

The majority of those who buy bees of me, depend upon me to get them a reference book. "Bees and Honey" more nearly "fills the bill" than any work I know of, especially for those who buy that they may supply their own family with honey, and not to make a business of it. It combines cheapness, quality and quantity in the right proportions. To one who has purchased several colonies, I usually have donated a copy of it.

Lincoln, Neb. G. M. HAWLEY.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5. or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Do not send coins in a letter. It is dangerous and increases the postage unnecessarily. Always send postage stamps, for fractions of a dollar, and, if you can get them—one-cent stamps; if not, any denomination of postage stamps will do.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
" 100 colonies (220 pages)..... 1 50
" 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Special Notice.—We will, hereafter, supply the Weekly BEE JOURNAL for one year, and the seventh edition of Prof. Cook's Manual of the Apiary, bound in fine cloth, for \$2.75, or the Monthly Bee Journal, and the Manual in cloth for \$1.75. As this offer will soon be withdrawn, those who desire it should send for the book *at once*.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

Sample Copies of the AMERICAN BEE JOURNAL will be sent *free* to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

Bingham Smoker Corner.

Large Smokers need wide shields. Bingham's have them, and springs that do not rust and break, and bellows that sparks and smoke do not enter. The Conqueror has all improvements made to date, and a 3x7 inch stove, and 5x7 inch bellows. Sent post-paid for \$1.75. Address,

BINGHAM & HETHERINGTON,
Abronia, Mich.

All Excelling. — Messrs. Bingham & Hetherington, Dear Sirs:—I am now selling your Smokers almost exclusively. You are excelling yourselves in smokers all the time.

Respectfully, J. G. TAYLOR.
Austin, Texas, May 10, 1883.

Cyprians Conquered.

All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am "boss." Bingham's "Conqueror Smoker" did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham.

G. M. DOOLITTLE.
Borodino, N. Y., Aug. 15, 1882.

During the following three months, Bingham Smokers will be sent post-paid, per mail, on receipt of the following prices:

The "Doctor" (wide shield)—3½ in. fire tube, \$2.00
The Conqueror (wide shield)—3 in. fire tube, 1.75
Large (wide shield)—2½ in. fire tube, 1.50
Extra (wide shield)—2 in. fire tube, 1.25
Plain (nar. shield)—2 in. fire tube, 1.00
Little Wonder (nar. shield)—1½ in. fire tube, .65
Bingham & Hetherington Uncapping Knife, 1.15

With thanks for letters of encouragement, and the absence of complaining ones, we tender to our thirty-five thousand patrons our best wishes.

Very Respectfully Yours,

BINGHAM & HETHERINGTON.
Abronia, Mich., June 1, 1883.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Do not let your numbers of the BEE JOURNAL for 1882 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

May we ask you, dear reader, to speak a good word for the BEE JOURNAL to neighbors who keep bees, and send on at least one new subscription with your own? Our premium, "Bees and Honey," in cloth, for one new subscriber to the Weekly, or two for the Monthly, besides your own subscription to either edition, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

JUST OUT!

New circular and price of Bees and Queens. Also, STENCILS for bee-keepers' use.

JOS. M. BROOKS,
Columbus, Ind.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL.
Monday, 10 a. m., June 11, 1882.

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY.—The nominal price of extracted is 7c. for dark and 9c. for light—here. The supply is abundant and sales are slow.

BEESWAX.—None in the market.

A. L. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY.—The market for extracted honey is lively, and the demand exceeds the arrivals. Our stock is small and we are in danger of having sold out every day. We pay 7½c. for good honey on arrival, the latter price for choice clover. There is a small demand for comb honey, and prices nominal.

BEESWAX.—Arrivals of beeswax are plentiful. We pay 35c. for a good article on arrival.

CHAS. F. MUTH.

Quotations of Commission Merchants.

NEW YORK.

HONEY.—Best clover in 1-lb. sections (no glass) 22@23c.; in 2-lb. sections (glass) 18@20c. Fair quality, 1 and 2-lb. sections, 17@18c. Extracted, white, in small barrels, 10@11½c.; buckwheat, 8@9c. BEESWAX.—Is more plentiful. Prime yellow sells at 37½@38½c.

H. K. & F. B. THURBER & CO.

CHICAGO.

HONEY.—Prices declining. Holders are anxious to sell, and the prices vary very much.

BEESWAX—35@36c.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY.—Stocks and the demand are both light. More or less difficulty would be experienced in filling a large order for a straight lot.

White comb, 14@17c.; dark to good, 11@13c.; extracted, choice to extra white, 8½@9½c.; dark and candied, 5½@7½c.

BEESWAX—Wholesale, 27@28c.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY.—Strained salable at 7½c.; comb sold in a jobbing way only—old 10@14c. and new 15c.

BEESWAX.—Sold mainly at 33@34c.—latter for prime.

W. T. ANDERSON & CO., 117 N. Main Street.

CLEVELAND.

HONEY.—There is a moderate sale for best white 1-lb. sections at 18c. occasionally 19c. but 2 lbs. are not called for. Extracted is no sale at all.

BEESWAX.—Not offering.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY.—Our market is fairly active. We quote: ½ lb. sections at 30c.; 1 lb. sections, 22@25c.; 2 lb. sections, 20@22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.

BEESWAX.—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatham Street.

NOTICE.

We have just completed the largest and best lot of Smokers ever manufactured. Prices by Mail:

2 inch....Double Blast.....\$1.50
2 "....Single ".....1.00
2½ "....Double ".....1.75
3½ "....Single ".....2.00

Special inducements to those who buy to sell again.

THE BEST BEE BOOK

"Of all the books on bee-keeping, QUINBY'S NEW BEE-KEEPING stands pre-eminently at the head, in my opinion." Sincerely Yours,
April 11, 1883. G. M. DOOLITTLE.

Sent by Mail, Post-paid, for \$1.50.

L. C. ROOT & BRO., Mohawk, N. Y.

1941

DUNHAM COMB FOUNDATION.

Twenty-five lbs. or less, 55c. per lb.; over 25 lbs. 52c. per lb. Extra thin and bright 10 sq. ft. to the lb.) 58c. Wax worked for 10c. per pound.
2445t F. W. HOLMES, Coopersville, Mich.

HOLY LAND QUEENS.

Untested, ready about June 10. Single Queen, in this month, \$1.25; six or more, \$1.00 each; 60 tested Queens, this month.

I. R. GOOD, TULLAHOMA, Coffee Co., TENN.
23A4W

BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS C. NEWMAN.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most honey in its best and most attractive condition.

Appreciative Notices.

A neat and abundantly illustrated hand-book of apiculture.—American Agriculturist, N. Y.

Its chapter on marketing honey is worth many times its cost.—Citizen, Pulaski, Tenn.

Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of every beginner with bees.—News, Kenosha, Ill.

Valuable for all who are interested in the care and management of bees.—Dem., Allegan, Mich.

Engravings are fine. Gotten up in the best style, and is cheap at the price.—Farmer, Cleveland, O.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price that has ever come under our notice.—Farmer, Lancaster, Pa.

PRICE—Bound in cloth, 75 cents; in paper-covers, 50 cents, postpaid.

THOMAS C. NEWMAN,

925 W. Madison St., Chicago, Ill.

\$4.00 One Hundred Colonies Bees.

As our store business demands all our time, we have decided to close out our apiary at \$4.00 per colony. Will extract most of our honey, and commence shipping about the 1st of August. Bees in my double wall hive, size of frame, 14x12, with side and top storage for 75 pounds of honey, also 25 3-comb nuclei double wall, takes hive frame, at \$2.00 each. Orders booked and filled in rotation. Send by Registered Letter.

2441t Address, J. E. MOORE, BYRON, N. Y.

E. T. LEWIS & CO., Toledo, Ohio,

Manufacturers of the U. S. STANDARD Honey Extractor (new improvements), and all other Apiarian Supplies. Send for circular. 17A 5Btf

BEE - KEEPERS, before ordering your APIARIAN-SUPPLIES

send for our large illustrated catalogue, sent free to any address.

THE AMERICAN
BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

The Standard Langstroth Frame.

Mr. M. M. Baldrige, St. Charles, Ill., sends us the following for publication in the BEE JOURNAL:

It has been shown on several occasions, by the very best of evidence, that the correct length, outside measure, of the "standard Langstroth frame," is $17\frac{3}{8}$ inches, and not $17\frac{5}{8}$ inches. The evidence is the 3d revised edition of Mr. Langstroth's book; and, I will now add, *all subsequent editions of said book*. As an attempt has been made by some to show that Mr. L. has stated somewhere, in print, that the "standard Langstroth frame" is $17\frac{5}{8}$ inches long, outside measure, I will at present simply deny the *truth* of such an assertion. And, while I am on this subject, I may as well also deny that Mr. L. has given, "in a prominent periodical," any *reasons* (?) for changing the outside length of the standard Langstroth frame from $17\frac{3}{8}$ to $17\frac{5}{8}$ inches. Now, if any one thinks otherwise, please come right along with the *proof*.

In an editorial note on page 272, we stated that "Mr. Langstroth had publicly given his sanction to the frame $17\frac{5}{8}$ inches long." And, on page 251, Mr. Alves states that "Mr. Langstroth himself has approved the change to $17\frac{5}{8}$ inches."

As these statements can be so easily *sustained*, and to save any labored arguments, we will here give the *proof*:

In the BEE JOURNAL for December, 1878, page 427, we published an article written by Mr. Baldrige on this subject, in which he says:

"The outside length of the [Langstroth] frame is $17\frac{3}{8}$ inches, instead of $17\frac{5}{8}$ inches, as given by Messrs. Newman and Root. This is an important mistake, as it destroys the interchangeableness of the frames."

Desiring to have Mr. Langstroth decide the point, we sent him an advanced proof sheet of the article, for his decision. His answer was unequivocal, and as follows:

"Mr. Baldrige is in error in supposing that such slight variations as he notices, destroy the interchangeableness of the frames. Considering the accuracy which may be obtained in making the frames stiff and perfectly square, *I prefer the measurements of Messrs. Newman and Root.*"

As before stated, we said "Mr. Langstroth has given his *sanction* to the frame $17\frac{5}{8}$ inches long;" and Mr. Alves asserted that "Mr. L. had himself approved the change." If the quotation given does not "sanction" and "approve" the change, we do not know what language Mr. Langstroth could have used to have *approved* and *sanctioned* it!

Mr. Langstroth's attention was called to the change of $\frac{1}{4}$ inch in the length of his frame, from the figures given in his book, and he promptly endorsed the change, and wrote for publication in the AMERICAN BEE JOURNAL: "I prefer" it.

The arguments *against* the change, and Mr. Baldrige's assertion that it was "an important mistake," because "it destroys the interchangeableness of the frames," were also submitted to Mr. Langstroth, and he immediately wrote the reply for publication in the BEE JOURNAL (vol. 14, page 427), "Mr. Baldrige is in error!"

If this emphatic language of "the author of the book" and "inventor of the frame" does not settle the point—then it cannot be settled; and to further *discuss* the matter is but a *farce*!

The last edition of Mr. Langstroth's book (the fourth) was published about 25 years ago; since then, some have thought that a modification of $\frac{1}{4}$ of an inch in the length of his frame was to be desired, and Mr. L. has publicly endorsed that change. Now, therefore, to ignore this, his latest decision,

made in the light of the *ever-living present*, and to persistently appeal to a book (be it one ever so valuable) a quarter of a century old, and therefore, "behind the times," not even hinting at many of the grandest inventions and improvements inaugurated during the past 25 years, is *unprogressive*! Such a course is something akin to that of going back to the "dark ages of the past," to define the courses and size of the planets, while ignoring the discoveries of more recent astronomers, made in the light of the *present progressive age*!

Salt for the Apiary.

The *Grange Bulletin* has the following advice about the generous use of salt in the apiary:

Use salt freely about your hives. Sprinkle a little water with plenty of salt outside, and in the hives, when the bees are troubled with ants. Good salty brine is of much value in destroying moth eggs about hives. Rock salt is good to make brine of, to prevent foul brood, which sometimes destroy whole apiaries, and is to be much dreaded by the apiarist. It is better to use an ounce of preventive than a pound of cure. Use small troughs for the brine.

Backwardness.—Complaints are now quite numerous about persons not receiving hives, sections and queens after ordering them of many of our most reliable dealers and breeders. The *backward* spring weather has prevented queen rearing, and is a sufficient excuse for not receiving queens. And the *backwardness* of bee-keepers in not ordering hives and sections earlier, is the cause of much inconvenience to them and others. Many rush in orders for such at the same time (some even by telegraph), till the capacity of all supply dealers is exceeded. This should teach a valuable lesson for another season—to get such things early—in time to prevent the possibility of waiting for them.

Bees, Fruit and Flowers in Virginia.

In the Winchester, Va., *Times*, we notice the following concerning Virginia's bee-master, Mr. E. C. Jordan :

"We have received some very fine strawberries from Mr. E. C. Jordan, the proprietor of Jordan's White Sulphur Springs. He regrets that his mammoth variety is not yet ripe, but if they are any larger than the fine ones he sent us, strawberries can no longer be classed among the small fruits. 'In the course of a few days,' he writes us, 'we will have them by the bushel. Come out and see us, our bees, flowers, and strawberries.' Thank you, sir, 'if we know ourselves, and we think we do,' we will be there to see the place so well-known for its beauty, and to partake of its equally famous hospitality."

The editor of the BEE JOURNAL would be delighted to spend a short time at the "White Sulphur Springs," this summer, for recreation, but we fear he cannot be spared from his "desk" and everlasting round of duties. Nothing would give him greater pleasure than to accept of Mr. Jordan's many pressing invitations to spend some time among the

Bees and berries,
Plums and cherries;
Birds and bowers,
Fragrant flowers;
In the sunny,
Vale of honey;
With birds that sing,
At Sulphur Springs,
In "old Virginia!"

When we retire from the tripod, Mr. Jordan may expect us to settle down in that locality—to enjoy "old age" with the birds, bees and flowers of the sunny South—that is the height of our ambition.

Humble-Bees and the Clover.

Prof. C. H. Fernald has written the following article for the *Maine Farmer* on the "Humble or Bumble-bees, their habits and uses," which will be of much interest to many of our readers. The fertilization of flowers, both by these bees as well as by the *Apis Melifica*, or honey bees, and other insects, is a subject of considerable interest to farmers as well as to bee-keepers. Prof. Fernald remarks as follows:

"The Humble-bees, or Bumble-bees as they are sometimes called, are among the largest and most showy of our Maine Hymenoptera, and are extremely useful to the farmers for the work they do in cross fertilizing red clover. It is well known that the flower tube of this plant is so long that few insects have a sufficient length of tongue to reach the nectar in the nectary, and, therefore, it is not often frequented by honey bees and

other nectar-loving Hymenopterous insects. We are, therefore, greatly indebted to the Humble-bees, for their visits to the clover, their great hairy bodies become more or less powdered with the pollen, and when they visit other clover heads their flowers are fertilized by the pollen which the Humble-bees have brought from the flowers previously visited.

It has been claimed, and without doubt correctly, that unless cross fertilization is effected in some way, the clover will run out. Darwin covered 100 flower heads of red clover with a net to keep the insects from them, and not a single seed was developed, but from 100 heads on plants growing outside, which were visited by bees, there were obtained 2,720 seeds. Experiments, of a similar character have been repeatedly performed both in Europe and in this country, and with like results. In all my observations I have scarcely ever seen any other insects visiting red clover than Humble-bees.

These insects are pretty generally distributed over the world, being found in both North and South America, in Europe, Asia and Africa, but not in Australia and New Zealand. It is in northern latitudes that they thrive best, and they even occur in the most northern regions to which man has penetrated.

In Australia there are no native insects adapted to the cross fertilization of red clover, and it has been attempted to introduce Humble-bees into that country for this purpose, but with what results I have not yet learned.

There are four different kinds in a colony of Humble-bees, the large females or queens, the small females, the workers and the males. Only the queen lives over the winter, and she hibernates either in the nest or under fallen leaves, or in some protected place. When the warm days of spring come, these large females, or queens, may be seen flying from place to place, crawling in and out of places, around and under stumps and stones, hunting for some place in which to make their nests.

When one of these queens finds a suitable place, as a deserted nest of a field mouse, or some hole under a stone or stump, she at once collects a small amount of pollen, which she mixes with honey, making a more or less sticky mass which she sticks into the pollen basket on the outside of the hind leg, and in which it is carried to the nest. As soon as a small mass of this food is collected, the queen deposits several eggs in it without order, and without even constructing any cells, but she continues the work of collecting pollen and laying eggs until the first brood emerges. As soon as the eggs hatch, the young begin to eat of the mass of food which surrounds them, thus enlarging their cavity gradually until they reach their full growth as larvae, when they spin a silken wall around themselves, lining the cavity which they have excavated in the pollen mass. The old bees close up these cells with a thin layer of wax, and the young trans-

form into pupae, and in due time change into the perfect stage and cut their way out, when they are ready to assume their duties as workers, small females, males, or queens, according to their individual formation.

In the spring and early summer, only the large females are to be seen abroad on the wing, but the first brood consisting of workers only, as soon as they emerge, at once take upon themselves the work of the nests and the collecting of pollen and honey, while the queens remain in the nests. After this time, only small bees are to be seen visiting the flowers, and these are the workers.

As the queen continues prolific, more workers are added, and the nest is rapidly enlarged. About midsummer, eggs are laid which produce both small females and males. It is supposed that they pair near the end of the season, and as a result, these small females lay eggs from which the queens are developed. It has been proved that all the eggs laid after the first of September, produce the large females or queens, and as the males are still in the nest, the queens are impregnated in the air after the manner of the honey bee. On the approach of cold weather all the Humble-bees die except the queens, of which there are now several in each nest. These queens hibernate during the winter, and in spring they revive to repeat another cycle as described.

Twelve different species of Humble bees belonging to the genus *Bombus*, are known to inhabit New England, and of these I have taken five in Orono.

I am not aware that these insects are in any way injurious, but from the above showing they are of immense value in cross fertilizing plants, and should be protected. Mowing machines and horse rakes destroy their nests when run through them, but this should be avoided when possible.

It is true that they sting upon severe provocation, as when one attempts to destroy their nests, but who wouldn't fight for their own homes and firesides?

Nameless.—It is surprising that any one should be so careless as to forget to give their name when sending money in a letter. We have a bundle of such letters in this office (each one contains money for books or Journals), and, as they have no name signed, it is impossible to fill the orders or communicate with the writers. When we have some clue, either by post mark or post office address given, we usually find out by writing there either to some subscriber, or to the post master—but with these in this bundle we have no clue, and must wait until the writers shall give us their names and addresses. To all we would say—be careful to sign your names, and give your Post-Office, County and State.

Bees in Africa and the Kafirs.

The bees of Africa, especially of the Southern portion, near the Cape of Good Hope, are as much more vicious than the Cyprian bees, as the Cyprians are crosser than the Italians, if we may credit the testimony of a correspondent of the *London Nature*, who relates the experience of himself and his two servants (one a Kafir and the other a colored Malay), which he describes as follows:

I keep two apiaries at a considerable distance from each other, to one of which my gardner, a colored Malay, attends, and to the other a Kafir laborer. At first they were generally stung when passing too near the entrance of a hive, but now they pass and repass with impunity. They work with the bees more frequently than I do, and yet when either of them assists me in his own apiary, he receives more stings than I do. This I ascribe to the gardner's using snuff in his mouth very freely, and to the Kafir's very pronounced odor.

To test the recognition of the bees, I once requested the Malay and the Kafir to change clothes with each other, and wear thick veils over their heads and faces. They did so, and assisted me first in the apiaries to which they were respectively in the habit of attending, with the result that they received no stings, but when either began to work with the bees in the apiary he usually did not attend to, he was so stung about the hands that he had to beat a hasty retreat, while I remained uninjured, although not veiled. The two men are almost of the same size and build, so that if the bees had any power of general recognition, they would probably (as some of the other servants did) have mistaken the one for the other. I can, therefore, only account for the conduct of the bees by the unpleasant, and to them strange, odor. At my request the gardner discontinued the use of snuff in his mouth for some time, and during that time he was not stung more than I was, while working with the bees; but if the Kafir stands before the entrance of an unaccustomed hive, he is remorselessly stung.

I may add that Cape bees are very much more vicious than European ones seem to be, and that, if not skillfully handled, they will unmercifully sting their most familiar friends. On one occasion, a bunch of carrots was left near the gardner's apiary, which so enraged the bees that they stung him and everyone else they came across, and very nearly stung a cow to death at a distance of about a hundred yards from the apiary; and on another occasion a horse, still wet with sweat, trespassed too near a hive, with the result that the whole apiary was in uproar, and some of my children and servants were stung, the chief victim being a Malay girl, who used to apply quantities of scented pomatum to her hair, and who was severely stung on the head.

Mr. Romanes continues his narration thus:

"Again, many instances might be quoted, such as that given by Guerdingus, who allowed a species of wasp, native to Natal, to build in the door-posts of his house, and who observed that, although he often interfered with the nest, he was only once stung, and this by a young wasp; while no Kafir could venture to approach the door, much less pass through it."

It does not appear whether any white stranger was ever stung, and the only inference that could be reasonably drawn from the conduct of the wasps, is, that they disliked the odor of Kafirs, which, as is well-known, is peculiarly disagreeable. If a particular Kafir had been in the habit of passing through the door, the wasps would probably have become accustomed to his scent, in the same way as a colony of bees, upon the testimony of Sir John Lubbock, became accustomed to the scent of eau-de-cologne repeatedly dropped at the entrance of their hive.

Keep the Bees at Work.

There is at present every indication that the honey harvest this year will be very large. Honey-producing plants, trees and shrubs are full of liquid sweetness, and with fair weather the crop will be an exceedingly large one. Mrs. L. Harrison in the *Prairie Farmer* remarks as follows on this and other important subjects:

No one can now tell what the harvest will be, but there is a great growth of white clover, and if the clerk of nature's laboratory works in our favor, we shall secure an abundant harvest, for the workers are many and the fields white. But the watchmen must be faithful and see that every tenant pays his rent; no "loafing" must be allowed, and "hanging out" stopped instantly. Some bees will wax fat, and loaf for weeks, getting ready to swarm, if allowed to do so. There is no need of waxing fat, when they are to be supplied with foundation for their combs.

There should at all times be plenty of surplus room, not too much, but enough to accommodate all the bees. Sometimes bees hang out because there is too little ventilation, or they are too warm. They should be cooled by shading, given more air and surplus room. If all these fail, smoke them in, and if they cluster out again, pour honey on them, stir them up with a spoon, and then run for life, for they will be on the rampage. As a last resort, prepare a hive with frames of comb or foundation, and lift off the surplus boxes on to it, remove the hive and place the prepared hive where the old one stood. All the bees returning from the fields enter this, and the bees on the combs brushed in front of this, together with the

queen. The combs of honey and brood can be given to small colonies.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL,
Monday, 10 a. m., June 18, 1882.

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY.—The nominal price of extracted is 7c. for dark and 8c. for light—here. The supply is abundant and sales are slow.
BEESWAX.—None in the market.
AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY.—The market for extracted honey is lively, and the demand exceeds the arrivals. Our stock is small and we are in danger of having sold out every day. We pay 7c. 10c. for good honey on arrival, the latter price for choice clover. There is a small demand for comb honey, and prices nominal.
BEESWAX.—Arrivals of beeswax are plentiful. We pay 35c. for a good article on arrival.
CHAS. F. MUTH.

Quotations of Commission Merchants.

NEW YORK.

HONEY.—Best clover in 1-lb. sections (no glass) 22c. 23c.; in 2-lb. sections (glass) 18c. 20c. Fair quality, 1 and 2-lb. sections, 17c. 18c. Extracted, white, in small barrels, 10c. 11c.; buckwheat, 8c. 9c.
BEESWAX.—Is more plentiful. Prime yellow sells at 37c. 38c. 40c.
H. K. & F. B. THURBER & CO.

CHICAGO.

HONEY.—Prices declining. Holders are anxious to sell, and the prices vary very much.
BEESWAX.—37c. 38c.
R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY.—Stocks and the demand are both light. More or less difficulty would be experienced in filling a large order for a straight lot.
White comb, 14c. 17c.; dark to go d. 11c. 13c.; extracted, choice to extra white, 8c. 9c. 9c.; dark and candied, 5c. 7c.
BEESWAX.—Wholesale, 27c. 28c.
STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY.—Strained salable at 7c. 7c. 7c.; comb sold in a jobbing way only—old 10c. 14c. and new 15c.
BEESWAX.—Sold mainly at 33c. 34c.—latter for prime.
W. T. ANDERSON & CO., 117 N. Main Street.

CLEVELAND.

HONEY.—There is a moderate sale for best white 1-lb. sections at 18c. occasionally 19c. but 2 lbs. are not called for. Extracted is no sale at all.
BEESWAX.—Not offering.
A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY.—Our market is fairly active. We quote: 1-lb. sections at 30c.; 1 lb. sections, 22c. 25c.; 2 lb. sections, 20c. 22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.
BEESWAX.—Our supply is gone; we have none to quote.
CROCKER & BLAKE, 57 Chatham Street.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

CORRESPONDENCE

For the American Bee Journal.

At What Age Do Bees Gather Honey?

G. M. DOOLITTLE.

The above heading may be thought by some to be of little interest, but as it has much to do with the surplus honey we get, I thought a few words on the subject would not be amiss. Many seem to suppose that the bee is capable of going to the fields to gather honey as soon as hatched, or in three or four days at least, but some facts prove that they do not do so. Bees may be forced to go to the fields for pollen and honey at the age of 5 or 6 days old, but when the colony is in a normal condition, as it always should be to store honey to the best advantage, the bee is 16 days old before it gathers honey. If we take combs of bees just hatching, and place them in a hive without any bees, as is frequently done to introduce a valuable queen, we will see young bees not over 5 or 6 days old go to the fields, being compelled to do so for water, pollen, etc., because there is none of older age to go; but this does not prove that bees of that age usually do so any more than the experiment of feeding 20 pounds of honey to bees confined to the hive before one pound of wax was produced, proves that it always takes 20 pounds of honey to produce one pound of comb. I have conducted two experiments since I kept bees, to ascertain the age at which bees gather the first honey, and as each proved the same, I believe 16 days to be the time when the bee brings her first load of honey, when the colony is in a normal condition.

The experiment which I tried was this: A black queen was removed from a colony, and an Italian queen introduced in her place about the middle of June. The date was marked on the hive, and as the 21st day thereafter arrived, a careful watch was kept to see when the first Italian bee hatched. When the first Italian had emerged from the cell, a careful watch was again kept of the hive to see when the first Italian took its flight. This happened about 2 p. m., on the eighth day after the first Italian was found hatched, when a few came out for a play spell, but in an hour all had returned, and none but black bees were seen going to and from the hive. As the days passed on the numbers increased at each play spell (about 2 o'clock), but none having the Italian markings were seen, except at these play spells, till the 16th day after the first Italian hatched. At this time a few came in with pollen and honey, commencing to work at about 10 a. m. After this, the number of Italian honey gatherers increased while the number of blacks decreased, until on the 45th day after the last black bee was hatched, when

not a black bee was to be found in or about the hive. If the above is correct, and I believe it is, it will be seen that the eggs, for our honey gatherers, must be laid by the queen 37 days before our main honey harvest, if we would get the best results from our bees; as it takes 21 days from the time the egg is laid to the time the bee emerges from the cell, and this added to the 16 makes the 37 days. The above is applicable to any portion of the country, where a certain flora produces the larger portion of the honey crop. To be sure, the bees from the time they are three days old, help to perform the labors in the hive, such as building comb, feeding the larvae, evaporating nectar, etc., hence are of much value toward securing the crop of honey, if we have plenty of bees besides, over 16 days old, but otherwise all hatching after the middle of the honey harvest are of little use.

Another thing I ascertained by these experiments, which was that the bees which gather the honey are not the ones which deposit it in the cells. I was reading in a bee paper, not long ago, how the loaded bees from the field carried their honey easily to the top of a four story hive. This was used as an argument in favor of placing the empty combs on top of the full ones, instead of raising up the second or third story and placing them between full combs, on the tiering up plan. As far as the loaded bees are concerned, it makes no difference, as will be seen when I state that on the 15th day after the first Italian hatched, when none but black bees were going in and out at the entrance, I found by taking off the cover and examining the sections, that scarce a black bee was in them, but all were Italians, which were at work there, building comb and depositing honey. After this I used an observatory hive containing but one comb. In this I also had black bees as field bees, and young Italians for the inside work. By watching the entrance through the glass, I could see the loaded bees come in, and when one came on the side next to me, I could easily see what it did with the load of honey. The bee would pass along on the comb till it came to a young bee, when it would put out its tongue toward the young bee. If this bee had no load, it would take the honey, but if it had, our field bee must try again till one was found that could take the load, when it was given up to it. The field bee then rested a little while, when it would go for another load. Thus it will be seen that any entrance leading direct to the surplus arrangement, as was formerly made in the Langstroth hive, is of no use, but, on the contrary, a positive damage, as in cool nights it causes the bees to leave the boxes, from allowing too much cold air to enter them. To secure the best results, it is necessary to be fully acquainted with all of these minor points of interest about the bees, so that we may combine them all, and bring them all to bear on that which will produce us the most honey.

Borodino, N. Y.

Country Gentleman.

Using a Standard Frame.

W. Z. HUTCHINSON.

One can now scarcely pick up a bee paper without finding an article with the above heading, and, although all the writers do not agree as to which frame should be taken as the standard, they do agree as to the desirability of all bee-keepers using a frame of the same size. The traffic in bees is becoming quite large, and with so many different-sized frames as there are now in use, the purchaser of bees frequently not only has to perform the disagreeable task of transferring them, in order that they may be in hives like his own, but the discarded hives and frames are seldom of any value, except for kindling wood. Were some frame adopted as the standard, and used by all bee-keepers, the supply business would be greatly simplified and made more profitable, both to the manufacturers and the consumers. Hives, frames, etc., could be manufactured in large quantities, and, at a corresponding lower price, and the delays caused by having to wait while some odd sizes are being manufactured, would be entirely avoided. Experiments, especially those in regard to wintering bees, would be more conclusive and satisfactory, were all frames of the same size, as success or failure could not be attributed to the difference in the size or shape of the frames used.

As the majority of bee-keepers use the Langstroth frame, it is not to be wondered at, that nearly all writers upon this subject, advocate the adoption of the Langstroth frame as the standard. I have always used the American frame, which is about 12 inches square, and I have nearly 100 hives, yet I shall, this season, commence using the Langstroth frame, and another season shall discard the American frame entirely. If I cannot sell the hives and combs to some one who uses that style of hives, I shall transfer the best of the combs, melt the remainder into beeswax, and have the wax manufactured into comb foundation. I will knock the hives to pieces, and use what I can in making Langstroth hives. Heretofore I have reared queens and extracted honey, and for these purposes I regard the American frame as good as any. Now, I shall give the production of comb honey a trial, and, for this business, I am convinced that a shallow frame is preferable. Since the Langstroth is a shallow frame, and is used by a majority of bee-keepers, I shall adopt it.

It has been many times asserted that the Langstroth frame is too shallow for wintering bees successfully in our cold, northern climate. It is asserted that in order to pass the winter safely, bees should cluster beneath their stores—as the heat arising from the cluster keeps the honey warm and in proper condition to be used. It should be remembered that when the warm air arising from a cluster of bees strikes against the covering over the frames, the heat spreads out in a

lateral direction all over the upper portion of the hive, and that bees in search of food, in cold weather, move in a lateral direction between the combs just as readily as they do in an upward direction, and much more readily between combs than they will pass from comb to comb. If any one thinks differently, let him, near the close of the honey season, raise the back end of his Langstroth hive until the hive stands at an angle of 65°, when by the time that cold weather comes, the bees will practically be in a fall hive with their stores above them. Two years ago, just after the close of a very disastrous winter for bees, the editor of the AMERICAN BEE JOURNAL requested his readers to send in reports of how their bees were prepared for winter—whether they were wintered in the cellars, or out-of-doors; the kind of hives used, etc.—and how the bees wintered. From these reports a statistical table was prepared, and one of the facts brought out, was that bees wintered with the least loss in Langstroth hives. Among other remarks the editor made the following:

"Those who have contended that the Langstroth hive is too shallow for wintering, will be surprised to learn that the figures compare very favorably for it. Thus the percentage of losses in all kinds of frame hives is 46; exclusive of the Langstroth hive it is 51, leaving only 43 for the Langstroth, being 8 per cent. in its favor. Again, this report records the results of wintering in 521,330 hives; 211,732 of which were in box hives, leaving 309,598 for all kinds of frame hives. Of the latter, 195,957 are Langstroth—i. e., shallow frames—and 113,561 of all others combined. We really think these figures settle the matter of 'the coming frame.' Had the deep frames been shown to have the advantage, the BEE JOURNAL would have been ready to advocate their universal adoption, for it has no desire to favor any but the most successful methods, hives or implements."

The reason that a shallow frame is better adapted to the production of comb honey, is that the capacity for top-storing is so increased, that the troublesome and vexatious side-storing is avoided, and the honey boxes are brought near the center of the brood nest, which induces the bees to enter more readily. Now, as a shallow frame is best for obtaining comb honey, and equally as good as any for extracted honey, and, as the Langstroth is a shallow frame, and is certainly as good a frame as any upon which to winter bees, and is now largely in the majority, I shall adopt it and do all that I can towards making it the standard frame.

There is some dispute as to the exact dimensions of the Langstroth frame, but the majority of the frames in use are 9 $\frac{1}{8}$ inches deep and 17 $\frac{3}{8}$ inches long. The largest manufacturers of hives, and the greatest number of them, have adopted this size, as have the editors of all of the principal bee periodicals. In Mr. Langstroth's book published 20 years ago, the length of the frames was given as

17 $\frac{3}{8}$ instead of 17 $\frac{5}{8}$, but the introduction, several years ago, of the one-pound section, which is 4 $\frac{1}{4}$ x4 $\frac{1}{4}$ inches square, eight of which just fill a Langstroth frame when made 17 $\frac{3}{8}$ inches in length, outside measurement, is a good reason for making them of that length, and Mr. Langstroth, long ago, publicly indorsed the change to 17 $\frac{3}{8}$.

Rogersville, Mich.

For the American Bee Journal.

Size of Frame—Bees for Business.

JAMES HEDDON.

In reply to Mr. Alves, let me say: 1. The large majority of frame hives used in this country are "made" by the users.

2. Mr. Langstroth has never, to my knowledge, pronounced 17 $\frac{3}{8}$ the standard, and if his fiat will make a standard at any time, I will write to him and possibly induce him to call it 17 $\frac{1}{2}$ x9 $\frac{1}{2}$.

3. I did not object to the mongrel being well adapted to taking the one-pound sections. I only objected to that fact being used as an argument in its favor, asserting that the true standard size 17 $\frac{3}{8}$ would do the same, and that the two-story broad frame system was fast falling into disrepute.

4. I maintain that when a man lays down a system in a book, and gives dimensions of all the parts of his hive connected with that system, together with good and valid reasons for such measurements, spreads that book far and wide, which results in thousands copying after his directions, that such established standard is not to be altered by wrenching from him his assent to a fractional change that can serve no purpose for the better, only annoying bee-keepers with the disastrous results of odd sizes of hives and frames.

5. What Mr. L. says on page 331, has reference solely to principles within the realm of the adaptability of the hive to the instincts of the bees, and not to the convenience of bee masters. I am not willing to cover the fame of this greatest of apicultural inventors with the veil of ignorance that would be thrown over him to suppose that he saw no inconvenience in the size of 40 and 9 different forms and sizes of hives and frames. He wished to impress the minds of the ignorant, that his inventions and patents did cover frames of various sizes.

6. I am in the habit of calling things by their right names, and will call the 17 $\frac{3}{8}$ Langstroth the "obsolete" Langstroth frame when it becomes so. Please do not count the chickens until the eggs hatch.

On one point Mr. Alves and I agree, and that is that we both fail to see that he makes his case any stronger than he did in his first attempt. I thank Mr. A. for his eulogistic words in his closing paragraph, and hope my views on this subject may in the end serve to strengthen his former good opinions.

QUALITIES IN BEES.

In reply to the published questions of Mr. Hutchinson, I little thought of arousing my old antagonist, Mr. Demaree. It seems to me that Mr. D., in his article on page 284, merely repeats the arguments of his former article. This effort strikes the ear like a wail from the tomb of Guiteau: "Not guilty."

Bee-keepers are turning attention to the new system of breeding bees for their qualities, regardless of color or the number of their rings. Mr. Hutchinson sees the point; Mr. Alley says, "that's so;" neighbor Shirley, a breeder of close observation, feels almost out of patience with me that I should have erroneously inferred that he places any special value upon "the gold rings;" he says that he "has been through the mill," and is a firm believer in bees for business; qualities which are not necessarily inseparable from any special number of bands. Such old and excellent breeders as E. A. Thomas, are advertising a strain tested for qualities; and my orders for hybrid queens bid fair to go beyond my ability to supply. And right or wrong, the decision of bee-keepers of to-day is, "Give us bees tested for qualities." It is no wonder that Mr. Demaree considers it high time to "protest against the present tendency" of breeding for qualities, viewing the matter as he does.

I hardly thought after the late editorial scolding, that Mr. D. would again try to blacken the character of those who honestly differ from him, by using such a term as "mercenary tendency." Such statements, as well as the whole article, seem to me entirely uncalled for; and as before stated, I had no idea of again calling out the unchangeable opinions of Mr. Demaree.

"I had supposed the shattered string
Would prove, by now, a silent thing;
But touch it lightly as ye will,
It gives a mournful echo, still."

Now, let us look at the mistakes in Mr. D.'s argument. The mule argument, to begin with. Let me quote from that comic philosopher, Josh Billings. He says: "The mule is half horse and half donkey, and then comes a full stop; nature evidently having discovered her mistake." Again, "I have known the mule to behave first rate all the week for the sake of getting a good fair crack at the driver Saturday night." Again, "The best way to make a mule stay in pasture, is to turn him into an adjoining lot, and let him jump out." This animal ranks as he does because of his unchangeableness. Let us have no mule bees.

I take it that Mr. Demaree, in his experience with hybrids, has never gone beyond the first cross, or if so, merely in a hap-hazard way. The after-crosses judiciously directed by a skilled master, is where we develop as well as retain many superior traits of the character of both races, at the same time doing away with vicious qualities. Three of my present students are bee-keepers of some years experience with Italians. I propose they be consulted upon the points

just referred to, as found in my apiary.

Mr. Demaree believes that every honorable breeder should be able to give a description sufficiently comprehensive to enable any one to identify his bees, and distinguish them from every race or strain of bees. Mr. D. uses the word "strain," can he, roaming the fields, distinguish bees from his apiary, from those of other strains of the same race? I can do this with mine.

Mr. D. thinks I should give a description of my bees. I did so, and it was so plainly given, and so well defined a description that he held it up to ridicule, and sought to make fun of the terms "long-bodied," and "leather-colored;" forms and colors well known to modern bee-keepers. Now he has the audacity to come forward with bees of "plumage," "white silver bands;" "slender in form," and "second-band conspicuously broad," and "generally wearing but little plumage," but that little of a "light silver rather than a golden hue." "Form slender, inclining towards orange banded." Why, if we had not known that Mr. D. was a lawyer, and were we inclined to look upon every new and novel movement as a "mercenary" dodge, I should be induced to believe that Mr. Demaree was about to advertise "Queens for Sale!"

The Legislature of Kentucky is now working on conservative ground. Kentucky always did think that her stock had reached the end of perfection; and consistent with that view, demands "purity of her stock." But will Kentucky and its able lawyer please to remember that their short-horns and blooded horses were not handed down to us from on high, but were produced by the efforts of some one who said: "Let us have better horses and better cows; let us cross this one with that one; let us breed for qualities." Some Legislatures allowed men to bring forth the setter from the spaniel, the pointer from the setter and hound. This was not the Legislature of Kentucky.

Nature has done for the mule what Kentucky would do for all stock, and the mule stands in the stock world just where Kentucky will in the apicultural world, if she passes any such laws regarding bee-breeding, as Mr. D. alludes to in his "aforesaid" article.

Dowagiac, Mich., June 8, 1883.

[As both disputants have now had another "round," let the subject rest. Neither party can be convinced, and no good can come of a mere wordy war; so "give us a rest."—Ed.]

The bee-keepers of Fulton and adjoining counties, are requested to meet at the Commercial House, in Astoria, Fulton, Co., Ill., on Saturday, June 30, at 2 p. m., for the purpose of organizing the Fulton County Bee-Keepers Association. By order, COMMITTEE.

Rural New Yorker.

Queen-Rearing—A Review.

PROF. A. J. COOK.

For some time it has been known that this work was in process of preparation, and from the long and successful experience of the author as a queen breeder—an experience covering more than a score of years—the work has been eagerly looked for by all those engaged in breeding bees. Nor will its study disappoint these ardent expectations. The following is only a brief synopsis of some of the most noteworthy points:

Mr. Alley believes that the same rules of breeding apply in the rearing of bees that should govern in higher animals. Thus he urges stoutly the most careful selection of the queen and drones. He keeps his selected queen in a small hive, so that he can get eggs at once upon adding a frame of bright empty comb. Combs that have contained one or two broods are to be preferred.

The queen-cells should only be formed in very strong colonies. Such are drummed from their hives and kept queenless in an empty hive, in a cellar for ten hours. This fits them better, as Mr. A. thinks, for feeding the queens. To procure queen cells, Mr. Alley cuts the strips of comb which are filled with eggs, so narrow as to contain only one row of entire cells and two rows of half cells each. On one side, the eggs in each alternate cell of the row of uncut cells are destroyed by the use of a common match. By dipping the opposite face of this strip into melted wax and resin mixed, the comb is fastened to a frame of comb and given to the bees, which have been ten hours queenless. No other brood is given them that is uncapped, and so they form beautiful cells, in a regular row, equally spaced, and as the eggs were all laid at a known date, it is known precisely just when the queens will come forth. He never permits more than ten cells to be formed in a single colony. The bees are made queenless in the morning and given the eggs at night. Mr. A., in letting the bees escape from the hive where they have been shut in, to enter the new hive where the queen cells are to be formed, which now rests on the old stand, prevents the drones from leaving, if they are undesirable, and so gets rid of the inferior drones. If the bees cannot gather, they are fed one pint of syrup or honey twice a day. The cells are cut out on the eighth day from hatching, or the eleventh from the laying of the egg. The cells are put into a queen-nursery like that described years ago by Dr. Jewell Davis. A single colony can care for 100 of such cells. A colony is kept purposely for it.

Mr. Alley condemns the lamp nursery, though he confesses he never used it. He says it is unnatural. The same argument would condemn his whole method. He has improved upon nature. Some of our best queen breeders, like Viallon, Hutchinson and Hayhurst, use the lamp nursery and think it excellent. He says if

we feed young queens in a queen nursery, they will remain there safely several weeks. But what of Berlepsch's theory that a queen unmated for three weeks is ruined?

Mr. Alley introduces the queens as virgins. But the old colony or nucleus must have been queenless three days. He uses tobacco to smoke them, and thinks this is a *sine qua non*. He also advises dropping a virgin queen into honey and then into the hive. He sometimes introduces these virgins by use of a cage, stopping the entrance—a half inch hole an inch long—with the "Good candy." The bees eat the candy, liberate the queen and accept her.

Mr. Alley never uses a colony twice in succession to form cells. After they are used once, he gives them the uncapped brood and queen of another colony which is to be used, and considers them ready again in four weeks. Thus queens are always reared from eggs; few are reared in each colony; these have all the attention, and "are almost sure to be superior queens." The nucleus or colony receiving a virgin queen should not be near the colony which is forming cells at the time, or the young queen, as she returns from mating, will enter the hive and destroy all the cells. If a queen is "balled" as she returns from mating, it is a very sure sign of the presence of fertile workers.

Mr. Alley's instruction as to introducing virgin queens is very valuable, if the method will work in other hands. In this case the colony, or nucleus, must have been queenless three days. Not so with a cell. This he says (our experience hardly sustains him) may be introduced safely immediately upon the removal of the queen.

The cell need not be fastened in a comb, but held by slight pressure between two adjacent combs. Late queens will often fail to fly unless fed a little each day. Mr. Alley is surely right, in saying that queens mate only once. He thinks a queen is almost sure to be purely mated if there are no impure bees within half a mile. I wish we were sure of this.

Caged queens, Mr. Alley says, will not be so fed by the bees, and these must be fed in the cage. Judge Andrews, of Texas, says they will always be fed. Bees in a nucleus, unless fed, will frequently swarm out. Mr. Alley secures his selected drones in this wise: He places empty drone combs in the midst of the brood nest of his best colony. As soon as eggs are laid in the cells, he gives these combs to queenless colonies. Good queens lay regularly in cells, and cut the caps from the queen cells as they come forth smoothly, and do not leave a ragged edge. He makes the strange assertion, that Italians are not a distinct race, and, further, states that they are poor nurses. Mr. Alley quotes wrongly, I think, from our books. I think all advise getting eggs of a known date. It is stated that worker bees never destroy a queen cell. In handling queen cells, they must never be over-heated. They will stand cold better, but ought never to be chilled.

Mr. Alley thinks it is dangerous to ship a queen right from active laying—she may be ruined. It is much safer to cage her a few days first. Cheap queens are vehemently condemned.

Mr. Alley adds to the usual rules in respect to robbing, that we ought not to feed honey but syrup. The honey odor incites to robbing. It is stated that by giving a colony brood, and a queen cell, fertile workers may be disposed of. Mr. Alley advises, none too strongly, to displace impotent queens. He remarks as wisely that most queens become unprofitable after two years. I am also glad to see that the value of spring feeding, which I have so often demonstrated in our College apiary, is fully recognized. It is no exaggeration, I think, when he states that at least ten days are thus saved. The greatest error, I think, is made in reference to wintering. He favors out-door wintering; says we must have a double-walled hive, 25 pounds of honey and a February light. But, how often we get no February light. With a proper cellar we may keep the bees in the hives safely from Nov. 1 till April 1.

Mr. Alley thinks that although the laws of parthenogenesis are certainly true in respect to the production of drones; yet the fact that queens are pure, he thinks not a guaranty that their drone progeny will be. His only reason given is that it is not true of birds. From very close and long observation, I believe that it is true of bees.

Lausing, Mich.

Honey from Corn—A Reply.

W. H. STEWART.

On page 85, Feb. 7, I find a criticism by the Rev. M. Mahin, D. D., on my article as published in the BEE JOURNAL of Jan. 24, 1883.

The science of bee-culture (if it may properly be called a science) is yet in its infancy, and its growth must be step by step, as new discoveries are made. No new discoveries, mean no development of truth. A statement supported by facts is scientific. A denial without proof is just the opposite. He who attempts to set up a negative case by mere denial, unsupported by proof, lands himself in inconsistency.

I do not hold that my work is exempt from trial at the bar of reason, observation and experience. Nay, I court criticism. It leads to investigation, and investigation evolves truth. The art of bee-culture is not confined within the walls of limitation. It has had a beginning, but it can have no ending.

The sons of men that come and go,
Each have a special work to do;
These works just suited to their time
And place, are steps by which we climb.

One forward step; one higher stand,
How wide, how vast the fields expand;
Where sons of men may ply anew,
Their hand and brain some work to do.

Criticism should be conducted seriously, having but one object in view, viz.: truth, but Mr. Mahin says that

my work is too absurd to be treated seriously. Let us see. Do bees wound flowers? In A B C of Bee-Culture, page 168, Mr. Root tells us that he discovered how the bees got so covered with pollen while working on the wild tullen-me-not, and on page 169 he says: "A year or two after this I took a friend of mine to the spot to show him my wonderful discovery, but lo! and behold! the sharp witted Italians had taken the short cut to the honey by biting through the spur and inserting their tongues without the laborious operation of crowding down into the flowers."

Mr. Mahin chides me for not giving proof that bees wound blossoms. Here is proof that bees are able, and that they did in this case, bite holes through the flower and got at the honey mechanically from the outside. In my article I stated that "if bees would have honey they must find where the plant had by accident or otherwise been wounded, or it must hunt out some tender point and inflict the wound as best it could." I do not hold that bees must, like men, chop holes in the trunks of maple trees to get the sap, but I do know that after men have thus set the sap leaking, the bees gather it. But in regard to bees hunting out some tender points to inflict the wound itself. The tenderest portion of the blossom is as much a portion of the plant as is the trunk.

Now, in regard to the corn honey, Mr. Mahin says that "corn honey is a myth." When I quoted Mr. Morris, in regard to corn honey, I did not give his statement verbatim, as it was lengthy. I will now give the statement of Mr. Morris from *Gleanings*, of December, 1882: "Sometime in August * * * when white clover was about played out, the bees took a spurt, and for several days we failed to find what they were working on; heartsease and goldenrod were not in bloom. My wife called my attention to it first. She had followed the line of bees, and found the corn field swarming with bees. At first you would suppose a swarm was going over, and wonder where they were. Stand still a moment, however, and you will see a bee come from under the base of a corn leaf, then one from between the stem of an ear and the stalk, then some from way down by the roots, and by that time you will begin to see where they are getting the honey, not from the silk, not from the blossom, but from the stalk, at the base of every leaf at each joint, and on every stalk, and on every hill. We obtained 500 pounds of extracted, same of box, of this same corn honey, and you will see by the sample it is nice. Bees worked on the corn about two weeks. Field corn begins to yield honey about as the kernel begins to form, and continues until the kernel is well formed. At least it did here this year.... I think it always yields honey, some every year, but you cannot always tell what is going to yield honey." H. M. MORRIS.

At the close of the above letter from Mr. Morris, Mr. A. I. Root remarks: "Many thanks friend M. for

your valuable contribution to our stock of facts, and also for the sample of honey. The corn honey will rank with the best we have, both in color and flavor.... I would strongly indorse the point you make, friend M., about the honey coming from unexpected sources. We little know now where the honey we may get next season will come from, while the honey comes from so many hitherto unknown sources, and there is such a broad field of knowledge yet unexplored."

Mr. Morris says in the BEE JOURNAL, page 145: "Mr. Stewart quotes me from *Gleanings* a little wrong. I said: I think bees gather some honey each year from corn. His statement is that my bees gather large quantities of corn honey each year. I know that they did this year. Corn honey has such a peculiar quality that if one ever gets a yield, he will be apt to know it if he ever gets another, and I am quite sure I have had corn honey before."

Mr. Mahin says that "if Mr. Morris ever saw bees sucking at the joints of corn stalks.... the corn was infested with chinch bugs, or some species of plant lice." Mr. Morris and his wife would most likely have noticed chinch bugs if they had been on the corn in such numbers as to produce the effect that he reports.

Mr. Mahin says, "that he has watched bees by the half hour gathering honey from clover, etc." If he has, and has read a corresponding amount of modern literature on bee-culture, he must know that honey gathered after plant lice is of an inferior quality. Mr. Morris and Mr. Root both testify that the above mentioned corn honey was a fine article. And yet, again, Mr. Mahin says, "that if bees can work on corn, as we believe they can, they would break the skin of grapes, and we would have to acknowledge that we were liable to the grape growers for the damage to their crops, which we have claimed was done by birds and wasps, etc."

Mr. Mahin has based his hyper-criticism on a misconception. Did I not show that our choice fruits, etc., all came by cutting, pruning and up-rooting of the plants, and also that white clover thrived best where it was most severely pruned? He should know that plants and fruit are subject to a law of growth, and they may be wounded to a certain extent without producing any perceptible injury.

Growth is continually laying off old conditions and building on new, changing acid to nectar, healing wounds, supplying waste, increasing dimensions, changing form, etc., and yet the health of the plant remains.

If Mr. Mahin will experiment one-half an hour in June and July, he will find that fruit may be pricked with a fine needle through the skin, (if done carefully), and the fruit remain healthy.

Orion, Wis., May 4, 1883.

The Central Kansas Bee-Keepers' Association will meet at Manhattan, Kansas, on June 30, 1883.

THOS. BASSLER, Sec.

SELECTIONS FROM OUR LETTER BOX

White Clover Bloom.

The boom is here on white clover. The ground is literally covered with bloom. The bees are busy from morning till night. The battle opened this day week, and the hives are now full of honey, and the bees are working in the boxes. It is the finest flow I ever saw.

I. H. SHIMER.

Hillsboro, Ill., June 7, 1883.

Good Prospect for Honey in New York.

My 30 colonies wintered without loss, but I lost 2 by spring dwindling. They are now in good condition for the honey harvest, for which the prospect is good.

CHARLIE W. BRADISH.

Glendale, N. Y., June 10, 1883.

Discussion on the Best Frame.

I have had some letters concerning my article on page 263; they speak of it as a challenge to discuss the frame subject. I ask all to read the article once more. Generally discussion soon merges into contention; and then long articles are written on both sides, to show that what one asserted is true or false, when, whether true or false, is of no consequence; for instance, of what use is it to know if they have got the Langstroth frame $\frac{1}{2}$ inch too large, to a sensible man that uses a sensible frame. J. W. Porter's style, on page 288, is what we want.

E. B. SOUTHWICK.

Mendon, Mich., June 8, 1883.

Not at all Discouraged.

I put 112 colonies of bees in the cellar last fall, and took out 108, all in good condition. The spring has been cold and windy. The bees consumed more honey this spring, than during all the winter. I never lose any bees unless I was to blame for not having them in proper condition for winter. I can manage 300 colonies alone, with some cheap help to make hives and boxes, and to assist in swarming time.

CHAS. FOLLETT.

Osage, Iowa, June 8, 1883.

Mock Orange for Honey.

Bees, in this vicinity, are swarming, very lively. I have had 9 swarms; one colony having given 3 swarms, viz.: May 26, June 1, and June 4. Another one, an Italian, has swarmed twice. My bees have stored no honey in the surplus boxes yet, but I expect to receive some soon, as the Alsike, white clover and locust are in bloom. The ants are very troublesome, making their nests in the upper story, around the surplus boxes, and running into the lower story when I open the hives, irritating the bees so that it is impossible to work with them. Basswood, which commences to bloom about July 1, is very full of bloom, this year. I enclose a flower and leaf for name. It is an ornamental shrub commencing to bloom about

May 25, and lasting from 4 to 5 weeks, during which time it is entirely covered with bees. The leaves are almost hid by flowers. F. A. BOILL.

Summum, Ill., June 4, 1883.

[It is mock orange (*Philadelphus coronaria*); an exotic shrub, very commonly cultivated.—T. J. BURRILL.]

Swarming and Storing Honey in Ark.

I started the spring with 30 colonies; and have already taken over 2,000 pounds of extracted and 60 pounds of comb honey. Had it not been for the recent cold weather and the last few days of rain, I should have done much better. I have an increase of 15 good strong swarms. I would not be without the BEE JOURNAL for any price. I shall work a large number of colonies, another season.

R. J. ADAMS.

Lakeport, Ark., June 5, 1883.

Long, Cold Spring Weather.

We have had a long, cold winter; and even since the spring quarter has appeared, we have had only sometimes a day which we rejoice to see, as a summer day, but the day following, and for several days, the old cold gloom again. One day in May, it commenced to rain, then turned to snow, and snowed the whole afternoon; however, at present, and for some days past, it appears like settled summer weather, and plum trees are in full bloom. There is an abundance of dandelion bloom, apple trees also are coming in nicely, and I hope we shall have a good season yet.

EDWARD MOORE.

Barrie, Ont., June 5, 1883.

National Convention.

Providence permitting, I shall go to the National Convention at Toronto, if the time is made to suit. For my own part, and I believe the majority of Southern bee-keepers, would prefer the last of September, as the most suitable time for holding the meeting, or not later than the 10th of October. The reason I prefer September is, there are more opportunities then offered for the purchase of "excursion tickets" to the North. I hope the committee of arrangements will select the time at as early a day as possible, so as to give bee-keepers ample time to effect all necessary arrangements to go.

J. P. H. BROWN.

Augusta, Ga., June 7, 1883.

Too Much Rain.

We have had rain, rain, rain, for the past two weeks, till everything is flooded with water. It became warm about May 25, but since then it has been so wet that the bees could do little or nothing. I am feeding my bees to keep them from starving. White clover promises well, and with good weather I hope the bees will soon get a living. My best colony gave a swarm on the 9th, owing to extra care, as I wished to get queen-cells produced by natural swarming as early as possible for queen-rearing.

G. M. DOOLITTLE.

Borodino, N. Y., June 12, 1883.

Good Outlook for Honey.

I put into winter quarters 45 good strong colonies, and 44 came out. My bees are in fine condition, and are booming, giving from one to five swarms every day. My section boxes are almost ready to take off. White clover is abundant, and the outlook is good.

WM. TAYLOR.

Sinclair, Ill., June 11, 1883.

Wonderful Honey Plant.

The winter before last I procured a small package of sweet clover (*melilot*) seed, and sowed about 6 square rods in March, 1882, for a test. It grew last year, and sent its roots well in the ground. The past spring it shot up from the roots quite early, and, although from the first week in April to the present time, a good rain has not fallen on it, it put on a wonderful growth, and much of it is 6 feet high. It began to bloom about the middle of May, and is now a perfect mass of flowers, swarming with bees. I do not know how long it will last, but it certainly is one of the finest honey plants I ever saw. I think an acre of it would supply a large apiary. It is certainly worth trying in Texas, as it seems to resist the effects of dry weather so well. The spring has not been a favorable one for bees; but little swarming; doing well now, however.

W. P. HANCOCK.

Salado, Texas, June 7, 1883.

Perpetual Bloom.

On April 1, 1883, I sold off what bees I had in Southern Nebraska, and I made up my mind to find a milder climate for myself, and also a place that my bees would not have to remain housed for from 5 to 6 months in the year. Here, near Trankeyone, we are locating an apiary of 200 colonies, some of which have, at this writing, 70 pounds of as fine honey as I have ever saw. The honey flow has every appearance of being good for 6 to 7 weeks yet. This is a land of almost perpetual bloom, as I am told by the oldest inhabitants, the climate being so mild that it scarcely ever freezes, and at the same time never becomes extremely hot; it is rarely above 70 Fahr. All kinds of fruit grow to perfection here. Apple, pear, peach, apricot, plum, cherry, grapes, oranges, lemons, prunes, figs and almonds, and small fruits, such as currants, raspberries, blackberries, etc. The wheat and barley crop promises a big yield. Trankeyone is a signal station on the coast range, in Southern California.

JOSEPH SAYLER.

Santa Barbara Co., Cal., June 1, 1883.

Bees Doing Lively Work.

We have had a very cold, wet spring here; but, in spite of the cold and wet, my bees are doing finely. I had the largest natural swarm, to-day, that I ever saw. I could hardly get them into a one-story simplicity hive. They have been storing honey from the willow. Basswood will not bloom till late; the bees of this locality are nearly all black.

CHAS. HARROLD.

Onawa, Iowa, June 3, 1883.

Sweet Clover.

I enclose a part of a plant; will you give the name, and also please let me know if it is a honey plant? Bees seem to like it very well. It comes early in the spring, and grows about $3\frac{1}{2}$ or 4 feet high, when the bloom comes. A great many limbs or sprouts come from the same root. It blooms the second year from seed.

L. R. WILLIAMS.

Paris, Texas, May 28, 1883.

[It is *melilotus alba*, or sweet clover, and is an excellent honey plant.—ED.]

Bees in Louisiana.

Bees, in this locality, are doing poorly, owing to the late spring and cold rains. Most of us have finished dividing, and are now waiting for a little sunshine, so that we may commence extracting. In this parish are about 2,500 colonies of bees, which are contained in about 15 different apiaries; all of which are run exclusively for extracted honey. Of course, scattered all through the country, are a few hives of bees, kept by the farmers' wives for their own use; these I did not count. I should like to know whether it is infringing on a patent to repair a patented article when it is broken? Please tell us something about Florida, Colorado and New Mexico through the columns of your valuable paper, for we Louisianians are tired of being flooded every spring, and are thinking seriously of emigrating *en masse*.

T. M. HINES.

Point Coupee, La., June 4, 1884.

[Of course you can repair, or do anything you like with a patented article, after you have purchased it, except to make others like it. Our correspondent will find considerable in the BEE JOURNAL about the localities named, especially in relation to their adaptability for progressive bee-keeping.—ED.]

Magnificent Flow of Honey.

My bees have gone crazy on the honey question. I never saw such a flow of honey before.

JOSEPH E. SHAVER.

North River, Va., June 8, 1883.

Basswood Promises Well.

Please find enclosed a leaf that I would like to know the name of, and its importance as a honey producer. I only know of a little of it along the roadside, and it is alive with bees from morning till night; blooming at the time it does, between fruit tree bloom and basswood, it might be valuable for bees if it has no objectionable qualities to over-balance the good. My bees are strong; have been starting queen-cells, but a scarcity of honey and unfavorable weather caused them to destroy the cells. There is very little white clover here, and I expect I will have to feed some between now and basswood bloom, which promises to be good. Almost every one seems to be giving their preferences in regard to a standard

frame, and all seem perfectly willing to adopt a standard, provided they adopt their preference. I think a compromise between a deep and shallow frame would be the best to unite on. I think it would be easier to unite, if the advocates of both deep and shallow frames would give a little, and I would endorse the frame recommended by Mr. P. P. N. E. Pellissier, on page 240, 10 inches deep by 15 inches long, inside measure. I am not using that size, but would be willing to adopt it. L. G. PURVIS.

Oregon, Mo., May 28, 1883.

[The leaf is not recognized. It is hard to determine plants from the leaf alone. Send part of the stem and especially the flower.—ED.]

Excellent Prospects for Honey.

I put into winter quarters 46 colonies, and 43 came out in fair condition; but I have lost, up to date, 5 more, leaving 38 now, all but 5 are ready to go into sections. I had hard work to keep them up, but I am satisfied to have them in this condition, after such a severe spring. I expect a good honey yield; white clover has commenced to yield honey, and there is as good a stand of it as I have ever seen. Our bees did not get enough, up to date, to keep breeding; I had to feed them largely, but hope now it is all right. I will report my experiments on wintering before fall.

A. WICHERTS.

Mattison, Ill., June 8, 1883.

Mountain Maple for Honey.

Will you please name, in the BEE JOURNAL, the enclosed plant. It grows on a tree something like the maple, and the roaring of the bees upon it to-day, attracted my attention. Fruit bloom is just done, and and if this is a good honey plant, as the working of the bees seems to indicate, it may be made to fill an important gap in the honey flow. I could not find another tree like the one from which I picked these leaves and flower.

JAMES MCNEILL.

Hudson, N. Y., May 29, 1883.

[This is the mountain maple (*Acer spicatum*), a small native tree, widely dispersed through the heavily-wooded portions of the United States and Canada.—T. J. BURRILL.]

Backwardness of the Season.

The cold and backward spring has been pretty hard on the weak colonies of bees in this section, but strong colonies are booming. Geo. C. Green, of Factoryville, $1\frac{1}{2}$ miles from here, had a large swarm about two weeks ago. He winters his bees in chaff hives; has some 30 colonies, and lost none. I have 8 colonies in plain Simplicity hives; 6 of them I packed with chaff cushions, and the other 2 I left to themselves, as they were weak ones, and I thought it was not worth while to bother with them. Did they live through the long cold winter? Yes sir; and came out just as well as the rest, having quite as large a pro-

portion of their number ready for business as the others had. Why "this was thus," I cannot say unless, as the old gentleman remarked at the convention the other day, "It was just their contrary way." I wish you, Mr. Editor, would stir up those who advertise queens to sell, etc., to be a little more prompt in filling orders, or say plainly that they cannot immediately do as they advertise. Sometimes those who call themselves "square men," get a bad reputation by not being prompt. I ordered some queens some two weeks ago from a breeder who wrote me that he could send them on five days notice, but not a queen is here yet, although a letter will reach him in less than two days. I ordered more, from another breeder in the South, who claims, in his circular, to be able to fill orders in April, but not a queen do I get. In his acknowledgement of my order, he said it was cold there, and he was afraid they would die in the mails. That was three weeks ago. The mercury now stands at 85- to 88° in the shade, and he is only twodays and half away. Are they all alive? I think not; but, from the little dealings I have had with some of them, I fear a majority belong to the three-handed army; that is, they have a right hand, a left hand, and a little behind-hand.

"CONNOISSEUR."

La Plume, Pa., June 5, 1883.

[The weather, this spring, has been such, not only in the North, but also in the South, that queens could not be reared and fertilized, much less shipped to fill orders. Our correspondent should remember that the circulars were gotten out in the winter, and no one could then foresee the terribly backwardness of the spring. Beeders calculated on the usual weather, but have been treated to some very unusual, this spring. All must exercise patience, eat a little more honey, and keep sweet-tempered.—ED.]

Toads—A Dangerous Bee Trap.

A few evenings since I went out to my apiary, and in front of the entrance to one hive I discovered a large toad. I watched him a few moments, and saw him catch bees as they ventured out on the alighting board. The toad would twist his mouth and turn from one side to another after swallowing a bee. I caught the toad and made an investigation. First cutting off his head, I examined the inside of the mouth, where was found several stingers in the jaw and roots of the tongue, where the bees had stung him when he closed his mouth upon them. I then opened the body and pressed upon the stomach, when nine nice Italian bees came out, lifeless. Others remained in the stomach, enough, I think, to have made the number 18 or 20. In answer to the question, "Will toads catch bees?" I can certainly answer, *they will*.

W. A. SHEWMAN.

Randolph, N. Y., June 9, 1883.

Bringing in the Golden Nectar.

I think I can say that I am "out of the woods" for this season, and will report, SUCCESS. I put into winter quarters 68 colonies, and never had them do better, until I gave them a flight late in February. I put them on their summer stands, in the first days of April, when I had lost 2 colonies. There was ten times as many dead bees on the cellar floor, on the first day of April, as there was on the first of March. I should like to have a reason for this, as they were kept as nearly as possible in the same condition through March as though the three preceding months. I have lost 3 colonies by dwindling, since the first of April, leaving 63 colonies in good condition; some of them very strong, hanging out, and giving strong indications of swarming. Mr. Layer, of Gilman, reports a fine swarm on the 23d of May. White clover is beginning to bloom, and for the last two days, they are working lively, bringing in the golden nectar, and their busy hum, to me, is sweet music. The more I am with the pets, the better I understand their language, for a language they have, most certainly, and it is well to understand and heed their words, or they may use something sharper.

REUBEN HAVENS.

Onarga, Ill., June 4, 1883.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Will my friends please send their questions to the Editor of the JOURNAL, and not to me; they will be answered just as promptly. I now have a short-hand reporter who can take down my answers as fast as I can think them, which enables me to "talk back" with great satisfaction, so send along your questions, but to Mr. Newman and not to me, please.

Queen Rearing.

Will Mr. Heddon give us his opinion of Mr. Alley's book, "New Method of Queen Rearing?" I have seen the same method of obtaining queen-cells practiced three years ago, in a large apiary, in a neighboring county.

C. W. GREEN.

New Orleans, La., June 7, 1883.

ANSWER.—I regret very much that I am unable to give my opinion upon Mr. Alley's "New Method of Queen-Rearing." Mr. Alley kindly sent me a copy, asking for my opinion, but I have been too busy to read it. I must fill my engagements and answer business letters, and this takes all of my time, and overtaxes me at that. I

did read Mr. House's chapter on "Comb honey production," and also Mr. Locke's on the "Races of bees," therein contained. I disagree entirely with the tenets of both these chapters.

Drum Box and After-Swarms.

I would like to have Mr. Heddon answer these questions:

1. How does he prevent after-swarming?

2. Explain his drum box; is it in any wise different from a common box made to fit the top of the box hive he is transferring?

3. I have had 8 swarms from 3 colonies already. Bees have been storing surplus since April 1.

GEO. E. LYTLE.

Flat Bayou, Ark., May 28, 1883.

ANSWERS.—1. We very rarely have any attempt at after-swarming. If such are cast, we hive the after-swarm in a hive of comb foundation, and put it by the side of the old box. When the 21 days have passed, we then drive the bees in the old box into the hive with the after-swarm, and, at the same time, all three can be put together if you were driving on the non-increasing plan.

2. My drum box is simply a box of about the size of the hive to be drummed, but I think it would be an improvement, one I thought of 7 or 8 years ago, but have never made, to have a drum box contain numerous thin light division-boards, to enable the bees to readily ascend from all parts of the old hive.

Antiquated Management.

Will Mr. Heddon kindly answer the following questions through the AMERICAN BEE JOURNAL, for a friend:

1. If a man is doing all his own work, can he manage more bees for comb honey production, or for extracted honey?

2. Which way can he produce the greatest number of pounds, by using sections or extracting?

3. Can comb honey be shipped safely to market in the Langstroth frame, and would it find ready sale?

4. Would there be any market for comb honey in 10 or 20 pound boxes, such as were used 20 or 25 years ago?

5. I write this for the benefit of a friend. The questions being fully settled in my mind, and he being willing to abide by your answer.

G. C. VAUGHT.

Greenville, Miss.

ANSWERS.—1. We must understand that less colonies are required to gather the honey of a given area, when they are working for extracted honey than when working for comb honey. With proper fixtures in both

cases, there is not much difference, if any, in the amount of labor required.

2. If he is getting extracted honey for saucer, and takes out a ripe article, he will get but little more extracted than comb honey, provided he thoroughly understands the law governing the production of comb honey.

3. To this question I answer No. The smaller the frame or sections honey is put up in, the safer it will be during transit. The full-sized Langstroth frame would be unsafe, besides there are hundreds of other objections against using it. It would not find ready sale in packages of that size.

4. Occasionally some odd genius might demand it in that shape, but as a rule there would be no market for it. The honey would have to sell at several cents per pound lower.

5. I hardly thought any reader of the AMERICAN BEE JOURNAL would be apt to ask such questions. The small sections are not only more salable at the present time, but the most transportable packages, and the most economical, labor and prices both considered.

Fertile Workers, etc.

The season is from two to three weeks late here, but we escaped the snow storm of May 21, that was so destructive through Ohio and further South. We also have had but little frost, and fruit prospects are good for apples and cherries, and all kinds of small fruit; clover has wintered well, and has an enormous growth for this date; wheat promises to be above the average through this section.

1. How soon, after a colony becomes queenless, will fertile workers make their appearance?

2. Cannot queens be induced to lay to their utmost capacity in a single season, and thus become worthless after, by removing and replacing combs; the queen being in a strong colony?

3. What objection would there be to crossing the Holy Land bees with the pure Italians? Are they as irritable as other hybrid bees?

S. J. YOUNGMAN.

Cato, Mich., June 7, 1883.

ANSWERS.—1. There is no definite time. I have known them to appear in a few days after becoming queenless; at other times, several weeks after.

2. I have found that queens can be stimulated to lay such an amount of eggs in one or two seasons that they seem to have exhausted their fertility.

3. The main objection to crossing the Holy Land bees with Italians, is that they have not the valuable qualities possessed by the Italians, which every comb honey producer so

much needs, but the brown Germans have, and this is why the very best honey-gatherers can be procured by judicious crossings of leather-colored Italian and brown German bees. There is no need of losing any amiability in such crossing as the one last referred to. It is the simplest and easiest thing in the world to increase it.

The Holy Land bees have two traits of character, which must forever keep them from the apiaries of wise honey-producers. First, they are terribly irascible; secondly, they do not ripen their honey properly before sealing it, which causes it to press against the capping and ooze out. I have never had them in my apiary, I am happy to affirm; but good reliable parties, who have tested them thoroughly, furnish me proof of the above statements.

The brown German bee excels any bee in the world, in the much desirable point of building white comb, and doing it readily and rapidly; also in ascending to the upper story early in the season, and in not crowding the brood-chamber with honey. These valuable traits no wise honey producer will ignore. Another valuable point about them is, they are not nearly as much inclined to swarm as the yellow races of bees.

Transferring.

I have been transferring bees from American hives into others, but have not yet finished. Would you advise me to finish now? Please answer through the BEE JOURNAL and oblige. SILAS REMINGTON.

Lowell, Mich.

ANSWER.—We practice transferring either on the old system or the new, all through the season, when convenient, and see no reason why you should not finish the job at once.

Separators with Broad Frames.

Several correspondents have asked me if I considered it advisable to use separators with broad frames. I will reply that I do. When I run 34 broad frame supers, I tried omitting the separators. I find that while the "case" seems not to need separators to get reasonably straight combs, the broad frames are almost a total failure without them.

Bees are just beginning to swarm and store in cases here. The prospects are good. "After clouds, sunshine." We are now transferring several colonies on the new plan, which the students think "the boss."

Special Notices.

Examine the Date, following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

☞ Do not send coins in a letter. It is dangerous and increases the postage unnecessarily. Always send postage stamps, for fractions of a dollar, and, if you can get them—one-cent stamps; if not, any denomination of postage stamps will do.

☞ Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Special Notice.—We will, hereafter, supply the Weekly BEE JOURNAL for one year, and the seventh edition of Prof. Cook's Manual of the Apiary, bound in fine cloth, for \$2.75, or the Monthly Bee Journal, and the Manual in cloth for \$1.75. As this offer will soon be withdrawn, those who desire it should send for the book at once.

Sample Copies of the AMERICAN BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

To Europe and Return for 30 Cents.

If you can't afford to pay \$22 for one of W. H. Brearley's round trip excursion tickets "From Detroit to the Sea," with which you could leave Detroit June 27th, July 11th or July 25th, for a 2,300 mile pleasure tour to the White Mts. and Sea Shore, the "next" best thing would be to send ten 3 cent stamps to W. H. Brearley, of the Detroit (Mich.) "Evening News," for a copy of his new 68-page illustrated excursion guide book. It also contains particulars of 3 cheap excursions "From Detroit across the Sea" to Liverpool. The book is graphic in its descriptions, and affords for thirty cents an excellent substitute for an excursion to Europe, with the advantage that calm weather and exemption from sea sickness may be relied upon. One of these guide books has been received at the office of this paper, where it may be examined by any one interested.

Bingham Smoker Corner.

Large Smokers need wide shields. Bingham's have them, and springs that do not rust and break, and bellows that sparks and smoke do not enter. The Conqueror has all improvements made to date, and a 3x7 inch stove, and 5x7 inch bellows. Sent post-paid for \$1.75. Address,

BINGHAM & HETHERINGTON,
Abronla, Mich.

All Excelling. — Messrs. Bingham & Hetherington, Dear Sirs:—I am now selling your Smokers almost exclusively. You are excelling yourselves in smokers all the time.

Respectfully, J. G. TAYLOR.
Austin, Texas, May 10, 1883.

Cyprians Conquered.

All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am "boss." Bingham's "Conqueror Smoker" did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham.

G. M. DOOLITTLE.
Bordino, N. Y., Aug. 15, 1882.

During the following three months, Bingham Smokers will be sent post-paid, per mail, on receipt of the following prices:

The "Doctor" (wide shield)—3½ in. fire tube, \$2.00
The Conqueror (wide shield)—3 in. fire tube, 1.75
Large..... (wide shield)—2½ in. fire tube, 1.50
Extra..... (wide shield)—2 in. fire tube, 1.25
Plain..... (nar. shield)—2 in. fire tube, 1.00
Little Wonder (nar. shield)—1½ in. fire tube, .75
Bingham & Hetherington Unwapping Knife, 1.15

With thanks for letters of encouragement, and the absence of complaining ones, we tender to our thirty-five thousand patrons our best wishes.
Very Respectfully Yours,

BINGHAM & HETHERINGTON,
Abronla, Mich., June 1, 1883.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Do not let your numbers of the BEE JOURNAL for 1882 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

May we ask you, dear reader, to speak a good word for the BEE JOURNAL to neighbors who keep bees, and send on at least one new subscription with your own? Our premium, "Bees and Honey," in cloth, for one new subscriber to the Weekly, or two for the Monthly, besides your own subscription to either edition, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

W. Z. HUTCHINSON,
Rogersville, Genesee County, Mich.,

Makes a specialty of rearing dark, leather-colored ITALIAN QUEENS. Untested Queens, \$3.00 each, or six for \$5.00; twelve for \$10.00. Tested Queens, \$2.00 each. Safe arrival guaranteed. Make money orders payable at Flint, Mich. 25DIT

BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS C. NEWMAN.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most honey in its best and most attractive condition.

Appreciative Notices.

A neat and abundantly illustrated hand-book of apiculture.—American Agriculturist, N. Y.

Its chapter on marketing honey is worth many times its cost.—Citizen, Pulaski, Tenn.

Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of every beginner with bees.—News, Keithsburg, Ill.

Valuable for all who are interested in the care and management of bees.—Dem., Allegan, Mich.

Engravings are fine. Gotten up in the best style, and is cheap at the price.—Farmer, Cleveland, O.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—Farmer, Lancaster, Pa.

PRICE—Bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

THOMAS C. NEWMAN.

925 W. Madison St., Chicago, Ill.

BE SURE

To send a postal card for our illustrated Catalogue of Apian Supplies here or purchasing elsewhere. It contains illustrations and descriptions of everything new and valuable needed in an apiary at the lowest prices. Italian Queens and Bees. Parties intending to purchase bees in lots of 100 colonies or more are invited to correspond.

J. C. SAYLES,

Hartford, Wis.

1883.

YOU GET VALUE RECEIVED!

QUEENS, BEES AND SUPPLIES

If you want EARLY QUEENS from the best improved genuine stock for business; or if you want Imported Italian Queens or Bees, in full colonies or nuclei, with tested or untested queens; if you want Danish or Vandervort comb foundation, made from pure beeswax; or if you want hives or apian supplies of any kind, send for my new catalogue. It tells you about introducing queens, new "Races of Bees," etc. Cash paid for clean beeswax. Address,

J. P. H. BROWN,
Augusta, Georgia.

1883. JOSEPH D. ENAS, 1883.
(Sunny Side Apiary.)

Pure Italian Queens, Bees, Colonies, Nuclei, EXTRACTORS, COMB FOUNDATION, &c

Address, Sunny Side Apiary, NAPA, CAL.

ITALIAN AND HOLY LAND QUEENS!

The Handsomest Queens for BUSINESS the World Produces.

BUSINESS, BEAUTY and Wintering Qualities Combined.

We CHALLENGE the WORLD to EQUAL them.

Every Queen WARRANTED perfect, and reared under the swarming impulse. Tested Queens of either race, each \$2.00; with "Handy Book," \$2.50. Queens warranted as good as tested and "Handy Book," \$2.25. Special rates by the quantity. Send for our 32-page Circular. 22Atf

HENRY ALLEY, WENHAM, MASS.

4 H. P. Horizontal Single Return-Flue Portable Engine and Boiler

Mounted on skids, engine on top of boiler; cyl. 4½x8; complete with Pump, Heater, Safety Valve, Steam-gauge, Brass Oil Cups and Lubricator 30 inch Band Wheel. Can change engine to run either way; also, stroke of Pump, to pump fast or slow; also, speed of engine. This rig is in good order—sound and strong—would make a good rig for light work. Will deliver on board cars for \$125.00. At this price it must be taken soon. On receipt of \$25 I will send it C. O. D. if desired. Reason for selling, I have bargained for a larger one.

D. G. WEBSTER, Blaine, Boone Co., Ill.

BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Mourning Turned to Joy.

Only a few weeks ago the bee-keepers indulged in a mournful song, now that song has turned to joy, as may be seen by looking over the letters in this issue of the BEE JOURNAL. The present indications are that the honey harvest of this year will be exceedingly bountiful. Now is the time to give every moment to the bees, and see that everything is in order, and that all manipulations are attended to promptly. It will pay well to do so. The *Indiana Farmer* remarks as follows:

The heart of the bee-keeper is glad in the land. Colonies that have cast a swarm will require looking after at frequent intervals to see that the young queen is not lost on her bridal trip. Do not neglect them, then, after she gets lost. With no eggs from which to rear a queen, the colony dwindles away. All sections should be removed from the hives just as soon as they are capped over, thus preserving the pearly whiteness of the capping. If left standing on the hives, the bees soon soil the combs by traveling over them. Honey thus early removed is not thoroughly ripened, and should be placed in a warm place. It is not necessary to wait until every cell is capped over, for the bees will continue to find a place for a cell or two long after the section is sufficiently full to be removed.

By the *Canadian Farmer* we learn that the National Bee-Keepers' Convention has been appointed to be held at Toronto, Canada, during the third week of September—probably on Wednesday, Thursday and Friday, Sept. 18 to 20; but so far we have had no official notice of it, and, therefore, presume that it is not yet fully determined upon.

King-Birds as Bee Enemies.

Mr. Wm. M. Slater, writes thus: "MR. EDITOR.—The following article I noticed in the *Pittsburgh Stockman*, please investigate and report in the BEE JOURNAL."

It is a remarkable fact that all the experts on bee-culture have overlooked the prime laws of all the trouble, and that is by simply letting the king-bird have his way while he makes a perfect fraud of all the Yankee bee appliances, and even the Ohio bee journal itself. On Monday, May 1, my colony was attacked by seven king-birds, and I went to shooting them, but did not succeed in getting all in until Wednesday evening, and in that short time they had got very nearly one-half of my bees, and in despoiling them I found nothing else but bees. Their formation is the same as a duck; they have no craw, and everything they swallow passes direct to the gizzard, consequently requiring double the amount of food of common birds. You can see him all day, perched on fence stakes, stumps or mullon stalks, waiting for the industrious bee, and if it gets within any reasonable distance of him, it is gone. I have seen him dart up in the air nearly 100 feet and catch a heavy laden bee going home. I have seen him dart from his perch and catch four bees and return to his perch, when he would most ingeniously put his bill down to the perch and then take his long middle toe and hold them fast while he would pick off the head and shoulders and throw them away, and swallow the bottle ends, and in ten seconds of time he is ready for another haul.

I am paying the boys 10 cents apiece for all they fetch me, dead or alive. Every bee-keeper knows that bees are divided into two squads, and for convenience we will name one the field hands, and the other the colony hands. Now let the king-birds pick off the field hands, and then the colony hands have got nothing to do, and they go to playing; then we call them idle, lazy bees, and are doing no good, and never for one moment think of the king bird being the prime cause of all the trouble. J. R. A.

The *Stockman* has been imposed upon. The king-bird has been repeatedly denounced by the BEE JOURNAL as a murderous thief, and a

"shot-gun" is very generally used to wake up the ideas of that "bird," when he visits apiaries, on his destructive mission. Mr. A. is simply trying to play "smart," in papers that know nothing of bee-culture, and are therefore unable to detect his false accusations against the bee papers.

Wonderful Instinct in Bees.

Many interesting accounts have been written of the wonderful instincts of honey bees, some, in fact, which would almost tend to prove that they possessed reasoning faculties. An Australian bee-keeper contributes to the *Queenslander* the following interesting incident, illustrative of their sagacity:

A neighbor of mine who keeps bees in bar-frame hives, had robbed them of some of their surplus stores, but noticing a few days afterwards the honey running from the entrance to the hive, and the bees clogged with it, he raised the top to ascertain the cause, when he found the bees in so woful a plight that he knew not what to do, and was quite disheartened. He mentioned the matter to me, and I went to his assistance. I found the hive in a dreadful state; the frames were very large, and the weight of honey proportionally great; the combs had fallen down, and the honey been set free. Thousands of bees were suffocated and smeared with the honey, and it was a work of some difficulty to set matters right. On the floor of the hive, and floating in the escaped honey, were dozens of white grubs, which had evidently been forcibly drawn from the cells by the bees, and the reason they sacrificed their progeny appears to be that, finding themselves overwhelmed with the disaster that had fallen upon them, and having filled every available crevice with the over-flowed honey, they had found it necessary to empty the cells of the young brood in order to find space to store the balance until the wreck could be repaired. There was reason, certainly, for what they did, and the fact has not, perhaps, been noticed before, because the people who kept bees for observatory purposes, would never have allowed such a calamity to happen to them.

What is the Langstroth Hive?

Our attention has been called particularly to the above question by the following argument by Mr. G. M. Doolittle, Borodino, N. Y., against the adoption of a "standard size of frame" for America. At first he starts off as an eloquent advocate of the Langstroth frame, taking broad grounds, including "nearly all the frames in use in the United States" in the term "Langstroth frames." Then, gradually, forgetting his eloquent beginning, he narrows his views down to the idea that *only* those whose dimensions are $17\frac{3}{8} \times 9\frac{1}{8}$ should, in fact, be called "Langstroth frames." But we will not forestall his arguments. Here they are:

There seems to be much written, of late, regarding the Langstroth frame, and I see there is a tendency on the part of those writing on this subject, to classify all frames that are not $17\frac{3}{8} \times 9\frac{1}{8}$ as other than the Langstroth frame. Now I claim that nearly all (if not quite) of the frames in use in the United States, to-day, are Langstroth frames, to all intents and purposes, and I would here say that whether I use a frame 10 inches square, or one 9×13 , all honor is due Mr. Langstroth for giving us a *practical* frame that each can adopt to suit their climate or fancy.

Because I adopt the form used by E. Gallup, it does not make it any the less a Langstroth frame. Mr. Gallup told us, years ago, in the good old AMERICAN BEE JOURNAL, that he considered the frame he used the Langstroth frame, but that he had varied the dimensions of it so as to suit Elisha Gallup and the cold climate of Wisconsin and Iowa.

That Mr. Langstroth himself considered all frames in use embodying his principle, as the Langstroth frame, is proven where he says, "Mr. Quinby prefers to make my frames longer and deeper." Hence it is no more than right that we give Mr. Langstroth the credit of the frame, no matter how far from the original we may have varied the dimensions.

Then again, I notice that some are disposed to try to compel all to use the standard Langstroth frame. This, I think, can never be done, and I see no necessity for it, unless it is to favor the supply dealers. If the supply dealer cannot live at the supply business as it is, perhaps it would be well for him to try apiculture in a more practical way, by getting his "bread and butter" from the honey he is able to produce.

Why I do not believe that the $17\frac{3}{8} \times 9\frac{1}{8}$ inch frame can ever become a standard, is because we will not all give up our views and notions regarding our frames, to adopt the views cherished by others. We see by the last few numbers of the BEE JOURNAL that there is no prospect of Mr. Heddon and Mr. Alves even reconciling the difference of $\frac{1}{4}$ of an inch, and

if two, who are so near a standard, will not make an alteration of $\frac{1}{4}$ inch for the sake of a standard frame, how can it be expected that those using a frame as shallow as the Bingham, or as large as the Quinby, can ever be brought to unite on one frame?

When I first began bee-keeping, I started with the Langstroth frame as given in his book, but after three years, I adopted the Gallup, and am better pleased with it to-day than I was when I first adopted it, for the reason that, after handling various frames, I am confident that I can make more money from my bees, taking all things into consideration, than I could by the use of any other style of the Langstroth frame. However, I once said, and so say now, that had I 30 colonies of bees in hives containing any of the frames now before the public, which are practical, I would not go through the operation of changing all fixtures, for the difference it would make as regards producing honey for market.

Most of the frames now in use are practically good enough for the production of honey, and were all men half as enthusiastic over qualifying themselves to be first-class, practical managers of an apiary, as some are over a standard frame, our production of honey in the United States would be doubled; no matter what frame was used.

As I said before, I prefer the Gallup size of the Langstroth frame, but I wish it understood that I believe the manager has more to do with the securing of a good crop of honey than has the style of frame.

Again, I notice that nearly all who advocate a standard frame, are men claiming to use a frame $17\frac{3}{8}$ or $17\frac{3}{8} \times 9\frac{1}{8}$. Now, if these are valid reasons why I should adopt a frame $17\frac{3}{8} \times 9\frac{1}{8}$, I have failed to see them, and it rather looks as if these men who are clamorous for that frame, are not satisfied with it, or else have some selfish point in view.

Once more, Mr. Porter tells us, on page 288, that one reason why we should adopt the Langstroth frame is, that the *returns* are greater than from other styles; and winds up by saying that "Doolittle comes the nearest to it, but I forget the dimensions of his frame. But he has been greatly surpassed." Who by? Lots using the Langstroth frame. Admitted; but who surpassed the lots? L. C. Root with the Quinby frame. Does this help Mr. Porter any? Then, Mr. Pond says (not in the BEE JOURNAL), in trying to sustain the merits of the $17\frac{3}{8} \times 9\frac{1}{8}$ frame, that Doolittle winters bees poorly, while a certain man using the Quinby frame winters every time. Again, I ask does this help the Langstroth frame any? Where does A. I. Root and J. Heddon stand regarding successful wintering as a plea for your lauded style of frame. Another thing, let me just whisper, if I am correctly informed, that persons said to have wintered bees with his Quinby frame every time, has brought more bees in the spring (since I kept bees) to replace his loss than Doolittle ever owned.

Just one more point and I have done. A. I. Root often tells us, in *Gleanings*, that there are more Langstroth hives and frames in use than of all others put together (I saw a report of a convention not long ago, where but two used that frame out of 13 of our largest bee-keepers, which did not look as if Mr. Root's assertion would stand the proof), but for the sake of argument I will admit that there are. Now, I ask Mr. Root, in all candor, how came such a state of affairs to be brought about? Was it not because he had machinery all rigged to turn out the Langstroth hive, and then told all, through *Gleanings*, that all ordering the Langstroth hive and fixtures for it, would get "the regular goods" at once, while if they wished odd sizes their orders must be delayed till the others were filled. And did he not tell all the beginners that they should fall into (that) line? Now, if Prof. Cook had edited *Gleanings*, and been as strenuous for the Gallup frame as Mr. Root has been for the Langstroth frame, and L. C. Root had been editor of the BEE JOURNAL, and was pleading for the Quinby frame, would the Langstroth frame been in the ascendancy? I trow not!

I am willing that any one in the world should use a frame $17\frac{3}{8} \times 9\frac{1}{8}$, if they so desire, but I *do* like to see the advocates of such a frame come out *square* and *honest* before the world, and let the people know the whole truth regarding what caused the state of affairs, which now exist.

Borodino, N. Y., June 11, 1883.

Mr. Doolittle is quite unfortunate in the latter part of his argument. At first, he claimed that "nearly all (if not quite) of the frames in use in the United States, to-day, are Langstroth frames, to all intents and purposes"—the principle and not the size, being the distinctive feature of this deservedly-popular frame.

Then towards the close he chides Mr. A. I. Root for claiming "that there are more Langstroth hives and frames in use than of all others put together," notwithstanding that Mr. Doolittle had made a more sweeping assertion even than that, in the first paragraph of his argument.

This shows that Mr. Doolittle is *not quite clear* about what the distinctive feature of the Langstroth frame is! or, perhaps, he became so *bewildered* by the magnitude of his own argument, that he lost his balance, and *tumbled* to the other side of the question.

His assertion is doubtless true as given in the first paragraph—but, this admitted, proves also that Mr. A. I. Root is correct in his assertion, which Mr. Doolittle chides him for making! There is no escaping this conclusion!

Prof. A. J. Cook also takes the same view of the matter. In his

Manual he eulogizes the Langstroth hive and frame, and then adds: "Though I prefer and use the *size* of frame first used, I believe, by Mr. Gallup, *still I use the Langstroth hive.*"

Mr. M. Quinby also entertained the same ideas. In Quinby's New Bee-Keeping, page 97, Mr. L. C. Root, its author, says: "In the previous revision of this work, in 1865, Mr. Quinby fully recognized the merits of Mr. Langstroth's invention, and described the *modified form of his hive.*" This modified form was called the "Quinby;" Prof. Cook's "varied size" of it, is called the "Gallup;" Mr. King's variation was named the "American," and other modifications bear names by which to designate the varied size of the Langstroth frame and hive. Hence, Mr. Doolittle was particularly correct in his first paragraph, in stating that "nearly all the frames in use in the United States to-day are Langstroth frames."

As to the desirability of having the sizes in use as *few* as possible, there can be no two opinions. With the sizes used by Quinby, A. I. Root, King, Gallup, etc., there certainly are enough for all climates, and the practice of varying the sizes of any of these, just a little, to suit a notion, is very reprehensible. The variations made by Mr. A. I. Root, from 17 $\frac{3}{8}$ to 17 $\frac{5}{8}$ we regard as an exception, because it was done to accommodate the use of the one-pound sections in cases in the brood-chamber, interchangeably with brood frames. If all cannot unite on one size, all *can* unite in agreeing to use *one* of the standard sizes before enumerated.

Another point made by Mr. Doolittle is quite correct—more depends on the management than on the size of the frame used. This we have so often argued and asserted, that it is not now necessary to do more than to endorse most unreservedly Mr. Doolittle's statement.

We grant that, for convenience, the size 17 $\frac{3}{8}$ x19 $\frac{1}{8}$ is usually called the Langstroth to distinguish its *size*—but when we indulge in an article on the movable frame principle, they are all to be included in the same class.

Hence, it is clear that even if (as Mr. Doolittle agrees) Prof. Cook had been editor of *Gleanings*, and Mr. L. C. Root had occupied the editorial chair of the BEE JOURNAL, even then, the deduction made by Mr. Doolittle is *totally unwarranted*, viz.: that the Langstroth frame would *not* have been in the ascendancy! Prof. Cook

and Mr. L. C. Root both claim to use the Langstroth frame in a modified form, and hence they would have advocated its use—and it would "have been in the ascendancy," even though the size may have been a little varied, one way or the other!

The Order of the Honey Bee.

In an interesting notice on French orders of Chivalry, past and present, a writer in the *Journal des Debats* mentions, among many other extinct Orders, the "Order of the Honey Bee," and gives the following very interesting scrap of its curious history:

The last named has a curious history. The medal of the order had on one side a hive with the motto, "Picolasi, ma fa pur gravi le ferite," (Small, no doubt; but it inflicts a sharp wound), while upon the reverse were the head of the Duchess du Maine and the following inscription in capital letters, "Anne Marie Louise, Barrone de Seceaux, dereciterice perpetuelle de l. Ordre de la Mouche-e-Miel," underneath, "Seceaux, 11 Juin, 1701."

This was the date of the foundation of the order by the Duchess du Maine, a grand daughter of the famous Prince du Conde, whose husband purchased the Chateau de Seceaux in 1700. The duchess, who was very fond of amusements and ceremonial, made Seceaux the rendezvous of the most brilliant wits of the day, and in 1703, she instituted the order of chivalry, to which the youth of both sexes, were eligible.

The members of the order were expected to appear at the entertainments given at Seceaux, the men wearing a tight fitting costume of cloth of gold sprinkled with silver bees, and a head-dress made to imitate a hive, while the costumes of the ladies consisted of a dress of green satin embroidered with silver bees, a mantle of cloth of gold, and a diadem formed of emerald bees. The oath of fidelity which had to be taken by each new member was as follows: "I swear, by the bees of Mount Hymetus, fidelity and obedience to the perpetual mistress of the order, to wear all my life long the medal of the bee, and to comply to the statutes of the said order. If I am found false to my oath, may the honey turn to venom, the wax to tallow, the flowers to nettles and may hornets and wasps sting my face."

After her husband's death, the duchess did not name any fresh members; but when conversing with Fontenelle, who, together with Voltaire, Marivaux, and other wits of the time, used to visit her at Seceaux, she expressed her regret that he had not been among her earlier friends, as she would have liked to have conferred her order upon him.

Fontenelle remarked that he would have been ill at ease with a hive on his head, as it must have been very much in the way of the chevalier and

of the flower about which he was flirting. To which the duchess rejoined, "Not so much as you may imagine; for surely the flowers bend down to the kiss of the bees."

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL.
Monday, 10 a. m., June 25, 1882.

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY.—The nominal price of extracted is 7c. for dark and 3c. for light—here. The supply is abundant and sales are slow.

BEESWAX.—None in the market.

A. L. H. NEWMAN, 323 W. Madison St.

CINCINNATI.

HONEY.—The market for extracted honey is lively, and the demand exceeds the arrivals. Our stock is small and we are in danger of having sold out every day. We pay 7c. 1/2c. for good honey on arrival, the latter price for choice clover. There is a small demand for comb honey, and prices nominal.

BEESWAX.—Arrivals of beeswax are plentiful. We pay 35c. for a good article on arrival.

CHAS. F. MUTH.

Quotations of Commission Merchants.

NEW YORK.

HONEY.—Best clover in 1-lb. sections (no glass) 22c. 2/3c.; in 2-lb. sections (glassed) 18c. 2/3c. Fair quality, 1 and 2-lb. sections, 17c. 1/2c. Extracted, white, in small barrels, 19c. 1/2c.; buckwheat, 8c. 1/2c. BEESWAX.—Is more plentiful. Prime yellow sells at 37c. 3/4c.

J. L. K. & F. B. THURBER & Co.

CHICAGO.

HONEY.—Prices declining. Holders are anxious to sell, and the prices vary very much.

BEESWAX.—35c. 3/4c.

R. A. BARNETT, 161 South Water St.

SAN FRANCISCO.

HONEY.—Nearly 300 cases new, mostly extracted, arrived per Southern steamer on Monday, June 15. Sales of part of the same in a wholesale way were made at 6c. Retail transfers were made at a little higher figure. Quotations for comb are nominal. There is a little choice new comb offering, but no sales reported. One buyer offered 12c. for six cases, but insisted on being allowed about 3 lbs. extra tare. White comb, new crop, 12c. 1/2c. Extracted, choice new, 6c. 7/8c.

BEESWAX.—Wholesale, 27c. 2/3c.

STEAKS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY.—Strained salable at 6c. 7/8c.; combs sold in a jobbing way only—old 10c. 1/2c., and new 15c.

BEESWAX.—Sold mainly at 33 cents—latter for prime.

W. T. ANDERSON & Co., 117 N. Main Street.

CLEVELAND.

HONEY.—There is a moderate sale for best white 1-lb. sections at 18c. occasionally 19c., but 2-lbs. are not called for. Extracted is no sale at all.

BEESWAX.—Not offering.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY.—Our market is fairly active. We quote: 1/2 lb. sections at 30c.; 1 lb. sections, 22c. 2/3c.; 2 lb. sections, 20c. 2/3c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.

BEESWAX.—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatham Street.

The bee-keepers of Fulton and adjoining counties, are requested to meet at the Commercial House, in Astoria, Fulton, Co., Ill., on Saturday, June 30, at 2 p. m., for the purpose of organizing the Fulton County Bee-Keepers Association. By order, COMMITTEE.

Preparation of Honey for the Market.—including the production and care of both comb and extracted honey, instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

CORRESPONDENCE

For the American Bee Journal.

Separators or no Separators.

L. C. WHITING.

Can we dispense with them? This question must be answered by each bee-keeper for himself. If he has only a few colonies, and expects to sell his honey to his neighbors, he may get more honey with less labor without separators; but when he has to go into the market and compete with others, the straight combs and well cleaned sections, well crated, will sell first at a remunerative price.

I experimented with a few colonies last season, and out of 700 pounds stored without separators, at least 100 pounds was so bulged that it could not be crated, and much of the balance had to be worked in with that stored with separators.

To get rid of this 100 pounds cost me more time than five times the amount of straight combs.

Some of our merchants bought a lot of honey in the cap, just as the bees stored it without separators. They did not know how to get it out; they pulled the tops of some off in doing so. Many sections were attached more or less to others, and honey was on every thing. The bees soon found it out, and made it lively for a time. The result was that they did not care for honey, especially in that shape.

One of our best bee-keepers, a few days since, said if had only honey put up in that shape to compete with, he should be sure of his success.

The way that suits me the best is, to put on a part of the sections at first without any separators. After the bees have these well started, divide them, putting a part in each row of sections, and put in the separators. This induces the bees to work in each row of sections. I also change partly filled sections, bees and all, to other colonies, if they are slow in entering the sections. If the flow of honey continues, they are almost sure to work in the sections and leave the room below for brood. One of my neighbors, who has great success in getting a large yield of honey in sections, does not use the extractors, but changes the brood combs, putting those filled with honey in the centre of the hive, and the uncapped brood to the outside, and changing it back to the centre when it is ready to hatch, always keeping open brood in the outside combs.

He certainly has strong colonies, and secures a large yield of honey. Success in all these manipulations depends largely on the good judgment of the bee-keeper. "The right thing at the right time," is what is wanted. The queen, during the flow of honey, should have no more brood combs than she can keep full of brood and eggs.

East Saginaw, Mich., May 26, 1883.

For the American Bee Journal.

Fastening Comb Foundation.

J. S. DUNCAN.

After trying many of the various methods of fastening comb foundation in sections, that has been described in the BEE JOURNAL, they being slow and tedious, and not suiting me, I have constructed a fastener that has worked with perfect satisfaction, and will try and describe it so that others can make one.

It is constructed as follows: A board about 7x12, with holes mortised near the centre, 3 inches apart; two standards are tenoned to fit these mortises, and wedged tightly. The front or presser standard is 3 inches high; the lever standard 2 inches high. These standards are dovetailed on top, and have holes bored for joints of levers; two levers are fitted to these dovetails and fastened with bolts; one lever 9 inches long, and a hole 2 inches from one end; one lever 5 inches long, and a hole in the centre, and a tenon on one end to take the presser, the long lever fitted to the short standard and applied under the end of the short lever; a rubber band or spring, from the board to the

Comb Foundation Fastener.

short lever, brings it back to place, when the pressure is removed. The presser is 3x4 inches (or any size to suit the section used), with a hole mortised near one side, and fastened on tenon, with a pin, and so fitted that when a two-inch section is under the presser and gauged against the standard, the presser will strike about $\frac{3}{8}$ on the section, or so that the foundation will hang in the centre of the section when inverted. The bottom of the presser being rounded so as not to cut the foundation, and made of soft wood to hold moisture. In using grooved sections, place the foundation just over the groove; press slightly, to make it stick; slide under the presser, till the section strikes the standard; press on the lever and the job is done. I prefer sections not grooved; in using them, make a foundation gauge with two pieces of sections; one projecting over the other, and tacked to a board; slide the section under the projection, and lay on the foundation to the gauge.

This press is very convenient, as it requires no clamps or screws to fasten it to the table, as the pressure is applied at both ends at the same time. With this machine you can fasten foundation just as fast as you can handle the sections. The foundation sticks best when it is firm enough to handle good, and is not soft; keep the presser well wet with

soap water or honey, and you can fasten 50 starters without any sticking. A piece of tin, with the edges folded up, and several folds of cloth in it, makes a good pad for wetting the presser.

Browning, Mo., June 12, 1883.

Read at the Maine Bee-Keepers' Association.

Spring Management of Bees.

H. E. CHAPMAN.

In presenting this paper, I shall endeavor to give only an outline of the subject, for, if I should go into all the points and particulars, it would take too much time; besides I do not feel capable.

In a well managed apiary, spring management will include 3 months—April May and June. If bees are properly cared for in the fall, they will need but little attention before April. Examine all your bees the first warm day in April, to see if they have sufficient stores. I would not advise having much honey in the center at this time of the year, as the queen will be crowded for room. The two middle combs should be empty, or nearly so, and if the bees go into winter quarters as strong as they should, such will be the case. If any colonies are found short in stores, give them a comb of honey saved the fall before, or sugar. Take away all unnecessary combs, confining the bees on as few as they can cover. Make the entrance small; many leave it open the whole width; this is wrong. What would you think of a man who insisted on having a door half the width of his house and twice as high as his head, and open all the time? Bees must be kept warm during the chilly weather of spring. Examine your locality to see when the flowers blossom that produce an abundance of honey, then have every colony in the best working condition possible; to accomplish this, feeding should be resorted to.

Outdoor feeding is preferable if you are not troubled with other people's bees, but if you are, then feed in the hive. Maple syrup has proved excellent for out-door feeding, as it does not stimulate robbing. To start them to work on it, put a little honey on the feeder, and it will make you laugh to see the little fellows carry it off. Keep the feeders full; the bees will not carry off more than they want. If you wish to feed in the hive, place two strips three-eighths thick upon the feeder; in this cover, insert a tube made of wood—place the feeder across the ends of the frames, then lay on your quilt and chaff, and it is ready for use. I do not like sugar candy for feed, as the bees will tear down and carry out a large part of it.

When the combs become well filled with brood, they should be spread and an empty comb inserted, taking care not to spread too fast. Every colony should have a good laying queen. Quinby said, "The introduction of a mature fertile queen to a colony two weeks sooner than when they swarm naturally, is an advantage sufficient to pay for the extra trouble.

The time gained in breeding, is equivalent to a swarm." If such is the case, it will pay well to buy queens. When the brood chamber is well filled with brood, and the young bees begin to hatch rapidly, put on one tier of boxes.

I think a few pounds of sugar syrup fed at night after the boxes are placed on, will give much aid in starting them in. The swarming season demands the close and prolonged attention of the bee-keeper, hives, boxes, frames, and feed should all be ready. The new hives containing comb or comb foundation, should be placed upon the stands where they are to remain through the summer. If natural swarming is followed. Do not give your new swarms too many frames of foundation or combs; the best results will be obtained with five or six frames. If honey is coming in well, put on one tier of boxes within 12 hours after swarming; when these are three-quarters full, raise them up, putting under another set.

If you have a colony rounding off the corners of the combs before the boxes are plump full, they think they have done enough, and the best way to keep them at work is to make an artificial swarm from them. It requires a very clear mind to keep the bees profitably at work all of the time.

For the American Bee Journal.

Management of Bees in the Spring.

ALLEN PRINGLE.

The past winter and spring has been the hardest season on bees, in this latitude, I have ever witnessed. Upon making diligent inquiry within an area of many miles in the eastern counties of Ontario, I find that of the bees wintered outside without protection, almost all are dead; of those protected outside, two-thirds are dead; and of those wintered in bee-houses and cellars, on an average, one-half.

To those who wintered their bees properly indoors, the spring has been much worse, and more fatal than the winter. It has been exceedingly unfavorable up to about the first of June. Indeed, some of mine are still protected with extra warm stuffed quilts. The fruit bloom was only at its height two or three days ago (8th); is fully two weeks behind other years, and almost everything else proportionally backward. The corn was only planted, in this locality, the past week, and the potatoes are yet to plant.

My own bees were taken out of winter quarters about the first of April, in very good condition; all alive. I have since lost two colonies by dysentery or "spring dwindling," and two, whose queens were accidentally lost just after being put out. But I certainly would have lost two-thirds of my stock of bees had I not stirred my wits to circumvent the most unpropitious weather, and fight against most adverse circumstances. When old bees are set out in the

spring, and begin to exercise on the wing, their pilgrimage in this world is exceedingly short; and unless you can, in spite of the frowning and unfriendly elements, promptly induce the breeding of young bees to take the place of the old ones, your hives soon become still—not the stillness of snug winter quarters, but the stillness of death.

Now, according to my experience, the best way to accomplish this purpose—to induce sufficient breeding to preserve the colony—is this: Keep them warm from the time you set them out; and after their cleansing flight, the very first day warm enough to open the hives, examine them, thoroughly clean out the dead bees, etc., and diminish their room according to their strength, crowding very weak ones up on two or even one frame, and others into three, four or more frames, according to strength. The next thing to be done is to keep them warm, by extra quilts on top, and keeping the entrances closed, except when it is warm enough for the bees to come out. The next thing is to feed them a little honey, or good syrup, every day, in the evening; and, whether there is natural pollen to be had outside or not, give them the artificial article inside the hive, in the shape of cakes rich in nitrogen and soaked in honey. This regime with other little matters which the common-sense of every experienced bee-keeper may suggest, will carry the bees through adverse spring seasons if anything will.

One or two other important matters occur to me which I will also mention: Sometimes, even after the bees have had a cleansing flight, if the weather is such that they cannot get out for many consecutive days (as happened two or three times this spring), they will become badly afflicted with the dysentery. In such cases, I give them a little carbolic acid in their honey, or in their cakes, with uniformly good results. The other point occurring to me is this: After you begin the stimulation of feeding in the spring, the old bees are much more apt to venture out in unsuitable weather; and in high cold winds they are lost, and never get back. It is, therefore, expedient to be on the look out, and shut them in during such weather. In many cases it would be better to carry the bees back to the cellar or other winter quarters, after they have had their flight, then to entice them outside by feeding, only to be lost.

The intelligent apiarist must use his own judgment and govern himself accordingly; and, above all things, he must watch his bees and not neglect them. As you are passing that way, it may be to other work, take a look at your bees, for you may see something wrong—something needing your attention. In bee-keeping, as in other things, "eternal vigilance" is the price of success.

The prospects here for an abundant honey harvest are excellent; indeed, almost unprecedented, so far as we can recollect. Clover of all kinds has come out this spring in a better

condition than I ever saw it before; and the fruit bloom is proverbially exuberant. The trouble is, however, that bees generally are not yet strong enough to take advantage of the abundant fruit bloom. It will take to near the end of this month to get them thoroughly built up. Meanwhile, during the interval between the fruit bloom and white clover, I would suggest to the inexperienced bee-keeper the wisdom of feeding his bees a little every day, to keep up the strengthening process now going on.

Selby, Ontario, June 11, 1881.

For the American Bee Journal.

The Rearing of Queens.

E. A. THOMAS.

Having received several inquiries regarding my method of rearing queens, I will now give a description of it. The ground work of my method is doubtless familiar to the reader, and I shall, therefore, give more attention to the smaller points which many consider of but little consequence, but which I consider all important, and to which I attribute much of my success in queen-rearing.

I commence operations by hanging in a clean comb into the colony which I wish to breed from; this colony must be strong and vigorous. Having several breeding queens, I use the strongest one first. Several days previous to hanging in the comb, I begin feeding the colony and continue to do so until I obtain the eggs. I crowd the brood nest together as much as possible, removing all empty combs, so that the queen must lay in the comb prepared, if she lays at all. In this way I get a frame filled with eggs in a very short space of time, the advantage of which will appear further on. At the same time that I hang in the empty comb into the first colony, I deprive another strong one of its queen, at the same time commencing stimulative feeding, and by the time the eggs are ready, they are in the best possible condition for building cells. I then deprive this colony of all unsealed brood. Taking the comb of eggs, I cut out strips, about an inch wide, from top to bottom, leaving two inches of comb between; these I fit into other empty frames of comb, fitting them in diagonally, cutting out about an inch of comb under each piece. These frames I hang in the center of the hive prepared to receive them, and continue feeding them as before. When it is time for the cells to be sealed over, I examine the combs, and all cells that are just started and not sealed over, I cut off; and it is to this fact that I attribute much of my success. All the eggs being laid at very near the same time, I can tell just when the cells ought to be sealed over, if started from the egg when it first hatches.

After this time, all unsealed cells must have been started late from larvae, and therefore are destroyed. This is how I get my cells started from the egg when it first hatches.

The reader cannot fail to appreciate the fact that, placing a comb of eggs in a colony, will not insure all the cells started from the egg or young larvae, as bees will continue to start cells until the larvae gets too large to develop into queens; but by knowing when the first cells ought to be sealed over, and destroying all after cells, we are sure of obtaining what we desire, viz: queens reared from larvae, fed, from the time they hatch from the egg, upon the royal jelly.

I let the cells remain in the colony where they were reared, until nearly ready to hatch, and here is the advantage of having the eggs laid at nearly the same time, as it enables me to tell, within a few hours, when the cells will hatch. When nearly ready to hatch, I cut them out carefully and insert in the nuclei, cutting out enough comb with each cell to be sure and not press the cell in any way. Nuclei will very rarely destroy cells when just ready to hatch, even if put in soon after their queens are taken from them, and I am seldom troubled with loss of queens in this way.

As soon as each queen hatches, I hunt her up and examine her carefully, to see that she is all right. If there is anything about her that is not perfect, her head gets between my thumb and finger. I save only the perfect ones, as I want no others.

Now how do I mate my queens? I will tell you. I select early in the season a number of colonies which produce the best drones, and keep them continually stimulated by feeding, and give them all the drone comb they will use. These colonies will, therefore, rear an immense number of drones, and by keeping the drones in the other hives cut off, I reduce the danger of mating with poor drones to a minimum.

To some, my method of queen rearing may seem laborious, with too much attention given to small matters, but it takes labor, time and attention to small matters, to rear good queens.

Another important element to success, is care and skill in selection. I aim, in selecting, to combine all the characteristics of a good strain of bees, breeding from beautiful, prolific mothers, and rearing drones from the most hardy and industrious colonies. Such a queen, mating with such a drone, cannot fail to produce fine offspring. And by continual selection from each generation, I am all the time raising my bees to a higher standard of excellence.

Preparing for Winter.

L. R. JACKSON.

Successful wintering of bees, in the North, is one of the most important subjects with bee-keepers. This, I think, is any easy thing to do, if we commence in time to prepare for the coming winter. I have always commenced in June to prepare for winter, and have always been successful in my 8 years experience, having never

been troubled with "spring dwindling" but one year, and that was when I fed the bees with rye flour early in the spring.

Honey contains sugar in two forms: Cane sugar and grape sugar. Clover honey contains more cane sugar than fall honey, and is more easily and more thoroughly digested than grape sugar, or fall honey, and should be used for winter stores.

Our bees now have honey enough to winter them, with all the increase we shall have, and, as soon as it is well ripened, we will put away 2,000 pounds for winter. Then we can take honey with no fear of our bees starving next winter.

I have never known as good a prospect for a large crop of honey as we have this year, or known bees in a better condition for gathering it than they are now. Nearly all our bees are working on 20 Langstroth frames, and are crowding the queen, in spite of all we can do, unless we extract the honey before it is ripe, which it will not pay to do.

We have rain about three days in the week, yet it does not seem to stop the flow of honey as it usually does. I had prepared to run the bees for increase until I saw what the harvest was going to be, when I changed my plans, and it has crowded me with work, so that I have had to hire extra help, and work from 4 a. m. until 8 p. m. to keep up with the bees.

I have given a few hints for wintering, which can be understood by any who wish to profit by them, and in September I will give my plans for packing.

Urmerville, Ind., June 11, 1883.

For the American Bee Journal.

Honey Plants of Louisiana.

J. A. SMYTHE.

I see by a late copy of the BEE JOURNAL, that apiculturists, in general, have the blues; in this section we are all trying to excell each other in blueness. The spring was very late, and was followed by cold rains.

Most of us made our increase during March and April, while the willow and oak trees were in bloom; since then, bees have not gathered enough to support themselves. Our bees all have to cross a lake a mile wide, to a willow bank, for their principal supply of honey; the contrary winds and cold rains have caused thousands of them to fall into the water to rise no more. As June, July and August are our great honey months, and as no one has taken honey yet, most of us have lost all hope of making more than expenses. One of my neighbors, who has nearly 400 hives, has spent \$500 upon them, this year, in improvements; he does not even expect to make expenses.

For the benefit of Northern readers, I give a list of our best honey plants with date of commencing and end of bloom. It is the result of two years observation, and is generally accepted in this section. Plum, apple and peach, from Feb. 1 to 27. Willow,

Feb. 1 to April 10. Oak, March 15 to April 1. Orange and China trees commence blooming March 15 and last two or three weeks. Clover and dew-berries bloom in March, but cannot be depended upon. Bees seldom obtain much honey from fruit trees, owing to the cold rains. The willow and oak are our stand-bys. Orange trees are rather scarce; China only yields honey early in the morning.

For the summer months we have corn, elder, sweet bay, crape myrtle and clover, besides countless vines and swamp plants which produce more or less honey. Corn, elder and clover are our best honey plants; bees working upon them all day long; sweet bay only produces honey after a rain; crape myrtle give large quantities some years, while in others it is perfectly barren.

I have seldom seen bees upon cotton, although Prof. A. J. Cook classes it among honey-producing plants.

During the swarming season, our bees (Italians) seldom wait for capped queen-cells before swarming; sometimes swarming without leaving even a sign of a queen-cell.

Hermitage, La., June 11, 1883.

For the American Bee Journal.

Wood Separators.

F. M. REEDS.

I have been waiting for some one to give his experience with Dr. Besse's wood separators, but as none have reported their success or failure with them, I thought I would write a few lines concerning my own failure. I had for sometime, before noticing his article, been reflecting in regard to wooden separators, and, in fact, had sawed out some by hand, which, by the way, is a very particular job, if sawed as thin as should be; but as soon as I saw his article, I thought I had struck a bonanza, for cheap separators; so I sent an order for 350, which were received all right and in due time. But with me, they have proved a complete failure; they having been cut out of green elm, like all elm lumber, warp and twist as soon put in between the boxes, in such a manner as to render their use impossible; and while I do not doubt that the Doctor is still, and has been all the time, honest in his effort to supply the long-needed cheap separator, I have no doubt, in my own mind, that he has made a sad failure; as they are cut out of elm timber. The boards were nicely cut, and would, no doubt, have made fine separators had they been cut of timber which would not warp, and if some one will get them up as nicely as those I received, of some kind of lumber that will not warp, I will try some more, for I believe the day is not far distant when they will be the only separator used. I am now cutting some by hand from pine lumber, which does not warp.

I see a great many notions in regard to deep and shallow frames. Now, I have used two kinds or two widths of combs, 7 and 8 inches, with hives

19 $\frac{3}{4}$ x15 inches, using 10 frames to the hive, and I prefer the 7 inch frame, and am cutting all my combs to that width. I find they are easier to handle, contain an abundance of surface for brood-rearing, with plenty of honey for wintering, and it gives, I think, superior advantages in honey gathering.

The season has been very cold and backward here, up to June; since then, we have had too much rainy weather. White clover is abundant, and bees are doing well, when they can, they work strongly and store some surplus, but are not swarming.

Hinesborough, Ill., June 11, 1883.

For the American Bee Journal.

Antidote for Bee Stings, etc.

E. H. THURSTON, M. D.

The sting of the honey bee makes cowards of many brave, strong men. Were it not for this, the army of bee-keepers would have many new recruits each year. The bees, though small compared with man, but few are willing to meet in combat.

There has been some inquiries for an antidote for the poison of stings. Some bee-keepers laugh at the idea of an antidote, while others make very earnest inquiries for it. I have been experimenting with various articles, and have found, I think, a true antidote. It may not be new to many, but I feel confident, all who are affected by the poison, will appreciate its value. It is carbonate of ammonia. It should be powdered and kept in a tightly-corked bottle. I always carry a small phial of it in my pocket, which I use in my practice. When I receive a sting, I wet the surface over the sting, and apply a small amount of it. The pain is relieved immediately, and it never swells.

I was called a few days ago to see a child, about 3 years old, who, in childish play, put a stick into the entrance of a strong colony of bees. They stung him very badly on the head, face and neck; there were not less than 100 stings. I had him bathed with a strong solution of carbonate of ammonia, and gave him a solution of some of it inwardly. The next day one could not tell that the little fellow had been stung at all.

Did you, Mr. Editor, ever hear of roast chicken as bee feed? We have a box-hive bee-keeper, in this county, who says that every winter he cooks a chicken and puts it in his hives for the bees to feed on; that they eat it all up clean, not leaving anything but clean bones. This is new to me.

Bees are just beginning to work on white clover. May was a hard month on them. The cold, snow and rain prevented them from building up, but they are now doing well.

Hagerstown, Ind., June 9, 1883.

[Yes; we have heard of such before; some cook eggs and puts in the hives; others give them whisky—but all these notions belong to the superstitions of the past, with that of "telling the

bees of a death in the family," and refusing to sell them, because it is *unlucky* to do so, etc.—ED.]

Read before the Texas Convention.

A Few Thoughts on Marketing.

DR. J. P. H. BROWN.

That there is a pleasure associated with the production of an article, whether it be a thing of beauty or something that administers to our health or happiness, cannot be denied. The amateur florist goes into ecstasy as he watches some rare flower bud and unfold its petals and display its gorgeous tints. The fruit culturist glories in the production of a specimen of some rare apple, pear, peach, grape or berry; while the apiculturist prides himself in his bees and in the production of tons of honey. He loves to see the product of his little pets. But aside from the mere pleasure of production, there is probably a greater pleasure to know that we can dispose of the product for dollars and cents, and be thereby rewarded for our labor.

True, the production of honey is much easier than it is to find a market for it, still I am satisfied from my own experience and from the experience of others, that markets can often be made where before there were comparatively none. As a general thing, the nearer home the market is, the better it is for the producer. High freights and commissions are pretty certain to eat up the profits. There is not a town nor village in the South where a trade in honey cannot be established if the proper means are taken to introduce it. There can be no excellence without labor and exertion, and there can be no honey market without the right kind of efforts. Up to within a few years past, our Southern honey went to market in the worst possible condition—mashed and messed along with pollen, dead bees and juicy larvae, in old buckets and tubs, presenting everything but an inviting appearance to the purchaser. Such stuff, instead of inviting the buyer, has a tendency to engender disgust. But with our modern appliances for obtaining honey, there is no longer an excuse for any such badly-conditioned honey to come on the market. It has been pretty well settled by the largest honey producers of our country, that honey put up in small packages sells the most readily, particularly at home markets. Compactness, neatness and attractiveness are essentials to be observed on the part of the producer. Many persons who may at first buy a small package, will soon return and want a larger.

When we cannot sell our honey directly to the consumer, then we have to send it to the middle-man or commission merchant. And right here it should be remembered that not one grocery merchant in fifty knows how to handle honey. The expert salesman, like the expert producer, must have a natural fitness for the position. When a merchant is

willing to undertake it, and displays the necessary tact and ability to introduce the commodity to his customers, the bee-keepers of the neighborhood should sustain him; because there would be a likelihood of his better being able to keep up the price and extend the sales, then if it was put in the hands of half dozen grocerymen of the town to sell at all sorts of prices, and to be offered in all sorts of shapes.

Although honey was one of the first articles of sweetening that man knew anything about, and the exclusive article for thousands of years, still at the present day the majority of people know comparatively nothing of its properties, and the multitudinous uses to which it can be applied. The people should know of its remedial qualities; they should know that it is pure, and the syrup that God prepares in the laboratory of the flower, and that it would be far better to use it in their families to the exclusion of the adulterated and glucosed syrups that breed disease and death. Bee-keepers' wives should go to the conventions, associations and fairs and display their honey-cakes and their honey preserved fruits. This would attract attention, and give honey a prominent place in the culinary art. If bee-keepers were to distribute pamphlets calculated to educate the people upon these questions, great good would result in the increased consumption of honey; and I know of nothing better for this object than a little book entitled: "Honey as Food and Medicine," published by Thomas G. Newman, of the AMERICAN BEE JOURNAL, Chicago, Ill.

When it becomes necessary to ship honey long distances it had always better be extracted, well cured before barreling, put up clean, and the barrels should be secured against leaking. It is very annoying to a honey merchant to find a consignment of honey come in a leaking condition—the car floor covered with it, and a stream of it running across the depot—all owing to the carelessness of the shipper. If bee-keepers desire good markets and good prices for their honey, they must encourage concert of action among themselves, be faithful and vigilant, and offer their product in the neatest, most attractive and secure manner.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Several have asked questions upon the following topics, which I hereby endeavor to answer:

Introducing Queens.

I practice two methods. If I have a very choice one, and wish to take very little risk, I operate as follows: I kill the reigning queen, and put the new one to be introduced into a wire cage between the combs, and after 24 hours I open the hive, and if I see the bees "balling" the cage (that is, 2 and 3 deep upon it, savagely trying to force an entrance), I close the hive for 24 hours more, and so on till I see the bees crawling over the cage in an unirritated manner, then I pull the stopper to the cage, the open end placed close to the entrance, and with smoker in hand, smoke the queen in, and smoke the bees, by pulling right in after her.

If the queen is of only ordinary value, I smoke her right in without any of the previous caging. I have had almost uniform success with the latter method, what little I have used it. Two points of caution are in order. Never introduce any workers with the queen—just the queen *alone*. Never open or otherwise disturb the colony under five days from the date of introduction.

Using Comb Foundation.

In using comb foundation I always use it in full sheets above and below. Any person who has ever used a Parker foundation fastener, will never mention melted wax or any thing of the sort. Next to the Parker fastener is a good strong putty knife. Beeswax at a temperature of about 100° can be mashed on to smooth wood much firmer than it can be melted on.

Good comb foundation, to use in brood frames and sections, is worth to the user \$2 or \$3 per pound. As guides and starters it is worth more than \$5 per pound, which, if granted, shows how much they lose who fail to use it in *full sheets*, and how much more they lose who do not use it at all.

One word of caution here too. Never fail to use foundation, full size, in sections resting upon a hive

that has all worker combs below. If you do, and thus give the bees a chance to build drone comb in the sections (one that they will surely improve), there being no chance for drone brood below, you will be almost sure to be annoyed with it there.

Capping Honey, Ants, Feeding, etc.

1. Please tell me what I can do to make my bees cap their comb? They are drawn out, until they are all out of shape and joined to the separators. What can I do to make them cap it?

2. Will salt, to keep off ants, injure the bees at all?

3. Shall I feed any now, in New England States? I am a beginner, so please answer questions which seem simple to others, but not to me.

HELEN L. RICHARDS.

Longwood, Mass., June 15, 1883.

1. Never having seen such a case, where all was normal, I can hardly tell you how to proceed. I think if I knew *all* the conditions, I could advise what to do.

2. No; it will not injure bees; and, I fear, not keep off the ants either.

3. I would advise you not to feed except at times when stores are needed to prevent starvation. Such can hardly be the case with you, after the date of your question.

Where is the Old Queen?

On April 10, 1883, my Italian colony No. 1 swarmed, and I hived the swarm in hive No. 2. Colony No. 1 has swarmed twice since; I put them in hives No. 3 and 4, as they came off. Now, colony No. 2 has swarmed twice also, which I put in hives No. 5 and 6 as they came off. What I wish to know (as I am an A B C scholar), where is my old queen? As she is very prolific, I wish to rear queens from her to Italianize my blacks with, as I think it probable that the young queens became fertilized by my black or hybrid drones. Colonies No. 3, 4 and 5 will, from present indications, swarm in a few days. The gentleman whom I bought my hive of Italians No. 1 from, last year, had only 2 colonies, in the spring of 1882, which were in patent hives, and they were glued up so that the bees were allowed to swarm as they thought best. They began swarming in April, and continued, they and their increase, until Aug. 15, at which time they had increased to 27. Seven of them went to the woods. This is no hear-say or exaggerated bee tale, but is a positive fact, and I would say (lest some one should think this a cheap advertisement), that the gentleman or myself either have no bees to sell, nor do we rear queens to sell, but we wish to keep our stock for rearing as near their present condition as possible. I have several colonies of blacks and hybrids that have not swarmed this year. Some I divided, but I prefer to let them swarm themselves, unless I had a good Italian

queen to give them. I found 4 colonies of bees in trees lately, one of which was yellow bees, and the most peaceable colony I ever handled, and the queen was the largest insect I ever saw in the shape of a honey bee. Almost all the trees I cut, were very rich in honey.

Mr. Heddon's answer to my 4th question in the BEE JOURNAL of May 23, is not exactly correct, for the bees had plenty of room inside, for some of the colonies were new swarms that had been hived but a few days; nor was it hot weather that caused the bees to lay out, for, on the contrary, it was moderately cool. Try again; I confess I cannot tell.

We have plenty of rain; wheat and oat harvest is almost over, and we are expecting a continued honey harvest, from the buckwheat, as well as the wild flowers, which are kept blooming by the bountiful seasons.

D. F. MARRS.

South Bosque, Texas, June 11, 1883.

Your queen went with your first swarm from No. 1 to No. 2. When colony No. 2 swarmed the first time, your old queen went into No 5, where she now is, if no mishap has occurred. My answer to your 4th question, which I have just re-read, is the best I can give, unless perhaps I were on the ground and looked more closely into details.

Why is This?

I have a first swarm of Italian bees with a fine 2-year-old queen, came off the middle of May; her young brood that she is hatching, is as black as any black bees I ever saw. They were as fine looking Italians, when I hived them, as I ever saw. I know it was a first swarm, for in 9 days I got a second swarm from the same hive. How do you account for it?

FRANK A. EATON.

Bluffton, Iowa.

By some "hook or crook," either in hiving or otherwise, your "2-year-old" Italian queen got displaced by a black one, and this black one can hardly be the daughter of the "2-year-old," or some "bands" would show upon her workers.

A Diseased Colony.

I have a colony of bees in my apiary that are suffering from some cause which I am unable to help. Young bees, unable to fly, crawl out of the hive and die; their bodies are distended and apparently filled with honey. My bees are working well on white clover, and have been for a week; still there is no change in this colony. What is the cause, and what the remedy? W. D. SIMONDS.

Augusta, Mich., June 12, 1883.

Having never had a case of the kind mentioned, from all I can imagine, by the symptoms given, I am unable to say what the trouble is. Were the case mine and I had confi-

dence that the trouble was more than temporary, which you seem to have. I would fall back to my favorite remedy, namely, destroy the queen and re-queen them from one of my very best colonies—best for qualities.

SELECTIONS FROM OUR LETTER BOX

Magnificent Honey Harvest.

We are in the midst of a magnificent honey harvest. Bees are just booming, and everybody who has bees are happy. ISAAC SHARP.

Waveland, Ind., June 20, 1883.

Bloom Late, but Welcome.

I do not complain of the weather. Providence controls that; if man controlled it, it probably would not be as good as it is. My bees, that I had packed in sawdust, came through all right, except one brown German colony, which was queenless. They were strong in bees, and I sent to South Carolina for a queen; she arrived on May 5; I introduced her on the 6th, and in 14 days, when I opened the hive, she had 7 combs filled with brood and eggs, and now the young Italians are flying, when the sun shines. Of my bees in my summer and winter house, those on the South side, came out strong; those on the North side are weak, and 2 colonies swarmed out. White clover is blooming in abundance; the fields and roadsides look white. It is late, but welcome. I. N. BECKER.

Oakfield Centre, June 14, 1883.

White Clover Never Better.

Bees have done well during the past two weeks; they are storing surplus honey very fast, and swarming still faster. Some of my neighbors, who work "on the old foggy plan," have a great deal of trouble with swarming. One man had four swarms from one colony in a month. The great trouble is, they wait until fall before putting on surplus arrangements, and as we have such an abundance of clover bloom, this season, the bees want room. The white clover crop was never better. EMIL NEREL.

High Hill, Mo., June 15, 1883.

Honey from Black Walnut Trees.

The prospect for a crop of honey in Lucas County, Iowa, is better than an average, at this season of the year. Bees never wintered better. I had drones flying on March 12, and had to give 12 colonies their upper story on April 27, to prevent swarming. I took off 200 pounds of buckeye and crab-apple honey. The bees never commenced killing the drones until June 1; and then but few. White clover is now plenty, and I have commenced to extract again. Everything that has bloomed this spring has furnished an abundance of nectar. I

never knew before that black walnut furnished honey; the bees worked on it equal to linden, and I extracted some 50 pounds of walnut honey; it is dark and strong, and hardly fit to eat; the bees left the clover for the walnut. We have had lots of rain and some cold spells, but that "silver lining" is seen, and we shall have another big honey crop in Iowa this year; it is so wet that the smartweed has possession of corn fields, and smartweed never fails. Last year I had to feed the bees until July 1; this year bees swarmed on May 1, and have kept it up ever since. I have 5 from 1, all natural swarms; the after swarms I divided, to save the young queens; 1 swarm had 3 queens. Linden promises well, and my bees are strong. We cannot help getting a big crop of honey, as soon as the linden blooms. White clover was never as good, but there was too much rain for clover. WM. MALONE.

Oakley, Iowa, June 18, 1883.

Average Crop of Clover Honey.

Since I wrote last, we had floods of rain; our honey crop is cut short; white clover is about done, but we have already secured better than an average crop of nice clover honey. I hope some of our Northern bee-keepers will exhibit honey, bees, and supplies, at the Louisville exposition. We have secured space, and will exhibit. It will be opened the first week in September. N. P. ALLEN.

Smith's Grove, Ky., June 21, 1883.

Bees Transferring Eggs.

The fact that bees sometimes move eggs for queen-cells has been thoroughly tested and positively proved in my apiary this spring. On the 23d of May I removed the queen and one frame of brood from a colony, and inserted a frame of foundation. On one side of the new frame was a nail which projected about an inch. On the head of this nail was built a large fine queen-cell which contained an egg. In a few days it was hatched and capped over. On the third examination it was, as all may know, much to my regret, accidentally bruised. Although I have believed for a long time that bees will sometimes move the eggs or larvae, yet I have never before seen it so plainly illustrated. T. A. HONGAS.

Henderson, Iowa, June 14, 1883.

Honey Harvest Prospect Never Better.

The prospect for a good honey crop in this vicinity, was never better. The cool weather about the 21st of May, did us no harm, though fires and thick clothing were not uncomfortable for two or three days. I commenced the season with 89 colonies; and during April and May I had 30 swarms. I look for a big swarming spree in a few days, as the hives are well-stocked with bees and brood, and I notice a few have queen-cells started. I have already taken 600 pounds of comb honey and 410 gallons of extracted, and will take out about 2 pounds (or 90 gallons) more next week. From the crossset colony of hybrids I ever

saw, I took, yesterday, 4½ gallons of extracted honey. The hybrids have given me more honey to the hive, than the pure Italians. As honey gatherers they far exceed the pure Italians; but they are crosser even than the blacks. I have a colony of blacks I would not exchange for the best Italians I ever saw; they are very gentle, and are good workers. Last season they gave me 184 pounds of fine comb honey, in one-pound sections, which I sold for 20 cents per pound, \$33.12. I use the Langstroth frame so far as length and depth goes; in the upper story, for extracting, I use 8 frames 1½ inches wide, which, after 5 years of trying other kinds and sizes, I find to give the best results. I extract often. CHAS. H. KINCADE.

Sterling, Ark., June 16, 1883.

Bee-Keeping in Utah.

Since I wrote you last Thos. W. Lee and myself have been down to Grantsville to organize a branch association of the Territorial Bee-Keepers' Association. Grantsville is situated on the west side of the Tooele Valley, and boasts of the first bee-keepers in the county, but for all that, Tooele city is a little ahead of them in bee-culture; for out of 17 bee-keepers, they have only one extractor; most of them getting comb honey without the section boxes. The swarming season is now in full blast, with myself it is about over. JOHN DUNN.

Tooele City, Utah, June 14, 1883.

Everything is Booming.

Our bees are firing their big guns. They wintered well. There never was such a fine prospect for white clover; bees are filling up the sections finely. Our rains are just right, and poplar is just blooming; linden will bloom this month, and soon after comes the sweet clover. Our honey crop is very good, and everything is booming. C. S. NEWSOM.

Athens, O., June 13, 1883.

Rain, Rain, Rain.

The bees in this part of the country are having a hard time, on account of the excessive rain. Hives are full of bees and brood, and a great deal of white clover is in bloom, but we have rain nearly every day, and streams are high most of the time. Our honey crop was an entire failure last year, owing to continuous rains during clover bloom, and our hopes of a honey crop, this season, grows less, day by day. Clover is the main dependence in our locality, and there is not an ounce stored in surplus boxes yet. W. J. DAVIS.

Youngsville, Pa., June 20, 1883.

Bees Strong in Numbers.

Bees in this neighborhood are doing finely, considering the cold wet spring we had. They are not storing any surplus honey yet, but are increasing in numbers amazingly. The hives are all crowded full of bees, and there has been several fine large natural swarms already. We expect a good harvest of honey. J. M. ROSS.

Tecumseh, Neb., June 15, 1883.

Well Done.

On page 300, Mr. J. O. Sherman gives a candid, clear report of what he has done by crossing bees, and what stock he used to do it with. Mr. S. is recognized by those who know him at all, to be a man of scientific turn of mind, as well as undoubted integrity. He did just what I have been doing for several years past, and any one who does thus, will become another witness to the living truth. May I be so impertinent as to ask Mr. F. I. Sage to give us the names of the Michigan bee-keepers whose honey he has handled, and the amount handled from each person named. Such statistics might throw much light on the separator question; at least, as far as Michigan producers are concerned. JAMES REDDON.

Dowagiac, Mich., June 15, 1883.

Profusion of Basswood Bloom Expected.

We have a few colonies that have stored 32 pounds of comb honey from apple blossoms. Bees are in fine condition. Alsike clover, white clover, and raspberries are in full bloom, but it is too rainy and cold. Basswood gives evidence of great profusion of bloom. Please tell us, through the BEE JOURNAL, if you have had any experience with the honey plant known by the name of *clathra unifolia* or white alder. I see it recommended by some bee-keepers, but would like your opinion of its merits.

A. W. OSBURN.

Water Valley, N. Y., June 18, 1883.

[Personally, we have not. It blossoms from July to September, when there are few other flowers. The honey from it is "about white, thick, and of fine flavor." It will grow in any soil, and is perfectly hardy; but it does best in a moist, rich loam. Several have reported, in the BEE JOURNAL, its excellent qualities for honey.—ED.]

Letter from Whitley County, Ind.

I am a beginner in the new method of bee-keeping (with movable frames), though having some experience in the old way with box hives. Last fall I purchased a colony of Italians of a neighbor in a Quinby hive. I kept them out during the winter, protected with chaff matting in the upper story and wrapped with strips of carpeting on the outside; they wintered splendidly, and came out all right this spring, casting a large swarm on the 15th, which was hived in a Quinby hive, and are doing well so far. We have a great abundance of white clover in bloom now, and the "little busy bee improves each shining hour, from early dawn to dewy eve," on its fragrant bloom. We have another plant here that I have not noticed anything mentioned by any correspondent of the BEE JOURNAL as a honey-producer; it is known here as ground ivy, the botanical name I do not know. It is a trailer, and grows from 7 to 10 inches high; blossoms about the middle of May, and con-

tinues for a long while in bloom; and, at the present writing, its vines are full of blue blossoms, on which the bees literally swarm from morning till night, almost forsaking all other blossoms; it grows spontaneously, and we farmers have considered it a great nuisance, on account of its tenacity of life, spreading through our meadows and yards, almost taking possession; but if it is a great honey plant, we, who keep bees, will be able to tolerate its presence on account of its honey secretions, if it possesses them. Please say if it is known to you as a valuable honey plant. We have also here in northern Indiana, a great amount of the linden and basswood, which bloom here about the middle of July. Our spring has been wet and cold, and bees have had a hard time, but the last few days have brought us warm, if not sultry weather, and now they are getting ready for business. A bee-keepers' convention or association has been formed in Whitley county, and its members meet once a month to discuss apianary subjects. Among its members who have given it much attention, I will mention the names of Levi Mosher, H. H. Lawrence, Wm. Kelsy, and Joseph Summers; the last named is, perhaps, the best posted, in reading and experience, of any man in the county; he has about 80 colonies of the Italian, and uses extensively the improved Quinby hive, and thinks it the best for all purposes; the only objection being the depth of the brood-chamber for convenient handling. W. H. W.

[Ground ivy has many excellent qualities. It will grow almost anywhere, and under the most adverse circumstances. It is a proverbial bloomer, and yields excellent honey in abundance.—ED.]

Heavy White Clover Bloom.

We are having a heavy crop of white clover, but bees have had but little good of it yet. Out of the last 78 days it has rained, more or less, 41 days; some days all day, and all night too. I have had no swarms yet, out of 79 colonies. By feeding, I have kept my bees in good condition, and hope to have some honey yet.

S. L. VAIL.

Coal Creek, Iowa, June 19, 1883.

The Season in Scotland.

The weather has been very severe all winter, and the spring has been exceedingly cold and bitter, so that our bees, throughout the whole country, are in a very backward state. As far as the season has gone there is no great prospect of us having a good harvest. We are busy preparing for our annual show, which takes place at the end of July, in Inverness, in the North of Scotland, a good distance past "Perth." I will send you one or two schedules, and will be very glad if you or any friends could send any exhibits to it.

JOHN D. HUTCHINSON.

Glasgow, Scotland, May 31, 1883.

Bee-Culture in Nebraska.

Bee-culture is fast becoming one of the leading industries in this State, and all we need is correct knowledge to make a grand success of it, having all the other requisites all ready furnished by nature. JOHN HAMMITT.

Wahoo, Neb., June 15, 1883.

Rearing Pure Queens.

I have 4 colonies of hybrid bees (a cross between the black and Italian) in moveable frame hives, into one of which I introduced an Italian queen about a month ago, and the young Italians are now beginning to be seen at work. I should like to Italianize the other 3 colonies, but do not know how to go about it, owing to the fact that black drones are found in all 4 hives. Will you please inform me in the Weekly JOURNAL, when and how I can manage so as to rear queens and have them fertilized by Italian drones, and greatly oblige? J. F. C.

New Orleans, La., June 16, 1883.

[It cannot be done with any degree of certainty. The only way will be to obtain fertilized queens.—ED.]

Work I Have Accomplished Alone.

As all the reports I see published are rather discouraging, as regards the honey crop, I will give my report for this season, so far. My bees started off well in the spring, and carried in the first pollen on Jan. 28. I had my first swarms on March 2. Linden commenced to bloom on May 15; then wild China and horsemint; and now elder is blooming. I commenced extracting on June 4. I have now extracted 5,500 pounds, and have 1,000 pounds of honey in one-pound sections, and I did all the work myself, except the winding up of my buckets and drawing the honey from a large tank into small vessels, which my better-half did for me. I started with 125 colonies; and extracting and attending to the swarms, kept me stepping about pretty lively. I have reports from all the principal parts of our State, and nearly all are feeding their bees. My honey is pronounced by all as equal to white clover honey, and weighs a little over 12 pounds to the gallon. J. W. ECKMAN.

Richmond, Texas, June 18, 1883.

Too Much Wet Weather.

Bees are doing splendidly this spring, considering the kind of weather we have had. White clover has been in bloom since the latter part of May, and the fields are white with it, but the bees do not get more than three days in a week in which they can work. When it is not raining, it is so cloudy and cold that the bees cannot get out; they have not been out now for three days. I extracted about 75 pounds of honey, and have some of them working in sections. Last year I got no surplus before Aug. 1; that is our regular time for surplus. I could not consent to do without the BEE JOURNAL, or miss one number. RICHARD GUNSELL.

Baden, Mo., June 18, 1883.

Fuel for Smokers.

Some writer in the AMERICAN BEE JOURNAL once said he had found out a good use for old almanacs, by saturating the leaves in a strong solution of salt-peter, then dry and use with cotton rags in the smokers. I have always been troubled about fuel for smokers till I tried this. Take two pieces of print paper, about the size of almanac leaves, prepared as above, which should be rolled with the cotton rags and ignited and put in the smoker. This will make a good, enduring and constant smoke. The salt-peter is a good disinfectant, and is a positive benefit through its use. Try it, brother bee-keepers, and report.

D. HIGBEE.
 #Avoca, Iowa, June 16, 1883.

How Bees Wintered in Wisconsin.

I have traveled over four towns, and have made a careful inquiry of every bee-keeper I have met, and I am now satisfied that the losses during the last six months amount to not less than one-third, nor more than one-half of all the bees in this county. The losses are about equal to the losses of two years ago. As to the causes, it is very difficult to determine exactly. A long, cold winter, followed by a cold spring, is the first thought; but that some have wintered their bees without loss while others have lost all, proves that there are other causes than the cold. I have lost more bees during the past winter, than in all my life before, and I have kept bees for ten years. I have lost 50 out of 120 colonies. I left 5 colonies out; 3 well packed in chaff hives, and 2 with no protection. All died. The balance were stored in three cellars. Cellar No. 1 was very cold; everything froze solid; and three-fourths of the bees died. Cellar No. 2, under my house, was dry; temperature from 34° to 40°; generally about 36°. Bees suffered badly, but were much better than in No. 1. In both these cellars, both upward and downward ventilation was given freely. Of 90 colonies put in these two cellars, I have 48 left. Cellar No. 3, under another house, contained 26 colonies; 22 of them are alive; 20 of them are strong and about to commence swarming. These were given little or no upward ventilation. Were put in the cellar before freezing. I shall ventilate my cellars to keep the air purer, and make them a little warmer the next cold winter, and, if possible, use ice to keep the temperature down during a winter thaw.

F. WILCOX.
 Mauston, Wis., June 18, 1883.

Piling in the Honey.

I have 90 colonies doing well, and piling in the honey; I find the BEE JOURNAL of great benefit in their management.

J. MCCONNELL.
 Clay Village, Ky., June 14, 1883.

Fine Flow of Honey.

We are having a fine flow of honey now in this part of our State from white clover. DR. J. COOPERIDER.
 Taylorsville, Ind., June 18, 1883.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Do not send coins in a letter. It is dangerous and increases the postage unnecessarily. Always send postage stamps, for fractions of a dollar, and, if you can get them—one-cent stamps; if not, any denomination of postage stamps will do.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Special Notice.—We will, hereafter, supply the Weekly BEE JOURNAL for one year, and the seventh edition of Prof. Cook's Manual of the Apiary, bound in fine cloth, for \$2.75, or the Monthly Bee Journal, and the Manual in cloth for \$1.75. As this offer will soon be withdrawn, those who desire it should send for the book *at once*.

Sample Copies of the AMERICAN BEE JOURNAL will be sent *free* to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Bingham Smoker Corner.

Large Smokers need wide shields. Bingham's have them, and springs that do not rust and break, and bellows that sparks and smoke do not enter. The Conqueror has all improvements made to date, and a 3x7 inch stove, and 5x7 inch bellows. Sent post-paid for \$1.75. Address.

BINGHAM & HETHERINGTON,
Aubonia Mich.

All Excelling. — Messrs. Bingham & Hetherington. Dear Sirs:—I am now selling your Smokers almost exclusively. You are excelling yourselves in smokers all the time.

Respectfully, J. G. TAYLOR.
Austin, Texas, May 10, 1883.

Cyprians Conquered.

All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am "boss." Bingham's "Conqueror Smoker" did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham.

G. M. DOOLITTLE.
Borodino, N. Y., Aug. 15, 1882.

During the following three months, Bingham Smokers will be sent post-paid, per mail, on receipt of the following prices:

The "Doctor" (wide shield)—3½ in. fire tube, \$2.00
The Conqueror (wide shield)—3 in. fire tube, 1.75
Large (wide shield)—2½ in. fire tube, 1.50
Extra (wide shield)—2 in. fire tube, 1.25
Plain (nar. shield)—2 in. fire tube, 1.00
Little Wonder (nar. shield)—1½ in. fire tube, .75
Bingham & Hetherington Unpacking Knife..... 1.15

With thanks for letters of encouragement, and the absence of complaining ones, we tender to our thirty-five thousand patrons our best wishes.
Very Respectfully Yours,

BINGHAM & HETHERINGTON,
Aubonia, Mich., June 1, 1883.

We have received a photographic view of "Rose Hill Apiary," Belleville, Ill., "with the compliments of E. T. Flanagan, proprietor." It presents a nice view, and hangs on our office wall.

Do not let your numbers of the BEE JOURNAL for 1882 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

May we ask you, dear reader, to speak a good word for the BEE JOURNAL to neighbors who keep bees, and send on at least one new subscription with your own? Our premium, "Bees and Honey," in cloth, for one new subscriber to the Weekly, or two for the Monthly, besides your own subscription to either edition, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

The Central Kansas Bee-Keepers' Association will meet at Manhattan, Kansas, on June 30, 1883.
THOS. BASSLER, Sec.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Articles for publication must be written on a separate piece of paper from items of business.

HENRY ALLEY, WENHAM, MASS.

BEES and HONEY,

OR THE

Management of an Apiary for Pleasure
and Profit; by

THOMAS C. NEWMAN.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most money in its best and most attractive condition.

Appreciative Notices.

A neat and abundantly illustrated hand-book of apiculture.—American Agriculturist, N. Y.
Its chapter on marketing honey is worth many times its cost.—Citizen, Pulaski, Tenn.

Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of every beginner with bees.—News, Keithsburg, Ill.

Valuable for all who are interested in the care and management of bees.—Dem., Allegan, Mich.

Engravings are fine. Gotten up in the best style, and is cheap at the price.—Farmer, Cleveland, O.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—Farmer, Lancaster, Pa.

PRICE—Bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

THOMAS C. NEWMAN,

925 W. Madison St., Chicago, Ill.

ELECTROTYPES

Of Engravings used in the Bee Journal for sale at 25 cents per square inch—no single cut sold for less than 50c. **THOMAS C. NEWMAN,**
925 West Madison Street, Chicago, Ill.

THIS PAPER may be found on file at Geo. P. Rowell & Co.'s Newspaper Advertising Bureau (10 Spruce St.), where advertising contracts may be made for it in NEW YORK.

THE AMERICAN
BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

What to do with the Honey.

The honey crop, this year, will be simply *immense*. Mr. F. L. Dougherty, in the *Indiana Farmer*, says: "From daylight to dark, yes, away after dark, too, honey is coming at a fearful rate." And this state of things is corroborated by hundreds of letters from all over the American Continent. Not only is this so in America, but we hear that it is also true of England. The *British Bee Journal* for June 15, says: "A month's uninterrupted fine weather has amply repaid those who were careful to get there stocks in order for the first honey *glut*, which, from reports that have come to us, has been a very heavy one. We hear of the extractor being at work and supers being filled with marvelous rapidity."

As the crop will be an exceedingly large one—the question at the head of this article is very pertinent. The markets of the large cities will be glutted—and, unless bee-keepers come to the rescue, by creating a home market, the prices will be run down very low, and sales, at the same time, will be exceedingly slow.

Every bee-keeper must take the matter in hand, and create a home market for his honey, by putting it up in attractive shape, both comb and extracted, to entice the lovers of pure sweets, making many more consumers. By the aid of small packages of comb honey, in one and two-pound sections, and small pails of extracted honey, containing from 1 to 10 pounds, an immense amount can be sold in every town on the American Conti-

nent, if the right methods are employed for creating a market.

We know of no better plan than to spread information on the uses for honey, its healthfulness and medicinal qualities, among the people in every town adjacent to your apiary.

We have given this matter much serious thought, and have concluded, in order to assist honey consumption, in the present emergency, to revise and condense our pamphlet on "Honey, as Food and Medicine" to 16 pages, so that it may be scattered like autumn leaves throughout the length and breadth of the country at a *small cost* to bee-keepers, and thus **CREATE** a market for our honey. Twenty thousand copies have already been sold, and we will have another edition of 10,000 copies printed by the time this paper is in the hands of its patrons, ready for immediate work. They will be printed in English and German, and may be had in either language as may be desired, or some of the German may be put in an order for 100 or more, if requested. On the first page we will print a card, *free of cost* (when 100 or more are ordered), something like this:

PRESENTED BY JOHN SHORT,
Swanecetown, Ga.

Producer of Comb and Extracted Honey.

Orders by Postal Card promptly filled.

These pamphlets will retail at 5 cents each, or 50 cents per dozen. 100 copies (with Card printed free of cost) 3 cents each; 500 copies at 2½ cents each, or 1,000 copies at 2 cents each by mail postpaid. If these pamphlets are properly distributed, they will become salesmen through whose influence every pound of honey that is produced, will find a ready and remunerative sale, and will prevent a *honey glut* in our large cities, as well as make both producer and consumer happy. Hundreds of bee men have already tried this plan, and found it to "work like a charm." If twenty

thousand of these silent "salesmen" have already wrought wonders in creating a market for honey, what will a million of such faithful "workers" accomplish in the "hive of nature?" Just try it, and astonish yourselves with the results!

The Rev. L. L. Langstroth.

Again, after a lapse of nearly two years, we have received the following note from the greatest American bee-master, the Rev. L. L. Langstroth:

The Weekly BEE JOURNAL is regularly received, and abounds in matter both interesting and valuable to every bee-keeper. After being laid aside from the use of my pen for almost two years, I am able again to take interest in bee matters, and hope to send you an article shortly. I am trying to induce a neighbor to send you a correspondence between himself and one of the glucose manufacturers. He wrote for terms of grape sugar for feeding bees this last spring, and the glucose was sent instead, as a good thing to mix with honey! With sincere thanks for your many acts of kindness, I remain, as ever, very truly your friend, L. L. LANGSTROTH.
Oxford, Ohio, June 28, 1883.

The whole apicultural world will be glad to learn that this veteran is again able to use his pen, and will read his articles with the greatest avidity. We do not think he intended his private note to us, for the public eye, but knowing how great is the desire still to hear from our common friend, we take the liberty of publishing it. If strength of mind and body are still retained, our readers will doubtless hear from him as opportunities may present themselves.

New Music.—We have received two new pieces of music from the author, Mr. W. Chitty, St. John's School, Pewsey, Wilts, England. They are new and popular Marches, and very pretty. Mr. Chitty is one of our English subscribers, and is very enthusiastic on bee matters. He will send these Marches, to any address for 25 cents each.

Honey and Bee Shows.

The season for these shows is approaching, and, as they do more in educating the people concerning the uses of honey and its consumption than almost anything else, we hope that bee-keepers throughout the country will take special interest in them, and make an exhibit at every Fair open to them, which will be alike creditable to them and the Fairs whose managers show a desire to foster the honey exhibits.

Last fall, Mr. C. H. Lake made an exhibit at the Virginia State Fair that was the great attraction, and aided much

which was sent to this office by Mr. Lake last fall, and is now in our office album. The first person shown on the right is Mr. Lake, the manager of the apiary, the others being some friend and assistants.

In this tent he had a large display of bees and hives, as well as a quantity of honey, both comb and extracted. A correspondent remarks as follows concerning this exhibit: "He took the premium on a lot of button-bush honey that was the whitest I ever saw. He also showed the three races of bees, and one imported Italian queen that breeds bees with the white bands like the so-called albinos;

append two extracts from the Richmond dailies of last November. They are as follows:

The exhibit of the Sunny Side Apiary, of Baltimore, deserves more than what the newspapers have said about it. Mr. C. H. Lake is the manager, and was very busy yesterday showing the workings of his new hives, which are considered by bee-keepers to be the best made. Mr. Lake exhibited Cyprian, Holy Land or Syrian, and the two species of Italian bees. From one colony 220 pounds of honey was obtained in six weeks.—*Daily Whig*.

One of the attractions at the Fair is the exhibition of Mr. Charles H. Lake, manager of the Sunny Side Apiary at Baltimore, Md. This gen-

BEE TENT OF C. H. LAKE'S APIARIAN EXHIBIT AT BALTIMORE, MD.

in bringing honey and bees to the public notice. Concerning this exhibit the following from the secretary of the Fair will speak for itself:

I cannot avoid thanking you for the extremely interesting exhibit you made of bees and everything relating thereto, which I believe has done more to excite interest in and to cause an appreciation of that department of produce and industry among our people, than all presentations and exhibitions heretofore made at our fairs.

GEO. W. MAYO, Sec.,
Virginia State Agricultural Society.

This bee tent is shown by the engraving on this page, a photograph of

so it showed that the albinos are not an American race."

Mr. W. A. Hammond and Mr. J. W. Porter also exhibited honey and bees. It was generally admitted that the interest shown in the apiarian exhibits was very great, and that the exhibits themselves were far ahead of any that had ever before been made there.

This shows what can be done at every Fair in the country if the bee-keepers will make the necessary exhibits.

In order to show how the daily papers view these exhibits, we will

leman has a large tent, under which he shows a case of over two hundred pounds of honey made from one hive; has several colonies of Italian bees, one of Cyprian bees, and also other foreign bees. Every appliance used in this business is shown by Mr. Lake. He is running seven hundred hives this season.—*Daily Dispatch*.

While on this subject we would incidentally remark that a matter of much importance, is the making out of a good Prize List, to attract exhibitors. The smallness of such have heretofore been a great hindrance to apiculture. We are pleased to see a very marked improvement in this

matter of late, and have no doubt but these evils will, in time, correct themselves, especially if bee men will call the attention of the Fair managers to the matter.

The exhibition to be held at Toronto, Ontario, from Sept. 11 to 23, 1883, will be an important one for Canadian bee-keepers, and the directors have issued the following Prize List for Honey and Apian Supplies, open to all bee-keepers:

	1st.	2nd.	3d.
Largest and best display of extracted honey	\$10	\$5	\$3
Largest and best display comb honey	10	5	3
Largest and best assortment of different kinds of extracted honey, not less than 2 lbs. of each variety	5	3	2
Best assortment of comb honey in sections, not less than 20 lbs.	3	2	1
Best style and shape of section, or sections of comb honey	3	2	—
Best beeswax, not less than 10 lbs.	3	2	—
Best mode of marketing extracted honey	3	2	—
Best mode of marketing comb honey	4	2	—
Best comb foundation for brood chamber	3	2	—
Best comb foundation for section or honey boxes	3	2	—
Best and most secure mode of wintering out-doors in any kind of hive	3	2	—
Best house for wintering bees, and of most use for apian purposes in summer—working model to be on ground, represented by a scale of not less than one inch to the foot	3	2	—
Best mode of securing the largest yield of box honey from a single hive	3	2	—
Best mode of securing the largest yield of extracted honey from a single hive	3	2	—
Best form of Hive	3	2	—
Best winter and summer hive	3	2	—
Best stand to place under hives for ordinary use	3	1	—
Best wax extractor	3	1	—
Best honey extractor for general use	3	2	—
Best style of comb-basket for extracting from pieces of comb	2	1	—
Best arrangements for uncapping	2	1	—
Best box smoker	2	1	—
Best honey knife	2	1	—
Best bee tents	2	1	—
Best bee veil	2	1	—
Best hat where the veil is not used	2	1	—
Best queen nursery	3	1	—
Best labels for extracted honey	3	2	—
Best labels for comb honey	3	2	—
Best style and assortment of tin for holding extracted honey	Bronze Md'l		
Best section frame for body of hive	2	1	—
Best section crate for top story and system of manipulating	2	1	—
Best system of manipulating section in section frame	3	1	—
Best machinery for raising frames	3	1	—
Best exhibit of curiosities	3	1	—
Best collection of honey plants	3	2	—
Best system of transferring, illustrated	3	2	—
Best and largest display of apian supplies	10	5	—
Best and most practical and new invention for the apianist	3	2	—
Best exhibit of bees and new races of bees	5	3	—

Open only to Bee-Keepers who have not had over 25 colonies during the season of 1883.

	1st.	2nd.	3d.
Best 10 lbs. of clover honey (extracted)	\$2	\$1	\$50
Best 10 pounds of basswood honey (extracted)	2	1	50
Best 10 lbs. of Canadian thistle honey (extracted)	2	1	50
Best 10 lbs. of golden rod honey (extracted)	2	1	50
Best 10 pounds of bone of honey (extracted)	2	1	50
Best 10 lbs. of Aster Honey (extracted)	2	1	50
Best 10 lbs. of any other fall flower honey (extracted)	2	1	50
Best 10 lbs. of comb honey in sections	2	1	50

The Canadian *Farmer* remarks as follows concerning the National Convention to be held there at the same time: "The Annual Convention of the Bee-Keepers' Association of America, will be held at Toronto during the second week of this Exhibition, at which bee-keepers from all parts of Canada and the United States will be present. This show and the

convention, with the lectures to be delivered in connection therewith, will be of special interest to all engaged in this now important industry." Those who can, should make arrangements to attend both the Convention and Bee and Honey Show.

LATER.—Just as the JOURNAL is ready for the press, we have received a few lines from President D. A. Jones saying that the Convention will be held on Sept. 18, 19 and 20, 1883, at Toronto. Further particulars hereafter.

The Glenwood Apiary.—We have received from Mr. W. H. Shirley a nice view of his apiary at Glenwood, Mich., and have placed it in our office album. Mr. Shirley describes it as follows:

By this mail I send you a small picture of your humble servant, and part of my apiary, as it looked, June 16, 1883. The small building in the centre of the apiary is a house fixed to take colonies in, to handle, in time of robbing. I also use it for taking off honey in the fall (getting the bees out of it). The larger building shown is the house apiary Mr. Heddon built and kept bees in two years, I believe. I use it as a work shop, supply room, etc. The picture shows about four-fifths of my bees. Perhaps you will think it worthy of a place in your museum. White clover is yielding first rate here now. W. H. S.

Care of Comb Honey.—Relative to this important matter, the Indiana *Farmer* gives these timely hints:

If you have not got the time to sort out the sections and brush off the bees, set the sections or boxes in a clean barrel or box, and spread a white cloth over the top. The bees will leave the honey and crawl up to the cloth. Turn it over at intervals and let the bees out. Keep the honey removed in a warm place, and keep a lookout for worms. If the honey shows signs of being worked, fumigate the infected sections with sulphur. Too much will turn the combs green.

"The Poulterer's Guide, for treating diseases of poultry, with symptoms and remedies for their treatment," is the title of a new pamphlet of 24 pages, by C. J. Ward, editor of the *Poultry Journal*, Chicago, Ill. This is very valuable for those who keep poultry, and the small price at which it is published (15 cents), as well as the name of its author, will cause it to have a large sale. It covers all the diseases in poultry, and prescribes reliable remedies. We can furnish it to those who may desire it.

A Swarm of Bees.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
Monday, 10 a. m., July 2, 1883. }

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY.—The nominal price of extracted is 7c. for dark and 9c. for light here. The supply is abundant and sales are slow.

BEESWAX.—None in the market.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY.—The market for extracted honey is lively, and the demand exceeds the arrivals. Our stock is small and we are in danger of having sold out every day. We pay 7c. for good honey on arrival, the latter price for choice clover. There is a small demand for comb honey, and prices nominal.

BEESWAX.—Arrivals of beeswax are plentiful. We pay 35c. for a good article on arrival.

CHAS. F. MUTH.

Quotations of Commission Merchants.

NEW YORK.

HONEY.—Best clover in 1-lb. sections (no glass) 22c. 23c.; in 2-lb. sections (glassed) 18c. 20c. Fair quality, 1 and 2-lb. sections, 17c. 18c. Extracted, white, in small barrels, 16c. 17c.; buckwheat, 8c. 9c.

BEESWAX.—Is more plentiful. Prime yellow sells at 37c. 38c.

H. K. & F. R. THURBER & CO.

CHICAGO.

HONEY.—The demand for extracted is good, and the market bare of all unfurnished honey. Prices range from 8c. to 10c. Comb remains lifeless and will until the new crop comes, or until August. Sales of comb are being made at 8c. to 15c.

BEESWAX.—35c. 36c.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY.—Nearly 300 cases new, mostly extracted, arrived per Southern steamer on Monday, June 15. Sales of part of the same in a wholesale way were made at 6c. Retail transfers were made at a little higher figure. Quotations for comb are nominal. There is a little choice new comb offering, but no sales reported. One buyer offered 12c. for six cases, but insisted on being allowed about 3 lbs. extra tare. White comb, new crop, 12c. 15c. Extracted, choice new, 6c. 7c.

BEESWAX.—Wholesale, 27c. 28c.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY.—Very little call. Occasionally barrels of strained and extracted sold at 6c. to 7c., but nothing worthy of mention done in comb. New quotable at 14c. and old nominally less.

BEESWAX.—Easter, at 35c. 36c.—one lot sold at 33c. W. T. ANDERSON & CO., 104 N. 3d Street.

CLEVELAND.

HONEY.—There is a moderate sale for best white 1-lb. sections at 18c. occasionally 19c. but 2 lbs. are not called for. Extracted has no sale at all.

BEESWAX.—Not offering.

A. C. KENDEL, 145 Ontario Street.

BOSTON.

HONEY.—Our market is fairly active. We quote: 1-lb. sections at 30c.; 1-lb. sections, 22c. 23c.; 2-lb. sections, 20c. 22c. Extracted, 10c. per lb. Good lots of extracted are wanted in kegs or barrels.

BEESWAX.—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatham Street.

CORRESPONDENCE

For the American Bee Journal.

Drones with First Swarms.

G. M. DOOLITTLE.

As spring arrives, and the hive becomes populous with bees, their instinct leads them to obey the divine command, "to multiply and replenish the earth." To this end they commence preparations for swarming, the first of which is the depositing of drone eggs in the drone cells by the queen.

Soon after this, the embryo queen cells are started, and if the secretion of nectar is good, the queen deposits eggs in these as soon as the population is sufficiently increased to warrant a division of their numbers. The eggs are not usually deposited in the queen-cells till the drones are hatched quite plentifully. When the time comes for swarming, which is as a rule when the first queen cell is capped, the bees rush out *en masse*, including the old queen, and one-eighth or more of the drones. Many seem to suppose that no drones go with the first swarm having the old queen, claiming it is unnecessary, and for this reason it is said that "the drones remain in the hive to fertilize the young queens."

As there is plenty of drones hatching at this time, there is no need of all of them remaining, which are hatched, as it will still be seven days before the first young queen leaves her cell, and then from 5 to 8 days before she takes her "wedding flight," making 12 to 15 days, during which time one-half of the drones which were in the cells at the time the swarm issued will have hatched. I am well aware that a far greater number of drones go with a swarm having an unfertile queen than with a swarm having an old fertile one, for a greater necessity for them exists; still, the old queen is always liable to accident, which might occur soon after a few eggs were deposited in the worker cells, being built by the bees; in such a case they could rear a queen, but no drones; hence, if none went with them, their young queen would prove of no value. Nature is very provident in all her ways, and the instinct of the bees leads them to prepare for any case of emergency.

We would conclude that where there were plenty of drones in neighboring hives, that there was no need of every swarm having drones, but the bee uses no reason, and thus rears as many drones in a yard containing 500 hives, as if the hives were isolated 100 miles from any other. I have had two swarms this season, and, although, few drones have been reared this year on account of cold and wet weather, still each swarm contained a score or more of drones.

Borodino, N. Y.

Prairie Farmer.

Apiary Talks—Hoarded Honey.

MRS. L. HARRISON.

Millions of heads of white clover and millions of drops of rain. A large amount of honey has been secreted and stored during the few hours of sunshine intervening between showers. Hives are overflowing with bees, honey and brood; just the exact condition for storing surplus, should the weather be favorable. The wet weather will prolong the bloom, if it does have to "waste its sweetness on the desert air," and insure good fall pasturage. Whenever the sun shines out hot, a vigilant eye should be kept on the apiary, lest the bees swarm and decamp for the woods. Bees mean business when they swarm, and will not wait for hives to be made, or to go to town and buy.

Old hives that are to be used should be thoroughly cleansed, and free from offensive odors. Bees become very warm during the excitement of swarming, and if put into a close hot hive, and left in the sun, will invariably seek more comfortable quarters. We once had a very large colony desert the hive the day after swarming, and leave for the woods, because the sun was shining very hot upon them, and they were crowded, we having neglected to put on surplus boxes. As a rule, with few if any exceptions, bees cluster before leaving. If they have issued and returned to the same hive again several times, they may take a final departure without clustering; or if they dislike their hive they will take wing and leave. Bees that have been clustered for days, on the outside of their hives, are more apt to leave than others. They should be kept at work, and not allowed to lie idle and study up mischief. Plenty of room should be provided inside of the hive for them to cluster in, and if a sudden flow of honey occurs, it will be improved.

Our surplus boxes are made by fastening seven "prize boxes" together with little strips of wood, and glazing the ends. Three of these cover an eight-frame Langstroth hive. In removing some filled boxes from the hive lately, the thought occurred to me to try the late Adam Grimm's plan of getting the bees out. We have a little hive in which we have an imported queen. It has two frames about 4 inches square. We put a newly hatched queen into it, and set it into a large box, and then placed the honey boxes alongside of it, and covered it up to prevent robbing. The old bees returned to their hive through a knot-hole in the box, and the young ones crawled into the small hive with the young queen. When the bees were all out of the surplus boxes the little hive was full of young bees, and were a regular organized colony, and put on airs like one. In this way no young bees were lost, as is sometimes the case.

When a swarm issues it goes forth with haversacks loaded, carrying three days' rations. If from any cause the honey flow is interrupted, either by

long continued wet weather or drouth, the colony must perish, as it has no old stores to resort to in an emergency. Bees, as a rule, or with a few exceptions, never desert uncapped brood, and many apiarists practice giving all new swarms a frame, so that they will remain. If, from any mishap, they lose their queen, they have the means at hand to raise another. This frame also contains honey, which is some help to the bee family just commencing housekeeping. If a frame of honey is also given them, their preservation will be insured.

Peoria, Ill.

For the American Bee Journal.

Cost of Changing Frames and Hives.

W. H. STEWART.

Several writers for the BEE JOURNAL seem intent on having bee-keepers, throughout the land, all adopt the same comb frame. This means the use of the same hive. The use of the same frame and hive means throwing away all other hives and frames now in use, and the destruction of many nice combs, except the one kind that is to be adopted. Every sensible bee-keeper knows that such a move, if carried out, would result in the sacrifice of at least one-half of all the property now invested in the bee business.

Not only the discarded hives, frames and combs would be lost, but extractors made for the use of the American or the Gallup frame would be of no use for the Langstroth, and that made for the Langstroth would be of no use for the others. All the wide frames for holding sections on the American and Gallup, also those made to use crosswise of the Langstroth, above and below, would become kindling-wood if none but the long Langstroth is to be adopted.

To me it would appear just as reasonable to require that all bee-keepers should look alike in the face, weigh the same number of pounds and ounces, wear the same size of boots, and to have the same climate and other surroundings, as to require that all should adopt the same hive, frame and extractor. It is a well-known fact that men differ just as widely in opinion as in appearance, size and shape.

Natural law so dictates that men ever have, and ever will, not only differ in opinion as much as in appearance, but that men as nearly alike mentally and physically as they could possibly be matched, if placed in different climates and having different surroundings, would behave widely different. Men are creatures of habit and influence. Men that have become accustomed to chop with a single-bladed ax are slow to learn to use one with a double bit. Men that have learned to use the right-handed plow would feel very awkward in attempting to use one that turned the land in the opposite direction. Men that have practiced the use of the American frame and hive, would have to learn many new motions and maneuvers

to become experts with the Langstroth or Quinby frame.

Again, those that have learned to give their bees the best advantages in both summer and winter with one shaped hive, would have to experiment for years before they would be able to do the same with another hive and frame, differing so widely as do the Gallup and Quinby.

And yet again, men are seldom willing to sacrifice all the stock that they have carefully invested in a business. Even if an economical bee-keeper should become satisfied that he could do somewhat better with a different hive if he has a hundred or more colonies in hives that work reasonably well, he will not hurry himself to make an entire change. Another objection to this proposed constitutional amendment is, that many bee-keepers choose to winter part or all their bees on the summer stands; and in this locality that way of wintering, and the use of the Langstroth hive and frame, would mean the loss of the bees. Even the chaff hive, with the Langstroth frame is a failure as an out-door winter hive in this part of the Northwest.

And yet again, many experienced, careful and thorough bee-keepers find practical advantages in the use of one form of frame and hive that they fail to find in the use of any other, and they would not consent to forego those advantages on any consideration.

Please let me ask those who are advocating the adoption of the Langstroth frame as the standard, suppose it were put to vote, as to what frame we should all adopt, and a majority should cast their vote for the American frame, would you forego your choice, discard the Langstroth and adopt the American? Tell us, please, how you feel about that part of the universal suffrage business.

Orion, Wis.

Haldimand, Ont., Convention.

The Haldimand Bee-Keepers' Association met at Cheapside on June 16, pursuant to adjournment. Members present: E. DeCew, President; Messrs. Jas. Armstrong, Robt. Buckley, William Jack, William Kindree, Andrew Vanderburg, A. Gloyd, Henry Smith, F. Mehlenbacher, E. Gee, D. Byers, Mansel McCollom, Wm. Harrison, R. W. Beam, Robt. Anguish, D. Rose, Dr. Harrison, Jas. Caldwell, and E. C. Campbell.

The minutes of previous meeting were read and adopted.

The first questions discussed were: "How to successfully winter bees, and to prevent spring dwindling." The president gave his experience; he had 15 colonies in the winter, and had lost them all. He attributed his loss to two causes—extracting too late, and not feeding enough back, and spring dwindling. He packed his bees in straw.

Mr. Smith packed his bees in chaff, and did not lose any.

Mr. Jack fed some of his colonies in the fall, and packed them in dry sawdust, and brought them through

all right. Those not packed died during the winter.

Mr. Armstrong thought that with proper protection, plenty of stores, and young bees, there would be little or no loss in winter. He packed his bees in sawdust, and left them in the packing until about the 10th of May, and lost only 4, one of which was queenless.

Mr. Vanderburg wintered his bees in double-walled hives, well packed, and gave them plenty of stores so as to keep up late breeding, and brought them through successfully. He did not lose any.

Mr. Buckley thought the great secret of wintering successfully was in having plenty of young bees. He put 38 colonies in the cellar in the fall, took out 33 in the spring, had lost all but 8 in April and May, by spring dwindling.

The secretary gave his plan of wintering, and an account of a visit to the apiaries of D. A. Jones, of Beeton, his method of wintering, and how to prevent spring dwindling. Mr. Jones uses a bee-house with walls two feet thick, packed with sawdust and ventilated by pipes running under ground. His plan of preventing spring dwindling is to leave the bees in the bee-house until there was plenty of pollen for the bees to work on, and closing the hives on cold or windy days after being set out.

Messrs. Gloyd, Kindree, Byers and Beam gave their views, mainly the same as given by others.

Dr. Harrison gave an amusing account of his first attempt at wintering bees. He bought 2 colonies at Holterman's sale late in October, and when he and Mrs. Harrison examined them, a few days afterwards, found that they had not half a pound of honey between them. He carried them into the house, put them into an empty room, darkened the windows, and fed them, all winter, with a thin syrup, by means of an inverted fruit jar. On warm days, he opened the window so that they could have a fly, and they came through all right, and he has them yet.

Mr. Rose, an old bee-keeper, gave his experience in wintering bees in different ways, and succeeded best with the old box hive.

Which are the best race of bees? Mr. Kindree thought hybrids were better honey gatherers than either blacks or Italians.

Mr. Buckley thought there was as much difference between Italians and blacks as there is between thoroughbred and grade cattle. The Italians were far ahead of the blacks, and gave instances in proof of his view.

Mr. Armstrong also liked the Italians, and thought they were superior in many respects.

Mr. Rose liked the Italians because they were so gentle and easy to handle, but did not know whether they were better workers or not.

The secretary spoke in favor of the Holy Land bees, saying they were splendid workers, and not half so cross as they got credit for.

The following resolutions were passed:

Resolved, That application be made to the various agricultural societies for space and prizes on honey and apiarian supplies, at the fall shows.

Resolved, That the next meeting of the Association be held on Saturday, 22d of September, at Cayuga, at 1 o'clock.

E. C. CAMPBELL, Sec.

Frankford Herald.

Preparing for Emergencies.

JOHN SHALLCROSS.

The young bee-keeper has, no doubt, learned by this time that there is a wide difference between theory and practice. That while the one is important and instructive, the other is full of value, as a means to success. An occasional mishap keeps the beginner upon the alert, and teaches him to make the best use of his resources.

He has expected abundant stores in his section boxes, while the bees have insisted upon filling the brood combs. He has tried to Italianize his colonies, but his most expensive queens have been rejected and destroyed. He has intended to prevent natural swarming, but the perverse insects have taken wing in spite of him. Other disappointments hedge up his way until, in his discouragement, he concludes that bee-keeping is not all romance. It is a wise and wholesome instructor. It is to the amateur the beginning of wisdom. It sets him thinking. He begins to ask questions, and to read up on the subjects of his failure. He realizes the cause of his mistakes, and learns how to prevent a recurrence of them. He begins to believe he is traveling a safer path, and knowledge comes in proportion to his faith. It is probably the case, while expecting much, he has prepared for nothing. New hives were needed for the increase of his stock when none were ready. The boom of the honey harvest came when no section boxes were prepared, and the manufacturers were too busy to fill an order without great delay. Frames were needed for newly captured swarms, but had been forgotten until too late. When foundation, would have been most advantageous to the busy workers, none had been secured.

He writes in his note book "too slow; bees, like time and tide, will not wait." Forewarned, he determines to be forearmed; there is great hope for him now. The result of his thinking will be that he must be always systematically ready.

For every colony that a young bee-keeper has he will require at least three fully equipped extra hives ready for use at a moment's notice. Thus, no contingency of swarming, dividing or creating nuclei will catch him unawares. He should have a light box or basket of proper dimensions, to take swarms from the branches upon which they may cluster. He should have a good smoker to subdue obstinate colonies. Also, an overplus of broad frames and section boxes with separators and starters, in case of unexpected yields of honey. He

should be properly supplied with both brood foundation and thin white foundation for starters in sections. He will also need a box of apianian tools containing hatchet, hammer, chisel, cutting nippers, pliers, two or three sizes of awls, small saw, strong pocket knife, some eight-penny finishing nails, small wire nails of three or four sizes, the largest, say three-quarters of an inch; some twine, and such other things as, in the course of practice, will be gathered together.

Thus equipped, with everything in its place, he will be prepared for any emergency. The first experience will teach him, if watchful, how, where and from what, honey is gathered. He will soon learn to distinguish, both by appearance and taste, that which is gathered from early fruit blossoms, white clover, linden, later flowers or buckwheat. With this knowledge, the second season will show the value of an extractor, by which honey can be taken as it is gathered, and each kind and quality can be kept separately. He will gradually learn that bee-keeping is not play, nor, upon a moderate scale, is it labor. It can be pleasure or profitable recreation, but it requires readiness, system and vigilance—excellent qualities even for persons who are not bee-keepers.

Preparing for Winter.

L. R. JACKSON.

Successful wintering of bees, in the North, is one of the most important subjects with bee-keepers. This, I think, is any easy thing to do, if we commence in time to prepare for the coming winter. I have always commenced in June to prepare for winter, and have always been successful in my 8 years experience, having never been troubled with "spring dwindling" but one year, and that was when I fed the bees with rye flour early in the spring.

Honey contains sugar in two forms: Cane sugar and grape sugar. Clover honey contains more cane sugar than fall honey, and is more easily and more thoroughly digested than grape sugar, or fall honey, and should be used for winter stores.

Our bees now have honey enough to winter them, with all the increase we shall have, and, as soon as it is well ripened, we will put away 2,000 pounds for winter. Then we can take honey with no fear of our bees starving next winter.

I have never known as good a prospect for a large crop of honey as we have this year, or known bees in a better condition for gathering it than they are now. Nearly all our bees are working on 20 Langstroth frames, and are crowding the queen, in spite of all we can do, unless we extract the honey before it is ripe, which it will not pay to do.

We have rain about three days in the week, yet it does not seem to stop the flow of honey as it usually does. I had prepared to run the bees for in-

crease until I saw what the harvest was going to be, when I changed my plans, and it has crowded me with work, so that I have had to hire extra help, and work from 4 a. m. until 8 p. m. to keep up with the bees.

I have given a few hints for wintering, which can be understood by any who wish to profit by them, and in September I will give my plans for packing.

Urmeyville, Ind., June 11, 1883.

[By an accident, after the type of last week's paper was "on the press," a part of the above article was "smashed," and could not be read; we therefore give it another insertion, so that those, in whose papers it could not be read last week, now have it with that "smash up" restored.—ED.]

Planter's Journal.

Extracted vs. Comb Honey.

O. M. BLANTON.

In almost every bee-keepers' association the question arises: "Which is the most profitable, extracted or comb honey?" Beyond a doubt, in my mind, extracted honey, especially in the South where the honey in the latter part of the season is dark and of a strong flavor.

1. The yield is from two to three times as much, and the same comb can be used again and again for the bees to fill, thereby enabling them to gather honey and lose but little time in the secretion of wax to build comb, as only a little is required for repairing and capping it.

2. Swarming is more easily controlled, as you can extract the honey from all the combs if necessary, which conduces more to keep the bees to their work than anything else.

3. The frames and apparatus required for extracted honey are more simple, and admit of more ease and rapidity of manipulation, thereby enabling the bee-keeper to handle and manage almost twice as many colonies.

4. The apparatus is far less expensive, as you are able to dispense with honey-boards, glassed section boxes and frames; the latter you lose in shipping.

5. The loss of comb foundation and comb, which is invaluable, especially when you are aware that the combs can be filled often, as much as fifty times before they are too old for the bees to use.

6. You can make more early shipments of extracted honey. In fact, I often begin to extract by the 1st of April, and have never taken off comb honey before the month of June, and but little until July.

7. Packages for extracted honey cost far less, as you can put it in barrels of 45 to 50 gallons, that do not cost more than \$2; where comb honey requires cases nicely finished with glass, and demand great care in packing and handling in transit to market. In addition the freight charges are so much less for barrels.

Bees are loth to work in small section frames, and often when they have partly finished capping the combs in the section boxes, the large frames in the brood-chamber are filled so much with honey that the queen has no place to lay, and the bees must swarm. If you extract from the brood-chamber, the chances are that the bees will fill the cells with honey before they commence work again in the sections.

There is this objection raised to extracting, that there is too much pollen left in the cells to become old and unfit for food. Such is necessarily the result of working for honey instead of great increase of swarms. Any thoughtful apiculturist will always reserve a certain number of colonies for increase.

As to the objection that colonies are robbed so close in extracting, that the bees are left without honey to winter on is too ridiculous, as none but he who is careless will fail to provide sufficient honey for the winter, and see that it is placed in the brood-chamber. No bee-keeper should fail to handle and closely inspect the combs in the brood-chamber.

Those who advocate comb honey for profit, in the South, have a poor conception of progressive and profitable bee-keeping. Comb honey is a fancy article that fluctuates greatly in price (from 10 to 25 cents), whilst the extracted is a staple article of commerce, and brings promptly in the market from 7 to 10 cents per pound.

For profit, extracted honey far surpasses that in the comb, and a bee-keeper who understands his business, and extracts as rapidly as it is gathered by the industrious insects, is on a fair road to fortune, especially if he uses the 20 frame one-story Langstroth hive.

Greenville, Miss.

For the American Bee Journal.

Florida for Honey Production.

W. S. HART.

Within the past two years there has developed a great interest among Northern bee-keepers in regard to Florida as a honey-producing State. Having had considerable to do with exciting that interest, by writing up our apianian resources for Northern papers, a large portion of those who visit the State either write to me or call upon me, and I find that the impression seems to prevail that my immediate neighborhood is the best and almost the only honey-producing section of this State. The consequence is, that bee-keepers are crowding in here to such an extent, that I honestly believe that unless there is a check put to it, the pasturage will be over-stocked within twelve months so as to greatly reduce the profits of the business. So far as my interests go, I am glad to see the country fill up with bee-keepers, or any other good citizens, and I have labored for years to accomplish that object, but, to the man whose only income is from

his apiary, this is a matter of serious consideration.

I know it has been claimed that it was almost impossible to over-stock this "Bee Belt," as it has been called, and as it has been stated to extend from Port Orange on the Halifax river, 125 miles south to Oak Hill on Mosquito Lagoon, it certainly does seem as though there was room for a good many yet. But instead of 125 miles, the section spoken of is really but about 18 or 19 miles. Then comes a break in the black mangrove, of some miles, and the next good location for an apiary, with a view to the mangrove pasturage, is some distance down the Indian river. That the black mangrove is our best honey-producing tree, is beyond a doubt, but that there are plenty of locations in the State, far away from any mangrove, in which bee keeping can be made more profitable than it usually is in the North, is also beyond a doubt, in my mind at least.

Until all the coast and Salt River of south Florida, where the black mangrove grows, is taken up and occupied by practical apiarists, I would recommend that section, but as I find the black mangrove sections are more limited than I formerly supposed, I will say a word for other pasturage.

Our hammock lands are rich loamy spots of from one to several thousand acres each, scattered about over the State. This land is covered by a heavy growth of cabbage palmetto, basswood, hickory, oaks, prickly ash, necked wood, youpon, white maple, bays, etc., etc., all of which have a greater or less value as honey producers. These hammocks are surrounded by pine woods or savannas. In the former are to be found the saw palmetto, gallberry and other good honey-producers, and in the savannas are the willows, for early pasturage, and later, a perfect sea of wild sunflower, for a late crop, besides innumerable small flowers.

If with all these resources to draw from, a few colonies of bees cannot do well, when properly cared for, near almost any of these hammocks, I am certainly greatly mistaken, but if that were the case, then, with our climate exempting us from all wintering troubles, and giving us nearly the whole year to work our bees in, with cheap living, cheap transportation, and other advantages too numerous to mention, I see no reason why a person cannot locate in the pine woods in sections where there is naturally but very little honey produced, and there plant just what he wants his honey from, in such a way as to give a continuous flow nearly the whole of the year. I believe this will be done before many years, for, if it will pay to plant for honey in the North, it seems to me it will pay better here. I am now trying sweet clover, Simpson honey plant, and spider plant; the seeds of which were kindly sent to me by a gentleman in Cincinnati.

Now, in reference to C. H. Lake's article in the BEE JOURNAL, April 25, page 213, I will say, as he got his information from correspondence alone, he has naturally fallen into some

errors which, as I feel sure that Mr. Lake would wish it, and as it might, as it stands, mislead parties coming to this State, I take the liberty of correcting and commenting upon as follows:

1. The length of the "Bee Belt" is some 18 or 19 miles instead of 125.

2. There is quite a tract of black mangrove at Indian River narrows, and more or less all along the river, although in many places the red mangrove predominates. On many portions of the river the black variety is too scarce to be of much value for honey.

3. Mr. Olson is quoted as saying it is "impossible to over-stock the country." Now, if *the country* means the "Bee Belt," there certainly must be a mistake some where, for this section of Florida *can be very easily over-stocked*, and Mr. Olson knows it, and, being a strictly honest man, he would not intentionally make any statement that would convey the idea that the above quotation does, or at any rate, not since he got well posted as to the resources of this country. While the mangrove is in bloom, it seems almost impossible to get bees enough to gather it all, but bring enough bees here to gather one-half of it, and bee-keeping would be reduced to a poorly paying business. Much less than "90 per cent." of our season's crop is mangrove honey.

4. The cabbage palmetto produced much less honey last season than usual, but considerable pollen was gathered from it. This may have something to do with the diversity of opinion in regard to its value.

5. Our prospects for first-class transportation by the middle of summer, is now very good. A railroad and the coast canal are both within a short distance of the Halifax river, and will soon be through to it.

6. Messrs. Alderman and Roberts, of Wewahitchka, Fla., have reported 350 colonies, which, I think, must be the largest apiary in the State.

7. Mr. Chas. F. Muth has praised our honey without stint, and has gone to great pains to put it before the public. In reply to a note and some samples of our honey sent by him to Rev. L. L. Langstroth, the latter wrote as follows:

OXFORD, NOV. 16, 1882.

FRIEND MUTH:—I have delayed giving you my opinion of that Florida palmetto honey until I could get the verdict of others besides myself as to its merits. Its color is unexceptionable, and its flavor very pleasant. I am not sure but that the majority of consumers will consider it equal, if not superior to white clover honey. Our Southern friends are to be congratulated on being able to supply our market with such a choice article.

L. L. LANGSTROTH.

Any one that would ask for a better endorsement than that, would be altogether too particular. It will sell my honey in any market of the world at top prices. I feel that the thanks of all Florida bee-keepers are due Mr. Muth for his kindly interest and efforts on our behalf, as by them our

honey now has a market proportionate to its quality, while formerly commission houses would take advantage of the old phrase, and when honey was quoted 11 and 12 cents per pound, they would make returns thus: "Gallons Southern strained honey at 80 or 85 cts. per gallon;" and this in spite of all we might say about "quality" or "extracting."

8. If Mr. Olson stated in his letter to Mr. Lake that he "made 6 swarms from one colony this season, and took from the old colony 440 pounds of extracted honey," he certainly wrote what he did not intend to. He meant to have said that he took 440 pounds from the old colony and its increase. Now, as I know Mr. Olson to be an upright and honorable man, and I believe Mr. Lake to be the same, and that only good was meant by his letter, I want it understood that the foregoing is not intended to reflect on the honesty of either party in the least, but that the discrepancies arise through Mr. Lake's not getting the exact ideas intended by the writers, or some carelessness on the part of the writer, perhaps. Such misunderstandings are very common. Mr. Lake's letter is interesting, and I can endorse all it says, with the exception of the above mentioned errors, which only serve to bring out more facts. There is still plenty of room for practical bee-keepers in this State, if they will only look up the locations.

New Smyrna, Fla., May 14, 1883.

Read before the Texas Convention,

Enemies to Honey Bees in Texas.

B. F. CARROLL.

In choosing the above for a subject, it was in hopes that I might bring something before you that would be of interest to the bee-keepers of our noble Lone Star State, and I will, mostly, confine myself to what I have seen in my apiary since I began the cultivation of the honey-bee, on modern principles, in 1869; at which time I was using the old "log and box gum."

My first notice was the destruction of several colonies by the moth. It was my custom to knock off the tops of the log or box gums and cut the honey out until I reached the brood nest, and often the honey would run out at the bottom, and as anything sweet will draw the moths, in large numbers, they would flock around the hives about nightfall, and find plenty of bits of comb cut down by the bees in which to deposit their eggs, which would so demoralize the colony that they invariably fell a prey to the ravages of this insect.

I luckily saw the advertisement of H. A. King & Bro., of Nevada, Ohio, in some agricultural paper in 1868, offering hives, etc., for sale. I ordered 13 American hives, and in 1869 I had them full of bees, and but little trouble did I have from them, until I introduced the Italian, Holy Land and Cyprian bees, and especially the latter in 1880. I have not seen a single colony infested by these dirty-

looking worms, and I no longer consider the bee-moth an enemy, but really an advantage, for they are rapidly driving box-hive men into our ranks or out of the business, and the little black bee, like poor "Lo," is westward going.

The next enemy to which I would call your attention, is the *Asilus Texanus* (*Misouriensis* Riley) or the Texas bee-killer, which I find more destructive, and in larger numbers, than any bee-killer I have seen. The *Asilus Texanus* is a two-winged fly of the predacious family *Asilidae*, and takes the bees in his long front set of legs and leisurely sucks all the juices from the bee. His legs being so long that the bee cannot get at his body while in captivity, but I have frequently seen my "Cyprians" capture, ball and kill these insects in its attempt to take a bee from the front of the hive. I find these insects more numerous in dry, hot years like 1881. That summer I killed over 100 in an hour, and every fly had a bee. They not only attack the bees about the apiary, but I have seen their nefarious work in the horseman fields.

You will find this insect described as beneficial to the agriculturist in the "Report of the Commissioner of Agriculture for 1879, plate XI, figure 3."

There is another bee-killer, or rather a large fly that is tolerated by the bees, to hang around, not knowing that these innocent-looking creatures will let fall a tiny egg upon their body that will hatch into a devouring grub, which bores into the body of the bee, where it lives on its vitals, which it soon destroys. This fly, I think, is described by Prof. A. J. Cook, ex-president of the N. A. B. K. Association, as the *Tachina* fly, and is also described as beneficial to the agriculturist (see Report of Commissioner of Agriculture for 1879, plate XIV., figure 2). I hope this last named insect may stay in the cotton fields where it belongs, for if it should visit our apiaries, in large numbers, we would have to "hang our harps on the willow trees" and give up our lovely pursuit.

The mosquito hawk, *Libellula* (see same Agricultural Report above mentioned), is another great enemy to our pets, and last September and October were present every evening, in alarming numbers, ready for a feast on the heavily laden bees as they came in. These insects can be driven off and killed in large numbers with long switches and whips, and is fun for the juveniles. They lay their eggs in ponds of water, by a peculiar dipping motion, where the young larvae feed on their insects.

The next enemy we will notice is the *Mantis Religiosa*, or more commonly called "Devil's horse." These formidable insect eaters are of such vast advantage to our orchards and vineyards, that I am in favor that we overlook his occasional meal on our pets.

A very small bronze-colored fly, and I think it is the same fly that lays the eggs on the locust, that destroys so many of them, has made its appear-

ance in my apiary, and I have seen it on the body of the bee, and from the antics cut by the bee, I fear it, too, is of the *Tachina* family, and that the eggs will produce grubs in the bee.

I have given you a few of the most formidable insect enemies to the honey-bee, that has come under my notice, and I will mention a few others of a different species. The English sparrow, mocking bird, and the martin of the feathered tribe I have caught eating bees, and particularly the mocking bird. I have watched these birds take a dozen bees or more before they are satisfied; they are very fond of drones, and it may be possible the largest amount of bees they eat are drones.

Toads, ants and spiders kill a few bees, but these are so easily dispersed that they can hardly be classed as enemies. I never kill a toad, but carry him to the garden where his presence is of greater importance than in the apiary.

For the destruction of the large red ants I use cyanide of potassium (poison) 5 ounces to 5 gallons of water; for small ants, salt and wood ashes.

And lastly comes the greatest enemy of all, and let us give him the dignified name of *Bonus Homo et Nobis Amicus*, his work is sure, and always leaves this epitaph behind: "Here rests, cut off from useful labor, a colony of industrious bees, basely murdered by its ignorant and ungrateful owner."

"Ah, see, where robbed and murdered in that pit,
Lies the still hearing hive! at evening snatched,
Beneath the cloud of guilt-concealing night,
And fixed o'er sulphur! while, not dreaming ill,
The happy people, in their waxen cells,
Sat tending public cares.
Sudden, the dark, oppressive steam ascends,
And, used to milder scents, the tender race,
By thousands, tumble from their honied dome
Into a gulf of blue sulphurous flame."

Killing bees for their honey was unknown in the days of Aristotle, Varro, Columella and Pliny, and must have originated in the dark ages, when the human family had lost in apian pursuit, as well as in other things, the skill of former ages. We are told that the old cultivators took only what their bees could spare, killing no colonies, except such as were diseased.

I am happy to see that this inhuman and cruel practice is fast giving away, and wherever bee papers and movable frame hives make their appearance, this practice ceases immediately. The spread of apistical knowledge is a sure remedy to the dreaded enemy last named. I feel proud that the Texas State Bee-Keepers' Association is doing a noble work in the advancement of apiculture in Texas; a State that is soon destined to lead all the rest of her sister States in this branch of rural economy. Patent-hive venders, that swarmed through our State a few years ago, have ceased to put in an appearance. Bee periodicals, assisted by a score of agricultural papers, have educated the people. Let the good work go on until our land and country shall flow with "milk and honey."

Dresden, Texas.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Rearing Queens.

Will Mr. Heddon please answer the following questions:

1. Can pure queens be reared from eggs layed by a hybrid mother? If not, what kind of queens would those three-banded workers have given.

2. When a queen fails, does she fail at once, or gradually? I have had queens that were good layers until, all at once, they would quit and lay no more.

3. What has been your experience with queens reared naturally or artificially—are those cells reared under the swarming influence any better than those reared artificially?

4. I have several queens which are three-fourths Italians, or more, would you advise rearing queens from these, to get the best honey gatherers?

Goshen, Ind.

H. J. SCHROCK.

ANSWERS.—1. The Italian race has physiological and mental markings peculiar to itself. When crossed with another race of different traits and markings, the offspring of that crossing, by the second law of evolution, inherit variedly more or less of the characteristics of either or both races. A bee, whether a worker or queen, can possess three golden bands, and yet be a hybrid, but no bees with less than three bands, are called pure Italian. An egg laid by a hybrid queen, while it might hatch a three-banded worker, should not be expected to produce a queen or worker truer to the traits of character peculiar to that race than the egg in an adjoining cell which might produce a bee of but one band.

2. Queens usually give out, seemingly, all at once; at least so suddenly that it seems so to the bee-master.

3. I have never made any thorough and pointed experiments upon this subject, nor do I believe any other bee-keeper has. This I will say, I have gathered a feeling from observation and experience, as I have traveled up the hill of apiculture, that queens reared under the swarming impulse are better than those not so reared. I find that if I go to a colony of any kind or size, at any time, and remove the queen, they rear no such queens as the same colony will when they do it of their own accord, with the queen in the hive. The cells do not look as good. I also know that since I have been producing queens under the swarming impulse only, my

bees are much better than before. Of course I have been breeding more closely for qualities; at the same time my prejudices, whether right or wrong, allow me to start no queen cells other than by the will of the bees.

4. If your hybrids are crosses between the larger brown German bee and longer-bodied leather-colored Italian, crosses produced in company with your judgment, and you desire a strain of bees for qualities, I should, by all means, breed from your queens; otherwise not.

SELECTIONS FROM OUR LETTER BOX

White Clover Rich in Nectar.

The honey boom has struck us here since the rain stopped, four days ago, and, if the weather continues favorable, the conditions are very promising for a large yield of honey. White clover is very abundant and rich in nectar, and, what bees are left, are doing finely. I had 43 small colonies left, out of 63 last fall. Many have lost all. Basswood will probably not bloom before July 20.

W. H. S. GROUT.
Kennedy, N. Y., June 25, 1883.

Report of the Buckhorn Apiary.

In November, 1882, I packed 39 colonies in my bee cellar; all came out in splendid condition, with only a loss of two queens. I began this season with 38 colonies; they commenced swarming June 16, and there are 1 or 2 swarms every day; they are carrying in honey at a great rate, and have filled some half-pound sections nearly ready for the market. My bees are very busy on red and black raspberries. The white and Alsike clovers are out in full bloom, and basswood is budding full.

F. A. GIBSON.
Racine, Wis., June 23, 1883.

Importance of Universal Frame.

I see in the BEE JOURNAL, a subject is being discussed by bee men that has interested me from my first experience in bee-keeping (as a pleasure more than profit); that subject is the "Standard frame." Now, it is very natural, when this subject is brought up, for each one to say: My frame is good enough for me; but if we would stop to consider, I think all would admit it to be a priceless boon to the bee-keepers of this country, could such a system be inaugurated. Suppose I wish to sell a few hives of bees, my frames are 12x12. B. would like to buy, and would pay a good price, but he uses the Langstroth frame, and could not afford to pay much for them, as he would have to transfer them, so both have lost a profitable sale in not having the same size of frame. I have wished to get a frame

of drone brood from a dealer, but as he did not state the size of his frames, I wrote him to learn this, and found he used the Gallup, so I was again disappointed, and he lost a sale. I think the "coming bee" would be sooner attained, for the "crossing" could be better accomplished. But as I am not much of a bee man, and much less a newspaper one, I will leave it for others, more competent; hoping the union may soon be effected, for I am looking for the pleasant day to arrive when I can leave the "throbbing mighty engine" and be with and hear the happy hum of the "blessed bees."

A. P. LANTERMAN.
Pullman, Ill., June 26, 1883.

Buffalo Clover.

I enclose two clover heads, which please give the name of in the BEE JOURNAL. It grows on rich soil, has a coarse foliage, and the bees work on it splendidly. One head is full size—the other is just coming to bloom.

W. MALONE.
Oakley, Iowa, June 18, 1883.

[It is Buffalo clover or *Trifolium reflexum*. This plant is much more common in the Southern States of the Union, being quite rare in the North from New York westward. It is an annual, or sometimes biennial plant of vigorous habit, and undoubtedly a good honey producer. The flowers are larger than those of the common red clover, but shorter, so that the nectar is accessible to the hive bee, whose visits materially aid the fertilization of the seeds. The heads are especially distinguished from those of red clover by the pedicels or little stalks upon which the florets are raised.—T. J. BURRELL, Champaign, Ill.]

Storing Honey from White Clover.

Bees are doing well here, at present; they are storing honey from white clover, which is plenty. I have one colony working in 72 one-pound sections. My bees came through the winter and spring in good condition, considering the cold winter and late spring.

ALFRED GANDER.
Adrian, Mich., June 25, 1883.

Honey Prospects Good.

Wind and rain appear to be the order of things in these parts; at least so much so that bees cannot work half the time. Bees wintered well, and are now in fine condition, but have not swarmed much yet, on account of its being so cold and wet. We never before saw the like of white clover, and it put in an appearance a week earlier than last season. If the weather gets favorable, the white clover honey crop will be immense. Bee-keepers are feeling good over the prospects, and are laying in heavy for supplies, for the prospects are good for the largest honey crop ever gathered in these parts.

A. W. FISK.
Bushnell, Ill., June 18, 1883.

Bees Doing Well.

Bees are doing very well here this year. There is any quantity of white clover, although we are having rather too much rain. I began with one colony in the spring of 1882. I now have 9, hybrids and Italians. I am using a side-storing hive, but I see from the BEE JOURNAL that most of the bee-keepers prefer other kinds.

J. C. TANNER.
Huntington, W. Va., June 25, 1883.

Bees so Busy as to Forget to Swarm.

This is a most beautiful morning. My bees are booming; they are gathering honey so fast that they forget to swarm. I have only had about 20 swarms from 200 colonies, although I have prevented swarming as much as I reasonably could.

A. SNYDER.
Clarksville, N. Y., June 24, 1883.

My Last Year's Work.

I commenced the spring of 1882 with 10 colonies; increased to 24; had 1,030 pounds of honey, in one-pound sections; and sold it at 18 cents per pound. I packed 10 colonies in sawdust, and 14 I wintered in a cellar. I lost one packed, and 7 that were wintered in the cellar, all by spring dwindling. I have had, to date, 6 swarms. The weather has been unfavorable, until within a few days; but bees are working nicely now, on white clover.

WM. PENNEY.
Shiloh, Mich., June 21, 1883.

The Bee Moth.

Please publish in the BEE JOURNAL the essay given by Judge Andrews, at the Texas Convention, and oblige many subscribers.

JOHN H. CHRISTIE.
Dyersburg, Tenn., June 21, 1883.

[We will do so, with pleasure, if the Judge will kindly send it for publication.—ED.]

My Spring Report.

My report from Jan. 1 up to date, is as follows: On Jan. 1 I had 90 colonies; I sold 30, leaving 60 to begin with. I had 10 good swarms early in April, and the hives are all full of bees. I increased them to 99 colonies. I have had to feed these, to keep them alive until the horse-mint flow began; it is now here, and nearly gone, and not one pound of honey have I had yet, but I think I will get my bees all built up strong before the flow is gone, which will be 10 days yet. If I only had plenty of bees I could get a little surplus, but bees have dwindled badly. Some brood chilled during the frosty weather, in the latter part of May. There is not one stalk of mint, this year, where 20,000 stood last year. I have about $\frac{1}{4}$ acre of catnip, which I planted in rows and cultivated; if I had 10 acres, I could not be found now with blasted hopes. A few hills of sweet clover 5 feet high are covered with bloom and bees too. The California pepper tree is also in bloom. We could have perpetual bloom here for 6 months, and often 9 months. There is a field of mint, of 30 acres,

some 4 miles off, as thick as wheat, and 4 feet high. This field was plowed last fall, and on account of the cold wet spring, followed by 8 weeks of drought, it could not be planted. Mr. W. R. Melton, who lives 400 yards from that field, has 100 colonies of bees that are simply booming, so you see it *pays to plant for honey*, wet or dry. I can go to the woods and hunt wild bees for the wax and bees, for a pastime; and when the old, tried, true and trusty friend, the BEE JOURNAL makes its weekly visit, I have time to read all, even the letters about cellars and chaff and all other such fixings that "we 'uns, down here," know nothing about practically. It makes me feel glad to hear such good news from Kentucky, "Bee-keepers all worked down," "Honey flow enormous." My time next, brother, you see.

B. F. CARROLL.

Dresden, Texas, June 18, 1883.

Bees Gathering Honey.

We have now had nearly a month since it became warm, and during this time there has been but three days that it has not rained at some time during the 24 hours, and many of the days it has "rained all day." On the night of the 18th, 3 $\frac{1}{2}$ inches of water fell upon a level, and this, with the ground already soaked, caused our streams to rise up to high water mark. But little corn and potatoes have been hoed, and the fields are nearly as green as meadows. Plenty of white clover is in bloom, but it is of no use to the bees, which I am feeding to keep them from starving.

LATER.—We have had 4 days of good weather now, and the bees are getting a living, and storing a little in the body of the hive.

G. M. DOOLITTLE.

Borodino, N. Y., June 26, 1883.

Generous Honey Season.

The honey season here was never better. The flow is generous, and the quality is most excellent. The swarming impulse has been simply rampant. My apiary has sent out bees with the energy of a Vesuvius for three weeks past.

G. W. DEMAREE.

Christiansburg, Ky., June 22, 1883.

Rain, Rain.

"It rained 40 days and nights." I would like to know if there is any account as to whether Noah fed his bees on granulated or grape sugar, to preserve them through that spell of wet weather?

J. G. WHITTEN.

Genoa, N. Y., June 26, 1883.

[We give it up.—Ed.]

Straight Combs, etc.

I have one colony of bees which have the frames and combs all connected together, will some reader of the BEE JOURNAL inform me how to get them apart. It is a Langstroth hive. I also wish to know how to get my bees to build their combs straight.

J. HURST.

Minooka, Ill., June 21, 1883.

Bee-Keeping in Maine.

The bee business is increasing very fast in this part of the State; new land clover, and acres and acres of fire weed furnish abundance of honey of superior quality, bringing the highest price in the market. The only drawback that we have had in the past year, is the hives that we have had to use. Being so far from any of the manufactories of bee implements, we have had to use anything we could get for a hive, now we are better prepared, as a manufactory has started near us. This is a help to us here, and will greatly improve the business. I am not prepared to furnish much in regard to the statistics of bees or honey, but I will hereafter gather what I can and send you. It is a good thing to hear a little news from every one having bees, as we do not all get experience alike, and we ought to give ours to others.

O. B. KEENE.

Fort Fairfield, Maine, June 16, 1883.

High Aspirations.

Several of my bees have selected the highest tree in my yard to alight upon, when swarming, out of the reach of a 26 foot ladder. Why they should select such a high point, I do not know. Two of them have selected the same limb, about 40 feet from the ground, but prematurely, as "their mother did not know they were out." I was obliged to let them hang until they found that their mother was not out, then they returned home, if not sadder, perhaps wiser; so, I may have another chance at them. Why is it that one of my colonies seem to be full of the Old Nick. I cannot touch them with a 10 foot pole, as a dozen will start for me at the same time? It is one that was partly robbed last fall, and was attacked this spring again; but with judicious care and good feeding, I brought them through, and even now they do not appreciate my good intentions. I was obliged to use the "Conqueror," that little engine of smoke, upon them; which brought them to terms. What would the apiarist do to-day without the smoker, at this advanced age of apiculture?

JOHN GOCHENOUR.

Freeport, Ill., June 25, 1883.

[Robbing has been the cause, no doubt, of angering them. The smoker, judiciously used, will conquer them, however.—Ed.]

A Lively Rushing Season.

Our swarming season is just over, and we are not sorry, as we have not hardly had time to breath, working day and night; the bees began to swarm on April 1, and continued up to June 10. We have more than doubled our stock, while doing our best to prevent swarming. The Italian queens we got from the BEE JOURNAL apiary, two years ago, are good workers, and right on the swarm. We have had them fill a 2-story hive in a week without the aid of foundation, being 80 pounds of honey in all. We took the comb all

out of the second story, threw out the honey, and gave them foundation, and in three days they had all filled again and swarmed. We are getting 1,000 two-pound sections of comb honey each week, and every 8 days, 1,200 pounds of extracted honey. We only run 40 hives for extracted, the balance for comb honey. We find it very difficult to run for comb and extracted honey in one apiary; so, next year, we intend to start another apiary of 300 hives for extracted honey only, with all improvements, such as evaporating tanks, etc. We intend, of course, to retain our present apiaries for comb honey, as there is a good market for No. 1 comb honey, and we put up a first-class article. Can you inform us if there is any machine which makes a No. 1 article of section box foundation and brood chamber foundation, both being made on the same machine? We think there can be a machine to make both by having two sets of rollers. If we do not have any set back, we shall have a full crop, and the bees will store honey up to October. BRAY & SEACORD.

Warthan, Cal., June 15, 1883.

[We think both kinds can be made on the Vandervort mill, and, perhaps, on them all, by having the sheets of wax thinner. Will some one having experience please reply to this.—Ed.]

Bees Working in the Second Story.

After selling some bees, I have 23 colonies left. I have not had a swarm yet, but I have nearly all working in the second story, for extracted honey. They have done well for about a week. We have had a cold, wet spring, and it is raining yet, about every other day. It is too wet to do anything on the ground. White and Alsike clovers look well, and are now in full bloom. My bees are in a better condition than I ever had them. I lost about 1 out of 6, this winter and spring. I put my bees in the cellar late in the fall, and took them out on March 13. I have given up uniting bees in the spring; I think it is a failure to do so. I have an imported queen, but I do not sell queens.

E. S. HILDEMAN.

Ashippun, Wis., June 23, 1883.

White and Alsike Clover.

Never was such a sea of bloom known here before. White clover commenced blooming May 11, and it looks as if it was not at its best yet. We have a rain storm every few days, and it has done great damage, especially in creeks and river-bottom lands. It has killed nearly all the growing corn, and it looks as if it might continue to rain yet, for some weeks. The "blessed bees" make good use of every fair hour of daylight, gathering the sweets and swarming. My 51 colonies are booming. I have had 60 swarms, up to date, and I am extracting and taking off comb honey, to give them room. My swarms all return to the old stand, as I have clipped all my queens' wings. I do not think the clipping of my

queens' wings has caused any of their offsprings to be lazy, crazy, invalids or cripples. My Holy Land Italians beat all yet.

R. M. OSBORN.
Kane, Ill., June 25, 1883.

Texas Reports a Poor Season.

This is the worst season the bee-keepers of Central Texas have ever experienced. From my 40 colonies I have saved 6, and got 50 pounds of honey, with no hopes of anything further this season. But we do not give up the ship, and will organize a county association on the first Saturday in July, and have everything fully equipped for 1884. E. P. MASSEY.

Waco, Texas, June 26, 1883.

Local Convention Directory.

1883.	Time and Place of Meeting.
Aug. 29.—	Iowa Central, at Winterset Fair Grounds, Z. G. Cooley, Sec. <i>Pro tem.</i>
Sept. 12-14.—	Tri-State, at Toledo, Ohio, Dr. A. B. Mason, Sec., Wagon Works, O.
Oct. 9, 10.—	Northern Mich. at Sheridan, Mich. O. R. Goodno, Sec., Carson City, Mich.
Oct. 17, 18.—	Northwestern, at Chicago, Ill. Thomas G. Newman, Sec.
Oct.—	Northern Ohio, at Norfolk, O. S. F. Newman, Sec.
Dec. 5-6,	Michigan State, at Flint. H. D. Cutting, Sec., Clinton, Mich.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

A Card to Kentucky Apiarists.

The Kentucky State Bee-Keepers' Association will meet at the great Exposition building in Louisville, about the first of September next, the precise time will be made public soon. We want to make that meeting a respectable and useful one. In order to help forward the enterprise each proprietor of all modern apiaries in the State, is earnestly requested to address me a letter at Christiansburg, Ky., stating the number of colonies employed in his apiary, what race or strain of bees, whether he produces comb or extracted honey, or both, at what price does his honey sell, in what market he disposes of it, whether he has succeeded in building up a home market, what race or type of bees has given the best results, what per cent. of net profit does his apiary pay on the capital invested, and any other matter pertaining to the business which may be of interest to beekeepers and the public generally.

G. W. DEMAREE,
Pres. Ky. State Bee-Keepers' Ass'n.

The Marshall county Bee-Keepers' Association will meet at the Court House in Marshalltown, Iowa, at 10:30 a. m. and 1 p. m. Subject for discussion: "Summer care." Our last meeting was one of interest to all present. All parties interested in the busy bee in Marshall and adjoining counties, are invited.

J. W. SANDERS, Sec.
Le Grand, Iowa.

[We suppose this meeting is to be held next Saturday, July 7, but the secretary forgot to name the day.—ED.]

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Special Notice.—We will, hereafter, supply the Weekly BEE JOURNAL for one year, and the seventh edition of Prof. Cook's Manual of the Apiary, bound in fine cloth, for \$2.75, or the Monthly Bee Journal, and the Manual in cloth for \$1.75. As this offer will soon be withdrawn, those who desire it should send for the book at once.

Bingham Smoker Corner.

Large Smokers need wide shields. Bingham's have them, and springs that do not rust and break, and bellows that sparks and smoke do not enter. The Conqueror has all improvements made to date, and a 3x7 inch stove, and 5x7 inch bellows. Sent post-paid for \$1.75. Address,

BINGHAM & HETHERINGTON,

Abronia, Mich.

All Excelling. — Messrs. Bingham & Hetherington, Dear Sirs:—I am now selling your Smokers almost exclusively. You are excelling yourselves in smokers all the time.

Respectfully, J. G. TAYLOR.
Austin, Texas, May 10, 1883.

Cyprians Conquered.

All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am "boss." Bingham's "Conqueror Smoker" did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham.

G. M. DOOLITTLE.
Borodino, N. Y., Aug. 15, 1882.

During the following three months, Bingham Smokers will be sent post-paid, per mail, on receipt of the following prices:

The "Doctor" (wide shield)—3½ in. fire tube, \$2.00
The Conqueror (wide shield)—3 in. fire tube, 1.75
Large (wide shield)—2½ in. fire tube, 1.50
Extra (wide shield)—2 in. fire tube, 1.25
Plain (wide shield)—2 in. fire tube, 1.00
Little Wonder (narrow shield)—1¾ in. fire tube, .65
Bingham & Hetherington Uncapping Knife, 1.15

With thanks for letters of encouragement, and the absence of complaining ones, we tender to our thirty-five thousand patrons our best wishes.

Very Respectfully Yours,

BINGHAM & HETHERINGTON.

Abronia, Mich., June 1, 1883.

Sample Copies of the AMERICAN BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

"The Bavarian Apiary."

During a recent tour through Carniola, Austria, I made special arrangements whereby I now receive regular shipments of

CHOICE CARNIOLAN QUEENS.

Carniolan bees are large, strong, and, to my eye, handsome—being light-gray in color. They are the most peaceable bees I have ever handled, and even beginners in bee culture will find no difficulty in manipulating them without smoke, and without protection to face or hands. The Queens I send out are of the highest quality—large and prolific. I have also special contracts whereby I am supplied with

EXTRA FINE ITALIANS,

reared in those Alpine regions where I have found the bees to be the most vigorous and prolific. The workers of these Queens are as finely marked as any Italians in existence.

One queen in June or July, each.....	\$4.50
After August 1st, each.....	4.90
Five queens in June or July, each.....	4.05
After August 1st, each.....	3.60
Ten queens in June or July, each.....	3.60
After August 1st, each.....	3.30

Freight prepaid to New York city. Queens which do not reach the purchaser alive, if immediately returned by letter, will be replaced.

FRANK BENTON,

27Cct Georgenstr.4. MUNICH, GERMANY.

The American Apiculturist

Is a first-class 32-page Monthly, devoted to bee-keepers and their interests, edited and published by a practical bee-keeper. Its list of contributors is composed of the most scientific and practical apiculturists in the country. It is endorsed by our leading bee-masters everywhere.

The July number will contain the description and history of the **BAY STATE APIARY**, from which has emanated **Alley's new method of Queen Rearing**, as given in the "Handy Book," together with an excellent portrait of Mr. Alley and his apiary.

Those wishing to secure this number will please send their subscription for three months. Sample copies sent free. Do not fail to read our unparalleled offers to subscribers.

Subscription Price: **\$1.00** per year, payable in advance; sent on trial 3 months for 35 cents; 6 months for 60 cents. Address,

SILAS M. LOCKE, Editor and Publisher,
SALEM, MASS.

THE AMERICAN BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Adulteration of Sweets by Glucose— "They Make Money Out of it."

The manufacturers of that vile trash, glucose, are ever on the alert to find new excuses for adulteration. They now assert that pure honey when analyzed is found to contain "76 per cent. of pure glucose," and then foolishly advise the addition, perhaps, of 76 per cent. more of their *impure* trash to it, so that some one dishonest enough to take their advice, should "make money out of it."

Failing any longer to make it profitable for the "mixers," in the large cities, to continue their vile trade, they now desire to enlist bee-keepers to dishonestly feed it to the bees to store it, so that it may be sold for *honey*, and encourage them to do it, because they can "make money out of it."

What do they care if it does poison millions of bees while carrying and depositing it in their combs?

Why should they have any compunctions of conscience about its effect upon millions of human beings, wearing out their stomachs, entailing disease and death, if they can "make money out of it?"

The one result, "making money out of it," is the excuse as well as the reward for dishonesty.

The following communication from the able pen of the Rev. L. L. Langstroth on this subject, will be read with more than ordinary interest:

My friend Mr. D. A. McCord wishing to test the value of grape sugar, as a bee-feed, wrote to a glucose manu-

factory asking their prices. This reply came:

—Feb. 21, 1883.

DEAR SIR:—Yours of the 13th to hand. We will quote you glucose at 4½ cts. per hundred lbs.—in 100 pound kegs. You will find it fine food for producing honey, as pure honey analyzes 76 per cent. pure glucose.

Yours Respectfully,

THE GRAPE SUGAR CO.

Mr. McCord wrote again, stating that he wanted grape sugar for a spring bee-feed, and not glucose, and received the following:

—Feb. 26, 1883.

DEAR SIR:—Yours of the 24th received, and shall have attention. We think if you will try it, you will find that you can produce honey very fast, and of fine quality. They feed it very largely in California, and make money out of it. Would like to hear from you after you try it.

Yours Truly,

THE GRAPE SUGAR CO.

Following this letter came glucose instead of the grape sugar ordered. It was about as thick as good honey, and almost as clear as water. As the bees stuck fast to it and died, no use was made of it as a bee-feed. Its taste was sweetish and decidedly bitter. No name was given in the above letters but that of the Company, called after the place where their establishment is located.

Prof. Marsh, of the Miami University Training School, furnishes the following analysis of that glucose:

OXFORD, O., July 5, 1883.

DEAR SIR:—I have tested the sample of glucose syrup which you handed me for analysis, and find that it contains large quantities of sulphuric acid and sulphate of lime. The sample of pure honey was found to have a slightly acid reaction.

Very Respectfully,

B. F. MARSH.

L. L. LANGSTROTH, Oxford, O.

Line and free sulphuric acid! no wonder it has a bitterish taste. In order "to see what would come of it," Mrs. McCord used it in the making of some gingerbread. The product was poor stuff indeed—not having the ordinary sweetness of corn bread. It *puffed up* remarkably—a thing easily accounted for when the analysis showed how rich the glucose was in sulphuric acid. Syrups, etc., increased in volume by glucose mixtures, are no more to be

commended than this expanded gingerbread.

"Pure honey analyzes 76 per cent. pure glucose." One would think that if honey was so largely glucose, it would be scarcely necessary to add more to it! It has never yet been made to appear that glucose as pure as that contained in honey or fruits can be *cheaply* produced. If the time shall ever come when it can be, it would still be a fraud to use what has so low a sweetening power (only about one-third that of cane sugar), for adulterating molasses, maple syrup, sugars, candies, etc.

A friend of mine was told by the captain of a boat on which he was travelling, that he carried many barrels South to be used in adulterating their sweets.

Another friend informs me that he saw 40 barrels of glucose at one railroad station, all of which was to be used in adulterating maple syrup!

Mr. Chas. F. Muth, of Cincinnati, O., perhaps the largest dealer in honey in the West, and who has done so much, both by precept and example, to discourage the sale of adulterated honey, has had glucose recommended to him by large dealers in it, as a good thing to mix with honey, so as to "make money out of it." At one time he said to me, that in his opinion, most of the so-called maple syrup in the Cincinnati market was largely glucosed.

It is only within a short time that any quotations of glucose or grape sugar could be found in the grocer's papers. Will any advocate for their use, let the world know for what legitimate purposes the vast amounts made of them are used? Dare any one connected with the making of glucose, tell the public in plain words exactly for what purposes they are actually used? I fear not.

Confident assertions are not wanting, to show that only a pure and harmless article is made, and, you might imagine, that its makers are deeply grieved that this good creature of God is ever used by bad men for shameful adulterations. They would be ever so glad to put a stop to said doings if they could. Believe this, who can?

I do not know that hitherto any proof has been given to the public, that some, at least, who manufacture glucose and grape sugar, are acting the part of tempters, and even going so far as to suggest to those who wish to purchase them for a legitimate experiment, how money is to be made

by adulterating honey with their wares.—“There is money to be made out of it.” Does not such a way of doing business strongly suggest the crooked methods of those who deal in counterfeit money?

Business, in any proper sense of that word, means transactions between parties, where both buyer and seller are benefited by the deal. Tried by this standard, adulterators of the great commodities of life, will not seem to rise much if any above the level of gamblers, counterfeiters and cheats.

You will notice, Mr. Editor, that I do not give to the public the name—nor does Mr. McCord authorize you to give it—of the company with which he was in correspondence, for we do believe that this company is a sinner above all others who make the same products. The original letters are herein sent to you, so that in the mouth of at least three witnesses their genuineness may be established. Oxford, O., July 3, 1883.

The “original” letters sent to us by Mr. Langstroth, have been scrutinized and returned to him. They are correctly printed at the beginning of the above article. Just think of the villainy of asserting that “they feed it largely in California,” to deceive bee men in Ohio, and get them to engage in the nefarious business of adulteration!

No matter if the large trade in California honey is ruined by the circulation of this false report, so long as “they [the glucose manufacturers] make money out of it.”

It is high time that stringent laws were enacted and rigidly enforced against this hydra-headed monster adulterator!

Going South.—The *Planters' Journal* remarks as follows about bee-keepers emigrating to the South:

Large numbers of Northern bee-keepers are seeking the flowery fields of the South, where the bees find ample natural foraging ground, live all winter without being housed, and in various other respects prove more profitable to their owners. There is no earthly doubt but that the South is destined, and that at no distant day, to become the greatest honey producing and honey exporting country on the globe. We hope soon to see a regular Southward exodus of men and women engaged in this industry, from the North and Northwest.

Honey Shower.—John B. Drake, of Kappa, Ill., extracted in two days, recently, 600 pounds of honey from 12 colonies of bees. A pretty good example of the “honey shower” now existing all through the Northwest. Keep all the buckets right-side-up, to catch it.

A Few Pointers.

The *Grange Bulletin* contains the following under the caption of “Things about bees worth knowing:”

The mother queen leads the first swarm of the season, and the second as well as the third swarms, are led off by the young virgin queens.

Not one swarm in a hundred will go direct from the old hive to the woods if led by a prolific queen, but will settle near by, before taking their farewell leave of the old home.

It is always best to have your hives ready for taking care of your bees as soon as settled, if you allow them to swarm in the old pod-auger style. Always do your swarming in the proper manner and at the proper time, which would save many would-be runaway swarms if left to follow their own inclinations. Artificially swarm your bees.

It is a well known fact that bees never visit two or more distinct classes of flowers on the same trip, but always procure a full load of pollen or honey of which ever kind they commence on first, and return to their hive or home to unload before making a change.

Bees are very useful in the fertilization of flowers, seeds and plants, as well as being very necessary in the proper maturing of all classes of fruit, especially apples, peaches, pears and plums; also many other valuable and useful fruits of which we have not time or space to enumerate. Watch with care and you will learn many valuable lessons from your bees through the various departments of life.

Queens are produced from the common eggs that would have hatched worker bees if left in the common brood-cells and fed the usual food of honey and farina; but having been provided with a *royal cell* and also *royal paste*, as food on which they are bountifully provided, it transforms them into a royal queen, who is to be the mother of the future increase of the hive, or swarms.

Bee-Keepers' Picnic.—The *Indiana Farmer* gives the following as a partial report of a bee-keepers' picnic in that State:

The bee-keepers of Hendricks and Boone counties held a joint society meeting at the residence of Dr. J. H. O'Rear, at Lixton, June 23. The gathering was really a bee-keepers' picnic, and was well attended, bespeaking success to the Societies. Every subject of interest to bee-keepers of the present time was thoroughly discussed; the members showing a knowledge of the subject which can only be acquired by careful study and diligent inquiry. A committee of members from both Societies was appointed to arrange a second joint meeting of the Societies at some place in Boone county during July or August. Too much cannot be urged in the furtherance of meetings of this

kind. The plan has been followed by the many horticultural societies throughout the State, making them very successful and interesting to all concerned.

OBITUARY.—We are sorry to announce that Death has entered into the circle of publishers of bee papers, and snatched, as its victim, Mr. Theodore Houck, late publisher of the *Bee-Keepers' Exchange*, Canajoharie, N. Y., who died at Denver, Col., on Saturday, June 16, 1883, at the age of 26½ years. His death was quite sudden. The *Exchange* gives the following particulars:

We are reminded, in the death of Mr. H., of the frailty of this life. Up to the first of last January Mr. H. was a perfectly healthy man, having passed an examination just prior to that for a life insurance. On the 2d of January, Mr. H. attended the meeting of the Eastern New York Bee-Keepers' Association, held at Albany. He put up at a hotel that night, and was assigned a room and bed that had not been used for some time; the consequence was that he took a severe cold which settled on his lungs and hurried him to his grave with quick consumption. Mr. Houck was a thorough bee man, beginning when a boy, and continuing until his health gave out and death came. He loved the bees, and was never happier than when among them. His public career was short, about 18 months ago he purchased the supply business and *Bee-Keepers' Exchange* from Mr. J. H. Nellis, and conducted them up to within a few weeks of his death, his failing health compelling him to place them into other hands. He leaves a widow bowed down with grief, having in one short year buried her husband and little boy, their only child.

The BEE JOURNAL condoles with the stricken family in their affliction, and sincerely hopes that Mr. H. had, in life, provided for his family by obtaining the insurance policy mentioned by the *Exchange* in the above paragraph.

Lessons of Industry.—An exchange remarks as follows:

The bee has long been a type of the industrious worker, but there are few people who know how much labor the sweet board of the hive represents. Each head of clover contains about 60 distinct flower tubes, each of which contains a portion of sugar not exceeding the five-hundredth part of a grain. The proboscis of the bee must, therefore, be inserted into 500 clover tubes before one grain of sugar can be obtained. There are 7,000 grains in a pound, and as honey contains three-fourths of its weight of dry sugar, each pound of honey represents 2,500,000 clover tubes sucked by bees.

Bee Statistics in Germany.

Mr. C. A. Stoepel translates the following on this subject from the *Deutscher Bienenfreund*, for the *Bee-Keepers' Exchange*:

The census in Prussia, Germany, of 1883, shows a decrease in the number of colonies of bees kept since 1873. The whole number of colonies kept in 1873 was 1,461,055, and in 1883 are kept 1,232,231 only, a decrease of 228,824.

Mr. Suppea, a notorious bee-keeper, feels quite disappointed over these figures. He thinks that bee-keeping cannot be a paying business to many bee-keepers, or that the bee-keepers must have lost heavily during the last terrible winters.

He says that these figures are a scorn and sneer in the face of all the work done by the different bee-keepers' societies, and all methods set forth in many manuals on bee-keeping toward the advancement of apiculture. Probably these figures are a judgment on all the new-fangled bee-houses and foreign bees, or the result from low duty on foreign bees.

C. J. H. Gravenhorst thinks as a reason why bee-keeping has not been successful with many is, that there is no law protecting bees from the many dangers they are exposed. Lawsuits over the keeping of bees increase from day to day. Birds, although their benefitting the public, is sometimes very doubtful, enjoy such a protection, why cannot bees enjoy such a protection, as well as birds do?

At present there is a project of such a law, appended with 16,000 names of bee-keepers before the Reichstag, urging the same to be adopted as a law.

Why Bees Work on Sunday.—An exchange gives the following very silly story as a reason:

We have just been interrogated by one of our students who asks the question: Why do bees work on Sunday? To which we answer: In the beginning, God created all things perfect, and to the honey bee he gave an unusually keen acuteness of smell which enables them to become great foragers. And seeing that the red clover was a grand honey-producing plant, he also saw that the honey-bee was likely to outstrip all other insects in storing up large quantities of honey, especially so if allowed to work the red clover; and to prevent which he gave the hive bee its choice either to work on the Sabbath and let the red clover alone, or to work on the clover and rest on the Sabbath, the honey-bee preferred to work on the Sabbath and let the red clover alone. Hence, the reason the common bees of this country leave the red clover for the humble, or what we commonly call the bumble-bee, to work on. And thus the honey-bee is permitted to work on the Sabbath; while we, as his created beings, in His own likeness, are commanded to remember the Sabbath day and keep it holy.

Foul Brood.—Mr. E. W. Felton, of Hastings, Minn., has sent us a sample of what he thinks is the foul brood, with the following letter dated July 2:

I send a comb of foul brood, which I have had in my apiary for the last four seasons. The second season I undertook to eradicate it, and commenced Aug. 7, giving the bees clean hives and foundation, and scalded honey; but it was so late that they did not build up strong enough to winter without doubling up, which reduced them from 30 to 10, and the disease still remained with them. They increased from 10 to 16 last season, and gathered 800 pounds of comb honey and 200 pounds of extracted. I brimstoned them last fall, boiled the hives, burned everything else, and bought 30 colonies last spring; they are in the midst of white clover, and storing honey very fast, and no signs of foul brood yet. I let one of my neighbors have a few colonies last season, three miles from my place, they are doing well, and have no foul brood now. I would like to know if they ever get rid of it without any help. Will some bee-keepers, who have it in their apiary, give their experience with it?

Having had no experience with foul brood, we do not feel competent to give any advice or opinion. It is committed to the flames at once. We do not like it around, and hope our friends will not send us any more samples of it.

We have received a large pamphlet of 50 pages on the Honey Plants of Italy, enumerating them, giving their time of blooming, qualities for honey, etc. It is written by Dr. L. Savastano, and published at Napoli, Italy.

Imported Queens.—The Lexington, Ky., *Transcript* remarks as follows about an importation of bees just arrived at that city:

Messrs. Mucci and Frank Storm, of our city, brought into our office on yesterday, some bees that they had just imported from Italy. They had come by express in a neat little hive, with honey in it. They cannot speak a word of English, but they sting in the American language. The importation was solely for the sake of the queens that were in each little hive, and the few common bees sent along with them were simply as a retinue for their royal highnesses; the queens, like royalty, queerly preferring to starve to death rather than do any menial service for their own sustenance.

The queens are easily distinguishable by the practiced eye. A single queen bee imported to this city once cost Dr. Dillard \$30, beside a trip to Ohio to bring it here. Bees are imported here from Germany, Cypress,

Palestine and Italy. Those from Italy are the best workes, and are gentler than others.

A Sample.—By George.—The Fremont, Mich., *Indicator* says:

"The compliments of the season," was the inscription attached to a choice piece of honey from the apiary of Geo. E. Hilton, yesterday. George now has 43 colonies of bees, making his prospects for honey 'simply immense.'"

That is the correct way; Mr. Hilton has hit the nail on the head. Now, follow this up with some instructions about "Honey as food," and all the honey will be sold as fast as produced.

Do not let your numbers of the *BEE JOURNAL* for 1883 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL. }
Monday, 10 a. m., July 9, 1883. }

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY.—Extract, honey has commenced to come in freely, and a large crop is reported from all quarters. The demand is very good, and keeps pace with the arrivals. For choice extracted honey I pay 7¢@10¢; the latter price for choice clover. I have received several nice lots of comb honey, for which we paid 15¢@16¢ on arrival.

BEESWAX.—Arrivals of beeswax are plentiful. We pay 32¢. for a good article on arrival.

CHAS. F. MUTH.

NEW YORK.

HONEY.—Best clover in 1-lb. sections (no glass) 20¢@21¢; in 2-lb. sections (glassed) 18¢@20¢. Fair quality, 1 and 2-lb. sections, 16¢@17¢. Extracted, white, in small barrels, 10¢@11¢; buckwheat, 8¢@8½¢.

BEESWAX.—Is more plentiful. Prime yellow sells at 36½¢.

H. K. & F. B. THURBER & CO.

CHICAGO.

HONEY.—The demand for extracted is good, and the market bare of all unfarmed honey. Prices range from 8¢. to 10¢. Comb remains lifeless and will until the new crop comes, or until August. Sales of comb are being made at 8¢. to 15¢.

BEESWAX.—30¢@35¢.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY.—New extracted is arriving freely—selling for 7 and 8 cts. New comb coming forward slowly; extra white, 16¢.

BEESWAX.—No beeswax in the market.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY.—Some new comb jobbing at 14¢, but old do. nominal. Only a few barrels of extracted and strained sold within quotations—13¢@17¢.

BEESWAX.—Sold irregularly from 32¢@34¢—mainly at 32¢@33¢.

W. T. ANDERSON & CO., 104 N. 3d Street.

CLEVELAND.

HONEY.—There is a moderate sale for best white 1-lb. sections at 18¢, occasionally 19¢, but 2 lbs. are not called for. Extracted has no sale at all.

BEESWAX.—Not offering.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY.—Our market is fairly active. We quote: ½ lb. sections at 30¢; 1 lb. sections, 22¢@25¢; 2 lb. sections, 20¢@22¢. Extracted, 10¢, per lb. Good lots of extracted are wanted in kegs or barrels.

BEESWAX.—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatham Street.

CORRESPONDENCE

For the American Bee Journal.

Making or Forming Nuclei.

G. M. DOOLITTLE.

Every bee-keeper who expects to be up with the times, and make the most from his bees, should have on hand, at this season of the year, several laying queens, held in reserve to supply any colony needing a queen at a moment's notice; especially where any method of increase other than natural swarming is adopted, reserve queens should be kept on hand to be given to the queenless part of the divided colony.

In order to keep these reserve queens, it is necessary that we have a nucleus or small swarm of bees in which to rear them, from the time the queen-cells are ready to be taken from the colony producing cells, till the queen is fertilized and ready to become the mother of a colony.

Many ways have been given for making a nucleus of bees, most of which prove to be a failure, and result in loss with the inexperienced. The one most commonly given in our books and bee journals is to go to any colony which can spare them, and take a frame of hatching brood and one of honey, together with all the bees thereon (being careful not to get the old queen), and place them in a hive where you wish the nucleus to stand; thus forming a miniature colony of bees. The hive is to be contracted to the requirements of the nucleus, and in 24 hours a nearly mature queen cell is to be given. This looks very pretty on paper, but when we come to put it in practice, it is found that in nine cases out of ten, so many of the bees will return that our nucleus is practically good for nothing, and often results in the chilling of all the brood in the frame, if the weather is cold. The other day, while in conversation with a bee-keeper having several years' experience, more than the writer of this article, he remarked that his nuclei had "gone back on him," and when asked how he made them, he gave the above plan. I remarked that it was strange how young a bee would return to the old hive under such circumstances, when he said there was scarce a hundred bees left in his nucleus where he had put a quart or more.

If the above plan fails in the hands of a bee-keeper having 16 years or more of experience, how can it be expected that the novice will succeed with it? Several years ago, after repeatedly failing with the above plan, I had occasion to set a frame of bees and brood, on which was the queen, into an empty hive, and to my surprise nearly all the bees staid where I placed them. In a few days I returned the queen, and as the bees had become established in their new location, while the queen was with

them, a good nucleus was the result. Thus I learned how I could form a nucleus which could be depended upon every time. Another thing I ascertained, that a colony having queen-cells considered such cells the same as a queen, and by taking a frame of brood which had a nearly mature queen-cell upon it, together with one of honey, bees and all, from such a colony, a nucleus could be formed so that nearly all the bees would stay where placed. Thus to make several nuclei, all I had to do was to count the queen-cells in the hive about the time they were sealed, then go to the other hives and take frames of hatching brood (brushing off all the bees), till I had as many as I had queen-cells, and place them in the hive having the cells. Two days before the queens were to hatch, cut out the cells and fix one in each frame of brood, and the next day make the nuclei by taking the frames to their several hives, giving each a frame of honey. In this way I rarely, if ever, had a nuclei "go back on me," and have so framed the most of my nuclei till the present season. This season I have adopted a new plan which pleases me so well I will give it to the readers of the BEE JOURNAL, so they can share in my pleasure. Seeing a note in some convention report, of how a party had a queen nursery made so he could hang a frame of queen-cells in it, and then hang the nursery in a full colony of bees in the place of a frame of brood, I jotted down in my reference book (see former article on "How to use our bee journals"), under the appropriate date, "Try forming nuclei in that way," giving page and bee journal where it was to be found.

When the time arrived I made a cage of wire cloth, which would hang in the hive, and large enough so that one frame would hang inside of the cage. I now got a frame of hatching brood, brushed all the bees off from it, hung it in a hive having a full colony of bees, and left it six days, when I had the cage pretty well filled with bees, and more hatching all the while. I now took it to a hive where I wished a nucleus to stand, took the frame out of the cage, placed a frame of honey by the side of it in the hive, placed the cage in empty side of the hive, so the bees which adhered to it could get with the rest on the combs, and I had a nucleus so formed that none of the bees could go back, for they had never had a flight. I was also independent of the weather, for a nucleus could be thus formed during quite cool days and nights.

Another thing which pleased me still more: The next time I tried I inserted in the frame of brood, before placing it in the cage, a queen-cell nearly ready to hatch. As this queen-cell hatched in a day or so, I had a queen 5 days old in my cage when I took it to my nucleus hive. In a day or two she took her wedding flight, and I had a laying queen 5 days after I formed my nucleus, thus making a great gain of time. I have written this in a hurry, and if all is not sufficiently plain, I will describe it

further. All will readily see the advantage of the plan.

Borodino, N. Y.

For the American Bee Journal.

A Few Wrinkles From

J. O. SHEARMAN.

On page 302, it is stated that the queen "utters shrill notes of anger." Allow me to state how it is done; perhaps it is not generally known. The queen makes the noise termed "piping" with her wings. I have repeatedly seen them do it, and shown it to other bee-keepers. The motion is much the same as that of a cricket when chirping (so called). I did not suppose any bee had a voice, in fact, how could they shout so loud with their proboscis? Because—elephants do? But elephants *have* to shout through their trunk or keep still, as they have no wings to vibrate.

Wrinkle 2. As so much is said about introducing, I will say that I always liberate a choice queen as late in the evening as I can see to do it, unless the conditions are all favorable. A queen can be quietly dropped into a prepared colony with hardly any risk, if put in so late that the bees cannot see to fly, and so quietly as not to stir them up. I used to do it by a round wire cage, with a plug at each end, and a string tied to each plug, and then ends of string brought out from under the quilt-cover, then leave the wood cover off the hive and pull the strings gently till something (the plug) separated. It would be done so quietly and late that "no one knew it but me." Another point is, the queen will not crawl out of the hive in the dark, as sometimes happens in mid-day. The queen is to blame for nearly one-third of the failures in introducing, provided, of course, the colony has no queen cells.

Now honey is coming with a rush, and it may be done almost any way, and the quicker the better, to save time.

Wrinkle 3. Can a queen breed two kinds of drones at the same time? or would it be called an indication that there might be two queens in a hive, to see drones like pure Italians, and pure blacks, living together by the hundreds? How is that Mr. Heddon? Please answer through the Weekly.

To explain my case—I have a very strong colony, put up last year for extracting, with a full set of drone combs in the second story. I had one of those dark Italian queens, impurely mated; the colony did not swarm last year. I ran all the season for extracted honey, and did well; then, in the fall, being very busy, I was caught by the snow before all my bees were packed for winter, and, as we had much weather last fall that was too bad for brushing bees off the combs, this big one was among those unpacked, and therefore was carried into the cellar with the rest. It weighed over 100 lbs., possibly 150 or more. They wintered tip-top—went to breeding early, and kept it up, as they had plenty of backing. They filled the

brood chamber, then went for the drone combs, and filled them all but two (or else emptied them, which?) any way, they weighed much less. Then I interfered, as we had a little spell of mild weather (this was about fruit bloom time). I took away all the drone combs, put them in a hive, gave them one that had a little brood in (worker brood), and a ripe queen cell, and started in for a drone swarm as an experiment. The queen came out all right, but took longer to fertilize than usual and did not lay much, but this may have been owing to the bad spells of weather we had at that time. Then I gave them a frame of brood, but, as they did not flourish, last week I took away all the drone combs, put the queen in a new hive on the old stand, moved the drone swarm away, and killed 1670 by count, besides what few I would waylay by cutting one and kicking another when down. About half or more were the yellowest drones I ever saw, and the rest as near like black drones as I know how to make them. Now, did one queen furnish the brood for all those drones, or have help? or did they merely run out of stripes for them? Mind, the drones are not all dead yet, only thinned out some, and it was not a very good day for drones either.

How many drones will a swarm have? Owing to circumstances? The Text books say 200 to 300.

I once put a drone comb in an Italian colony, to raise some on purpose, and when I had done with them, I killed 1900.

Wrinkle 4. Noticing Mr. Heddon's indicator on page 301, also so much talk last winter about little shates, moves me to mention my method of keeping track of what is going on, which I call signals. I use two or three little sticks to tell most of what I want to know in regard to the condition of my bees in the working season. For instance: 1st division, a stick laid on the front part of a hive has reference to the bees, while on the back part refers to honey or surplus arrangements.

2nd. A stick laid lengthwise, or with the frames means all right, or in working order, or it has been attended to; while if it is laid diagonally, indicates something doubtful, or in *statu quo* for the present only, but will need to be looked at again some time.

3d. Anything laid crosswise, maybe it needs something done, while two sticks laid crossing each other show that part of the hive needs looking after urgently, etc.

The larger the object in case of an urgent signal, the more urgent is the call. It will be seen that much can be said with a little movement of one stick or two, and you could easily see them as far as you can get a fair view of the cover to the hive. If I have a signal to show that something needs to be done with any hive, I can trust to my memory for the rest, and so keep posted as to the needs and condition of my bees (100 colonies or more), without writing much, and it is quicker.

The most I write down is the pedigree of queens (and that by number),

and anything in regard to nuclei in rearing queens, etc., though most of that can be shown by a stick. I use entrance blocks mostly.

On page 300 the sense was perverted by putting a period at profit, where there should be no pause (4th line from the bottom of the page).

New Richmond, Mich.

Prairie Farmer.

Hiving Bees—Clipping Bees' Wings.

MRS. L. HARRISON.

A lady called on me yesterday who had caught a runaway swarm of bees and hived them in a nail-keg. They had been in it four days and she had procured a Langstroth hive, and wanted to put them in it. A friend, "who knew all about bees," told her to jar them down in front of it. Had she done so, their nice white tender comb, that they had built, would have broken, and might have killed the queen in falling. A better way would be to alarm the bees with smoke, invert the keg, and place another over it, and rap on it with a stick. The bees will crawl up into the empty keg, and cluster in about 20 minutes. The bees are then out of the way, and the comb could be taken out, and fastened into frames with little splints. While this is being done, the driven swarm should be placed where the old one stood so that the bees returning from the fields will unite with them. A warm part of the day should be chosen to do the work, as many bees will then be absent in the fields and out of the way. As soon as the comb is transferred to the frames, it should be put into the hive, and placed where the keg stood, and the bees jarred out in front of it. If the bees do not incline to enter it, they should be driven with smoke. If honey is abundant, they will soon be at work repairing the damage, and bringing in honey as though nothing had happened. An expert transfers without driving, but a novice had better have them out of the way.

Bees are full of antics this season; they ascertain what time their neighbors are going to *flit*, and join company. They are not always in good humor, and when one colony clusters on a limb, they fight another joining them. It is only a pleasant pastime to have one colony clustered alone, but when several unite, it is a pandemonium. If the queens can be caught and caged, order may be restored, but this can be seldom done, as it is no easy task to discover a queen among so many thousands moving constantly. If these united colonies are hived together, only one queen will be retained; the others will be destroyed. Sometimes they will issue again, and cluster separately, to the delight of their owner, but oftener enter other hives, raise the mischief generally, and many will be destroyed.

This week one of these erratic colonies issued, after being hived a couple of days. We saw them, and fortu-

nately caught her majesty before she took wing, and pinned her to a comb in a tin cover with a wire gauze top, where she is now, much to my satisfaction. A comb of unsealed brood was also given this colony to nurse and rear, so that they may forget their foolishness, stay at home, rear children, and mind the house. As soon as this colony missed their queen, they returned in search of her, entered the hive, and finding her, set up a joyful hum.

Many apiarists practice clipping the queen's wing, so that when the colony issues they will return, as she cannot accompany them. When they swarm she crawls out, and can be picked up, placed in a new hive, and if the old one is removed, and the new one put in its place, the bees return, enter it, and, finding their queen, remain. It can now be removed to the stand it is to occupy, and the old one restored to its former place. Some persons, ignorant of the habits of the honey-bee, clip unfertile queens; this ruins them, as they cannot fly out to meet the drone.

The first swarm is accompanied by the old queen—which is fertile—all after swarms have unfertile queens, and if they are lost on their "bridal tour," the colony will dwindle away, unless supplied with another, or the means to raise one, as there are no eggs in the hive. The loss of the queen may be known at first by their mournful hum, running out and in of the hive, and touching the antennae of their fellows. In a day or so they appear listless and idle, but if a queen, or a queen-cell, eggs or larvae are given them, all be activity and life.

A Review and a Reply.

JAMES HEDDON.

I am much in sympathy with the individualism expressed in Mr. W. H. Stewart's article on the standard frame, on page 332 of the current volume.

As one of the advocates of the standard frame, I want to say that I favor the adoption of a standard, as near as possible and practical. I believe the Langstroth frame to be the best in use, all things considered. I may be in error; however that may be, I am forced to express my honest opinion, if I express any. Now, I would not make a law to compel any man to change one hive. That would be wrong. I will, however, urge all who are beginning, or who can change without too much sacrifice, to do so. Just suppose for the sake of the argument, that the Langstroth frame is as good as any, and no better. The time has already arrived when it will pay to change quite a number of hives, or if you have 10 or 20 American hives, to adopt the Langstroth hive for all future increase, and close out the Americans as time and circumstances make it practical. I should do this if I had 50 of them on hand; yes, even 100. Now if I thought the American

hive the best, *enough* best to pay for my paying extra prices for irregular supplies. I would use it if I was the only man that did, and all the world clamored against me. I honor him who has the grandeur to entertain convictions of his own, and the bravery to announce them on all proper occasions. I am the last one who wishes to force him to sacrifice his manhood by renouncing his convictions, either by the finger of scorn or withdrawal of patronage. I like Mr. Stewart's spirit, but I fear he has over-estimated the call to join the standard frame army.

A CORRECTION.

In reply to Mr. Schrock, on page 336. I wish to correct an error made by you, or I, Mr. Editor, and that is: "If I go to a colony of any kind or size, at any time, and remove the queen, they construct no such queen cells as the same colony will when they do it of their own accord, with the queen in the hive." The italics shows the change. I presume, in my hurry, I made the mistake.

The pending "honey glut," that which I have so long expected, it seems, is well-nigh upon us. It is with much interest that I await and watch the results which this state of things will have upon the tweedle-dee element of our pursuit.

Dowagiac, Mich., July 4, 1883.

For the American Bee Journal.

The Best Size for Brood Frames.

DR. G. L. TINKER.

All things considered, what is the best size for brood frames? We are told time and again that the standard Langstroth frame is. It is argued chiefly that it is the best, because so many use it. As practical, valid reasons do not appear to be forth coming why it is the best, we are inclined to the belief that much of the high-sounding praise bestowed upon it is either vague or intended for buncombe.

The truth is, that so many bee-keepers use the Langstroth frame because it was the size recommended by the Rev. Langstroth, and first introduced under his patent. Thousands of his original hives were disseminated over the country before any other size of movable frame hives were extensively known. And many continue to use his frame not because it is thought to have special advantages over any other size, but out of respect to one of the most noted bee-keepers of this country, past or present, which is a reason of some merit. Again, it has had extensive and systematic advertising, and it is due, unquestionably, to the above causes that it is more widely and extensively disseminated in this country than any other size of frame.

It is well known that the adoption of the Langstroth frame in Europe has made no great headway. If it had the singular merit of being the best frame for any and all purposes of bee-keepers, as is claimed so confidently, we can well think that our

European friends would not be slow to adopt it as a standard.

THE SHALLOW FRAME.

What were the inducements that led the Rev. Langstroth to adopt a shallow frame? It will be remembered that there was a time when it was thought that a honey-board having auger holes through it for the bees to pass up into two or more large boxes, was the right thing. Very well, it did not take so good an observer as the Rev. Langstroth very long to ascertain that even black bees would not travel more than half a mile through shallow chambers and auger holes in order to get into the boxes and expect them to store surplus to advantage. He, therefore, made the shallow frame, and set the boxes down as near to the brood as possible. And he found that a frame about 9 inches deep gave the best results. As to this one point, I do not believe there is a bee-keeper in the country who will dispute the correctness of his finding where a honey-board is used, and this principle will hold true in any case where the shallow chamber above the brood frames is allowed, honey-board or no honey-board.

So my first argument against the Langstroth frame is to score one for it. Is not that fair? But an unprejudiced consideration of the points that go to make the best frame demands it. My objection, therefore, to the standard Langstroth frame is in the length, and I opine that the sole reason that it was made so long was to accommodate just two more 6-pound boxes at the rear of the hive, as the modern system of tiering up section boxes was as yet unthought of, and without which sufficient surplus capacity on the top of the hive could not be had. There is, however, just one advantage in the length, but this is slight, and more than counterbalanced by a number of serious disadvantages.

BEST WINTER FRAME.

It will be remembered that in the spring of 1881, after the hard winter, conceiving that there might be some very great advantage in the size of brood frames, either in depth or length, or both, for safe wintering, the writer undertook a searching investigation to that end, and collected much valuable information on the subject. This investigation developed the fact that there are two points of advantage in the size of frames for wintering; an advantage in the length as well as in the depth; that the advantages of the American and Gallup size of frames in depth over the Langstroth frame were offset by the greater length of the latter. Consequently the result in wintering on these frames, other things being equal, was about the same.

As a matter of fact, the Shuck and Quinby size of frames are the best to winter bees upon, and both of these are longer and deeper than the Langstroth. The reason that the editor of the BEE JOURNAL was able to give a better showing for the Langstroth

frame in his general report than I gave in mine on the result of wintering 10,000 colonies of bees in the northern States, was due to the fact stated by Mr. Geo. W. Baker, in the June number of the *American Bee-Keeper*, viz.: "The report being taken from all over the United States." That is accounted for as follows: There are probably ten Langstroth hives in the South to one of all other kinds of movable frame hives. As bees winter the best in the South, it can be readily seen how reports from Virginia, West Virginia, Kentucky, Tennessee and Arkansas should materially alter the footings of the reports made here at the North, if included with them. Recognizing early this liability to error, it was stated expressly in my report that it was from the northern States only, and the result, as is well known, was a showing against the Langstroth frame, squarely and honestly made, and which, in my opinion, approximated the result here at the North very closely.

The difference between our reports not being very great, caused me to give little attention to it at the time for a reason given in my report (see page 180, BEE JOURNAL for 1881), viz.: "As to the best winter hive, the tables do not show such a great difference between the standard hives as between the different modes of wintering." My conclusion was, that the difference in the size of frames, as far as wintering is concerned (especially in protected hives), is not worth contending about.

I have been thus explicit in the review of that investigation, to set at rest, if possible, the idea of so many bee-keepers that the shape of the brood frame is any considerable factor of the problem of successful wintering. Hence, in footing up the points of the best frame, I shall not take into consideration the fact that a long and deep frame is a little the best to winter bees upon, since, if properly protected and ventilated, bees will winter about as well in one kind of hive as another, and if I remember aright, the editor of the BEE JOURNAL has expressed himself to about the same effect.

The points that can be sustained against the standard Langstroth frame are as follows:

1. It is a great disadvantage over a shorter frame in building up weak colonies in the early spring, since the bees will cluster in the front end of the hive, leaving the whole back end vacant, so that the heat of the colony cannot be economized by a division-board.

2. The top-bar is 5 inches longer than necessary to set on a rack containing 28 one-pound or 21 two-pound sections. I use racks of these sizes on 9 Gallup frames with fair success, and the top-bar of the frame is only 13 inches long.

3. It cannot well be made so that the top-bar will not sag in the centre. Nor can it be wired by any process that I have seen, so as to hold the top-bars true and in line with each other. The result is, that in producing comb

honey the top-bars are always more or less waxed up, and are troublesome to clean off so as to get the frames out of the hive. With me this has been the most serious objection.

4. The small sections cannot be used to advantage on a long sagging frame. There are those who will likely be pleased to learn this, but let me say right here, that there is a future for the half-pound section that will astonish some of the slow-going wise-acres.

5. It is, for many persons, too heavy to handle with ease and rapidity.

6. The bees do not, as a rule, build so straight and perfect combs in a large frame as a small one.

The above will, it is hoped, be enough to satisfy those who have been going into ecstasies over the Langstroth frame, that it is not a perfect frame, nor yet the *very best*. I have the Gallup frame in use in the most of my hives, but am free to admit that it is about 2 inches too short for an exclusive top-storing hive. It, however, gives satisfaction, is easily handled, and the combs are generally built true, while the top-bar is seldom found sagged when made of only 5-16 inch stuff one inch wide.

I find that the top-bar of the frame may be 15 inches long, and not sag to give trouble, while it will afford ample room on the top for any kind of section. My judgment, therefore, is that a frame 9x13 inches inside measure, or thereabouts, is about right for all practical purposes, and if ten of them are used in a hive, it combines more favorable points than any other size of frame.

New Philadelphia, O.

For the American Bee Journal.

Adopting a Standard Frame.

A. J. SCHROCK.

As this subject is again being discussed, let us consider what size would give the best satisfaction. 1. In regard to changing those already in use. 2. In making new ones. As most of the frames now in use are the Langstroth frame, we should adopt a frame similar to that. Some have preferred a frame 10x15 inches, inside measure. I object to this size, because those frames that are shallower than 10 inches, could not be used to advantage. 3. The same dies could not be used in making foundation, etc. The only objection I have to the Langstroth frame is that it is too long, and I am inclined to think a frame several inches shorter would give better satisfaction. For this reason I think we should adopt a frame 9½x15 inches, inside measure. As this size is just 2 inches shorter than the Langstroth frame, that frame and hive could be used simply by cutting off 2 inches from one end. The one-pound sections could be used, if need be, or three one-pound sections and 2 half-pound sections could be used end to end. Six sections 4½x5 inches will fill a broad frame, while 8 4¼x4¼ inches are required to fill the Langstroth frame. A section 4½x5 inches

is a more convenient size than any smaller size. They will hold a little over a pound, and when well-filled, 1¼ pounds. If a customer asks for about 1 pound of honey, he will get a little more; thus increasing the amount sold, or they can be made to hold just 1 pound by making the sections narrower. It has also several advantages over the Langstroth frame; being 2 inches shorter, it is not as liable to sag; not as many wires are required when wiring the frames. It needs no centre brace to prevent sagging. As 10 Langstroth frames are too many for one hive, 10 frames 9½x15 would be just enough. But as each one has a mind of his own, I fear our talk will not amount to much, but if once adopted, it would certainly be a great convenience.

Goshen, Ind., June 25, 1883.

Putnam County, Ind., Convention.

Mr. F. L. Dougherty gives the following report of this meeting in the *Indiana Farmer*:

We had the pleasure of meeting with the Putnam County Bee-Keepers' Association at their regular monthly meeting, on the third Saturday in June.

The meeting was called to order by President A. O. White, of Greencastle. After some preliminary work pertaining to the regular rules of the Society, the secretary, Mr. W. B. Mann, of Fillmore, read a lengthy article, which was calculated to bring on a general discussion of the many interesting points connected with the bee-keeping interest. He dwelt at some length on the mortality of bees, claiming as a whole, bees were no more liable to disease or death than anything else which the farmer might attempt to grow in connection with the mixed farming so extensively practiced at the present day. While as he said the past two or three seasons had been below the average in honey production in the central part of Indiana, the yield for the present season, to those who had not forsaken the business, would be sufficiently large to cover the entire loss of the three past seasons. The superiority of Italian bees over the black was also claimed, and the reasons why. Breeding from the best colonies, clipping the wings of the queen, its advantages and disadvantages, etc. Pending the discussion of the several questions the Society adjourned for the noon hour. At the call after dinner, the meeting was opened vigorously in the form of a question box, covering almost the entire ground, the morning questions included, all being disposed of in the regular order, calling out the different experiences of the members of the Society. The almost extinct black native bees still had friends in the Society. One thing we noticed, and to which we should like to call the special attention of the members of the Society; the lack of uniformity in hives. This is one of the most important subjects to which the Society can give its attention. Not the Langstroth hive, be-

cause we think it the best now made, but to a perfect hive of some form, and then all exactly alike. There were members present who did not know what form of hive they were using. Did not know the exact size of the frame. Could not tell what size of section would best fit the hive, etc. All of which should be understood at the start, to be able to take advantage of the instinct of the bees, to realize the best results.

For the American Bee Journal.

Controlling Drone Production.

JAMES F. WOOD.

Doubtless many readers of the BEE JOURNAL believe that if their hives were all worker combs, they could have drones reared just where they desired, by giving the colonies drone comb. This, however, is a mistake, at least I never saw a strong colony but would rear drones; either they would tear down worker comb, and in its place substitute drone comb, or rear drones in worker cells, or around the edge of the comb. I first discovered this fact last season. Fifteen colonies of hybrids were brought into a yard of Italians, in which queen-rearing was carried on extensively; as these colonies had their combs all built on wired foundation, of course I thought no drones would be reared. True, none were reared until the hives became crowded with bees, when drones were then tucked in throughout the hive, and it became necessary to cut off their heads every few days. As we did this, we noticed more capped drones each successive time, until they so increased that five or six hundred were in each hive. This is exactly our experience this season with upwards of 50 colonies, built on wired foundation, with the exception that we let the drones hatch. If any think I am in error, I invite them to examine some of their strongest colonies, or a colony that has just cast a swarm, and they will not long be in doubt. Of course I mean one that had no drone comb in the spring.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich

Building Comb in Wired Frames.

In the *Kansas Bee-Keeper* for June, some one says I am mistaken in regard to the impracticability of wiring frames for bees to build new combs in, without the use of foundation. He says the force of circumstances caused him to try it, and it worked perfectly, the bees building the combs centrally in the frames with the wires in the septum. This settles the matter with him, of course. I do not remember of having read any one else's experience in the matter. My own experience, that which prompted my answer, is this: On several occasions the foundation has fallen down through neglect of properly securing it, when we were putting it on by hand. Not discovering the accident, the bees went on to build their combs, and, notwithstanding the combs were built between other sheets of foundation which remained intact, in no instance did they build the comb with the septum on the wires, but the wire usually run right through the cells, and had to be withdrawn. This is all I know about the matter. Further experiments will be required to settle the matter in my mind, and probably in the minds of bee-keepers generally.

What Ailed the Bees?

I send you by this mail pieces of comb taken from two colonies which have two or three cards affected each. I wish you to answer through the *BEE JOURNAL* what ails them, and what is the best plan to pursue with them. The cells of these cards are filled with honey as fast as empty, instead of eggs; and upon opening them, some cells will be empty or the contents dried down.

F. A. BURRILL.

Cuba, N. Y., June 29, 1883.

The comb is received. My experience with foul brood is limited to cautiously looking at, and smelling of one comb brought to our Michigan State Convention, at Battle Creek. I have always been so much afraid of it, however, that I have taken pains to "read up" that I might detect it at once, if it ever occurred in my apiary. I have burned your comb and box. To the best of my judgment, I feel sure that there is no foul brood of any type about your comb. I think the cause of the phenomenon you mention, is a temporary one, caused by

some change in the conditions of your hive. It looks more like "chilling." I could not decide satisfactorily to myself, unless I could have more light regarding all the conditions, and perhaps not then. If it continues, with no seeming cause—to change the queen would be my advice.

Fastening Wired Foundation.

Having been unsuccessful in fastening the wired foundation in frames, please give, in the *BEE JOURNAL*, the best method of fastening it.

Racine, Wis.

F. A. GIBSON.

ANSWER.—Nearly all feel the necessity of some device to hold the foundation true in the centre of the frame, to a certainty, and I think I am safe in saying that all of the devices known to the public at present, none equals the use of tinned wire, woven through the frames. Proceed as follows: When your frame material is out, and before nailed up, punch holes (centrally) through the top and bottom bars about 2 inches apart, and have the outside holes not further from the end bar than $\frac{1}{2}$ or $\frac{3}{4}$ of an inch. For hand pressing, as I am now describing, use No. 30 tinned wire. Now sew the frame, beginning in the middle and sewing each way with each end. To fasten the ends I use a small tack, or the nails that nail the bottom bar may be left a little out. Be careful not to bow the bottom bar by drawing the wire too tight. Diagonal wires may be put on, but I do not use them, as I find no need for them. To use them, fasten one end to the nail head, and then go down through the first hole, and through the one nearest the centre of the other bar, then up through the other centre hole, and fasten this end the same as the first. Now the frame is wired. Next make a lap-board larger each way than your frame is the longest way. Now cut from $\frac{1}{2}$ inch lumber a board that is $\frac{1}{4}$ inch smaller each way than the inside measure of your frame. Nail this board securely to the $\frac{3}{8}$ lap-board, and let the grains run cross-ways of each other. This will prevent warping. With a sponge or rag wet the thin board or form. Have already cut, some sheets of foundation $\frac{1}{8}$ less in size than your frame measures inside. Turn up about 3-16 of one edge, and (have the wax sheet warm) with a stiff, broad putty knife, or chisel, mash the turned-up portion to the top-bar (which should not be rough), so that the sheet will hang centrally in the

frame. We have a rest fixed for the frame, on our work bench, to hold it while we do the mashing. Next lay the frame and foundation (foundation down) on the lap-board and over the form, and while the sheet is plastic.

Stroke the wires with the edge point of your jack knife with a drawing motion, and while this little cut will do the foundation no harm, if struck every $\frac{1}{2}$ inch or so, the wire will be thus embedded into the centre of the foundation in a practical manner, and very quickly too, and so that it will stay, holding the sheet in perfect position while the bees make it into comb, which they do. Given foundation in about 24 to 48 hours. There is no objection to these wires at all. Honey, pollen and brood do as well in the wired cells as any.

Is It not Contradictory?

Will Mr. Heddon please tell us what he means by saying, on page 314, of the *BEE JOURNAL*, that "less colonies are required to gather the honey of a given area, when they are working for extracted honey than when working for comb honey?" In the next paragraph he says: "He can get but little more extracted than comb honey." Here is a seeming inconsistency. Why should it require a much less number of colonies to a given area for extracted than for comb, if a colony can gather only a "little more" extracted than comb honey?

JOS. G. STEER.

Barnesville, O., June 25, 1883.

ANSWER.—What I meant by saying that less bees were required to gather a field when running for extracted honey rather than for comb honey, I will explain as follows: When running for comb honey, a considerable number of bees are kept at home in building comb, capping over, and ripening the honey to an extent beyond that which bee-keepers generally allow the honey to be ripened and capped when running for extracted honey. Another thing, you will notice most bee-keepers get nearly twice as many pounds of extracted as of comb honey, though this state of things ought not to be, still it is, as a rule, and I made my answer somewhat fitting to things as they are. Of course we weigh it up, sections, foundation and all, with our pounds of comb honey. Now, the difference in the number of bees required to exhaust a field, by one running for extracted honey, would depend entirely upon the skill of the producer. At all events you will see there must be a difference any way. When bee-keepers learn to estimate

this business in the light of how many fields they had better occupy, and how much capital and labor it will require to exhaust the field, instead of how much surplus honey a colony of bees can gather, we shall be getting down to business and to the solid facts of apiculture.

Syrian Bees Crossed with Italians.

Please explain more fully what has already been explained (perhaps plain enough for some), but I do not fully understand it. On page 314, of the Weekly BEE JOURNAL of the present year, there is a question asked, "What objection would there be to crossing the Holy Land bees with the pure Italians, etc.?" The answer is, "They have not the valuable qualities possessed by the Italians," but the brown Germans have. I think I have read that what is commonly called the black bee, is a German bee (of course they are a brown bee). Am I right in that? Is that the bee you mean? Do you consider the leather-colored Italians better than the bright ones, and the crossing you speak of better still, best of all? EDWARD MOORE.

Barrie, Ont., June 27, 1883.

ANSWER.—My answer regarding crossing Syrian with Italian bees, is not worded just as I meant to have it. I think it should read: "They have not the valuable qualities *not* possessed by the Italians, and which the honey-producer so much needs, but which the brown Germans have." The idea I meant to carry was this: that the excellent qualification possessed in such an exalted degree by the brown German bees, namely, rapid and perfect comb building, and white capping of the honey, is not, if I am properly informed, possessed by the Syrians. I have demonstrated that hybrids produced by crossing Germans and Italians *may be* as amiable as any bees in the world, but I doubt if such can be realized by crossing the Italian and Syrians. Regarding the two varieties of German bees, let it be understood, the brown bee is by far the most common, and is the bee possessed to a greater or less extent by those who keep "black bees." The little black bee is smaller and a more shiney black, and is a poor honey gatherer, exceedingly irascible, and when crossed with the Italian, especially the bright yellow Italian, gives us the naughty hybrid. Many black-bee apiaries (most, in fact) are made up of bees which seem to be a mixture of the brown and black Germans. Those who propose to breed crosses between the Italians and Germans, should see to it that they start with the brown Ger-

man bee, entirely free from this little black blood, and straight leather-colored Italians.

SELECTIONS FROM OUR LETTER BOX

Discouraging Weather in New York.

When I last wrote we had been having three days of fair weather, so the bees were getting a little more honey than they consumed. We had one more fine day, then it commenced to rain again, and it has now rained three days. Farmers are nearly discouraged. The ground had got dry enough the four fair days, so they had just begun to cultivate their crops, and now it is soaked and water stands on the driest ground. Clover is likely to pass by without giving any surplus honey. G. M. DOOLITTLE.

Borodino, N. Y., June 28, 1883.

An Insect—Leaf Cutter.

I enclose an insect, which I found working in great numbers with my bees, upon the Mammoth Russian Sunflower. Upon examination under a common microscope, I found all of the main points visible on a bee, but on a coarser scale; the head, wings and legs seemed to be out of all proportion to the rest of the body. They possess stings which they know how to use. I watched several of them for some time, but only saw them gathering pollen, which they did in a similar manner to the bee. Please inform me through the BEE JOURNAL. 1. Their name. 2. How and where they build their nests. 3. Whether they store away honey or not. Bees are doing very poorly. M. T. HEWES.

False River, La., June 17, 1883.

[The pretty little bee is a leaf cutter, *Megachile brevis*. Unlike the hive bee and several other species, this one does not live in colonies, but each female makes and provides for her own nest. The latter is made of bits of leaves cut in circular shape, and wonderfully regular and workmanlike. The nest is placed in some sheltered position, under balconies of houses, rails of fences, limbs of trees, etc. No honey is stored, the larvæ being fed on pollen. Set some of the young folks to watching the curious operations and interesting habits of this busy worker. Look for circular cuts from leaves, especially of rose bushes.—T. J. BURRILL, Champaign, Ill.]

Honey Gathering in Connecticut.

My 90 colonies and 40 nuclei keep me busy. The first swarms here were on May 18, about 10 days earlier than usual. White and red clover bloom is abundant; I never before saw so

much. Bees are working strongly on both. There is a heavy basswood and sumac budding. Honey is coming in rapidly. The losses of the past winter are more than repaired, and swarms are issuing daily. Many of the early swarms are casting swarms and working in boxes too.

H. L. JEFFREY.

Washington Depot, Ct., June 30, 1883.

Rolling in the Honey.

Times have changed greatly since the 19th. We have had no rain for 12 days. My bees are just rolling in the honey, and in spite of all the sections one can pile on, they will swarm.

S. L. VAIL.

Coal Creek, Iowa, June 30, 1883.

Honey Crop a Failure in Texas.

Our honey crop, so far, is a failure. I have had bees in such condition as to surplus but once in 4 years. It will not make half a crop this season. Horsement is in bloom, and there is plenty of it, but the weather has been so unfavorable that the flowers secrete no nectar. Every hive is full of bees, but we have no swarms (not over 5 per cent.) and no honey.

WM. R. HOWARD.

Kingston, Tex., June 29, 1883.

A Bee Killer—and a Flower.

I enclose an insect upon which I should be glad to have you give me some information. I find a great many of them, late in the evening, in my apiary, and have just discovered that they catch bees. This insect, as you see, has one in its mouth, partly eaten, and it held another in its claws, when I killed it. I also send you a bunch of flowers, with a twig from a bush that grows in my yard. The bees swarm on it all day. My bees have not swarmed much, but they have gathered a great deal of honey, filling up the combs every two or three days since April 15. It is all that I can do to take the honey from them. All the bee-keepers in this vicinity report a bountiful harvest.

W. G. MCLENDON.

Lake Village, Ark., June 20, 1883.

[The bee-killer is what is very commonly called a dragon fly, sometimes darned needle, mosquito hawk or snake feeder. The scientific name is *Eskna heros*. This is by no means the first time the large insect has been known to catch bees, though they more often capture other, and especially smaller prey. They are appropriately called mosquito hawks. In the larval or young condition the wingless, strange looking things are called water tigers. They live in the water and catch living prey in their powerful sharp-pointed jaws, which they can thrust out, by a peculiar appendage, with the rapidity and effectiveness of a steel trap. They live about a year in the water, then transform into the winged insect

and continue their predaceous habits in the air. Probably they do no very serious damage to the bee colonies, yet in special cases the loss might be considerable. I do not know any effective preventive.

The shrub is known to botanists as *Myginda latifolia*, a native of our Southern States. I am not acquainted with any common name, neither do I know anything of its nectar-producing value—probably not great.—T. J. BURRILL, Champaign, Ill.]

White Clover Thicker than Ever.

I had 7 colonies of bees in the spring; most of them in common hives; but reading the BEE JOURNAL induced me to transfer 5 of them to frame hives. I have been successful, and have now 15 colonies. The white clover is thicker than ever known here. HENRY ERBRODT.

La Harpe, Ill., June 29, 1883.

Not Snow, but Clover.

The whole earth hereabouts is white with bloom, and our bees are fairly bursting with their loads of honey, as they return from the fields; and such honey, so thick, it almost stands alone, and the combs are as "white as the driven snow." I saw Prof. Hibbard at his South Bend apiary, the other day, with honey fairly dripping from his garments, and a glow of gladness all over his face. Tell Mr. Heddon to roll up his sleeves, and Mr. Doolittle to take off his overcoat. Tell all the boys to get out their honey pots, for this is the great honey year of the century. Let the horse-mint State, and the Pacific Slope take back seats, and the Buckeye State will come to the front, for it is "our turn to be sweet." This sounds, I know, a good deal like buncombe, but it is nevertheless solid gold, for we are just reveling in it.

J. W. BAYARD.

Athens, O., June 28 1883.

Magnificent Clover Bloom.

It has been a very showery season, so far. We have a magnificent bloom of clover, but bees scarcely gathering a living, to date. At present it is clear, with northwest winds, which looks favorable for honey flow.

H. S. SEE.

Geneva, Pa., June 30, 1883.

My Visit to Arkansas.

I returned from Arkansas one week ago, and found my bees working nicely on white clover and the last of red raspberries. My wife had managed them very nicely; to avoid swarming she had tiered them up, and to-day the upper stories are full, and for the first time in my life, I have raised the second story and placed another under it. I have plenty of dry combs for the purpose. The honey in the upper stories is too thin to extract. While in Arkansas I met Dr. W. W. Hipolite, of De Vall's Bluff (the first wide-awake bee man I met

in the State). He is very genial, but for the last year or two has had too much to do to give his personal attention to the bees; he has a son, Walter H., who is looking after the bees. I am quite taken up with the country round about De Valls Bluff, so much, so, that I think of going there to live, if all goes well. When I left them, on June 17, their bees had all done swarming, and they had commenced taking off capped honey. They have no fears of winter; their greatest difficulty is to keep swarming down to what they can handle. I have had my first swarm to-day; others will issue to-morrow, if the weather will permit. Mr. Ross has had 25 or 30 new colonies. Tiering up has prevented ours. O. R. GOODNO.

Carson City, Mich., July 1, 1883.

Honey Very Thick.

The honey season is very satisfactory here. The quality of the honey is the finest that one could imagine—so thick that it "piles" when running from the extractors. The comb honey in sections is exquisite in every respect. G. W. DEMAREE.

Christiansburg, Ky., June 29, 1883.

Recovered from Spring Dwindling.

My bees have been affected with spring dwindling, and have recovered very slowly; they are just beginning to swarm, while some are storing little honey. White clover is very abundant now. The spring has been too cold. T. N. MARQUIS.

Woodland, Ill., June 30, 1883.

Honey from Dog Fennel.

Mr. Newman, is the honey from dog fennel poisonous? I am aware that the seed will kill ducks; and it is reported to kill chickens. The honey from it is very bitter, disgustingly so, and if you like fun at others' expense, just coax them to taste some of the honey. One dose is sufficient. Two years ago, by using two extractors, I got two 5-gallon cans of the bitter honey, thinking to feed it to bees, if necessary, but had no occasion to, as they did not need it. The following season, in fruit time, in looking over honey for putting up fruit with, and tasting the honey, there was not the slightest taste of bitterness, and honey being scarce, one of my customers insisted on taking a can of it, though at a reduced price. He afterwards spoke of it as being all used up, and found nothing unpleasant about it. We used the balance in preserving our fruit. It was dark, but that really was no objection for home use. The fruit turned out well; some kept over a year, and was as good as any. No one could tell that it came from dog fennel. Of course there must have been other honey with it. Since then I have cut the dog fennel. The buckeye is in bloom, and has been now for some time. Why I wish to know about the flower being poisonous, is this: I find, during the last few days, young bees coming out of the hives to die; they do not appear to be cleaned off, and are just

hatched. On opening the hives I find unsealed honey, so they do not seem to be short of stores (there is plenty sealed). The queen seems all right, and laying. The *Tione*, or bear bush, is just coming in bloom, and it may be that the honey from this does not agree with the young bees. The bees work very lively on it. The honey from it has a tart taste. I only noticed a few of the hives in that condition; the rest of them are in a normal condition. I have no disease among my bees. All the colonies are strong. I have increased from 23 in the spring to 70. All have honey enough to go through the season with. Comb honey will amount to but little with me. All I get is extracted from the brood apartment, to give the queen room, and keep down swarming. I depended on natural swarming this season, but see no advantage over dividing at the proper time; no swarms got away. Some young queens swarmed out, with full colonies. The honey crop is short, owing to continued cold rains and long spells of northerly winds, which dried up the late bloom or stopped the secretion of honey. J. D. ENAS.

Napa, Cal., June 25, 1883.

[We have never seen any honey from dog fennel, that we are aware of, and, therefore, do not know whether it is poisonous or not. If any have had honey from it, they will please report.—ED.]

A King Bird's Meal.

I send you a box by mail containing the contents taken from a king bird's crop, which I shot to-day. Please give it a microscopic examination, and see if you find worker bees or drones. I shot two, to-day, and by examining their crops, I have about concluded that they catch nothing but drones. Bees in this locality are in fine condition, and are storing surplus honey quite rapidly.

W. W. SHERWIN.

Warsaw, N. Y., July 4, 1883.

[We have examined the poor bird's meal, and find nothing but drones in it.—ED.]

Presistent Swarming.

Bees are on a big boom here. I have taken something over 5,000 pounds of honey, up to date, from 97 colonies to start with. For 12 days, when swarming was the rage, I had not a single brood frame or comb not in use, and Mr. Muth could not supply me. I was having from 6 to 12 swarms a day, and my bees in two apiaries, 1½ miles apart; had all the old queens' wings clipped. I had a black woman at the largest apiary who would catch and cage the queens when the swarms came out, and lay the cage in the portico, or in front of the hive, as many of my hives are somewhat like Mr. Heddon's, without porticos. I added sections, supers, cut out queen cells, distributed the bees around (a quart to one hive, a wash pan full to another) until I got

everything full. I kept some queens caged, just lying in the portico for a week. I am a queens' wing "clipper," henceforth. I formerly said I did not let my bees swarm. I now take it all back. Several nucleus colonies swarmed. I had to stuff them full of bees by dividing up my colonies, and they started other cells, and when the queen hatched in the cell I gave them, out they came, and in some cases, leave with a swarm, when the old mother had to stay at home. The bees are swarming now, and I must see about it.

E. DRANE.

Emenence, Ky., June 27, 1883.

Bees are Doing Well Here.

There are four times as much white clover, this year, as there has ever been in this part of the country.

HUGH MCCORMICK.

Pellsville, Ill., July 5, 1883.

Best Season for Many Years.

Bees are doing well here, this season. It is the best season that we have had for many years. There are not a great many bees in this county. Comb honey sells readily at 20 cents per pound. I am running my bees for comb honey, this season.

JOSEPH E. SHAVER—15.

North River, Va., June 29, 1883.

Too Rainy.

It has been too rainy for bees; for the last two days they are doing well, but I am afraid of more rain shortly. I have but 8,000 pounds of extracted honey up to date. I have about 600 colonies, 500 in good condition.

L. LINDSLY.

Waterloo, La., July 2, 1883.

The National Convention.

The National Bee-Keepers' Association, will hold its Annual Convention in the City Hall and Council Chamber in the city of Toronto, on Tuesday, Wednesday and Thursday, the 18th, 19th and 20th days of September, during the second week of Canada's Great Fair. All the railroads in Canada will issue tickets during this week, good to return, up to Saturday night 22d, at single fare for the round trip. Special excursion rates will be arranged from various parts of the United States, of which due notice will be given. Those who intend being present may be kept posted on the latest excursion rates, etc., by addressing me, and also that I may arrange hotel accommodation. Private lodgings will, if possible, be secured for those who desire it, and every effort will be made to make everybody comfortable. A grand meeting is anticipated.

D. A. JONES, President.

The bee-keepers of Hunt County, Texas, will meet at Dr. Wm. R. Howard's apiary, on the 19th of July, for the purpose of permanently organizing a County Association.

WM. R. HOWARD.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Special Notice.—We will, hereafter, supply the Weekly BEE JOURNAL for one year, and the seventh edition of Prof. Cook's Manual of the Apiary, bound in fine cloth, for \$2.75, or the Monthly Bee Journal, and the Manual in cloth for \$1.75. As this offer will soon be withdrawn, those who desire it should send for the book at once.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price still lower, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 50 cents; per hundred, \$3.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

How to Advertise Judiciously.

This is what Robert Bonner, the New York publisher, and one of the most extensive advertisers in the country, has to say on the very interesting subject of advertising. Its application is general enough to cover the entire field:

"One of the points of good advertising, is to address the same people over and over again. For instance: Suppose you were introduced, with about 500 others, to the President, the chances are that the President would not remember you. But if you had an opportunity of seeing him again, and said, 'Mr. President, I am Charles Wolsey, of Brooklyn; Senator So-and-so did me the honor of introducing me to you,' and you did this two or three times, you would be sure to be remembered. In the same way an advertisement presented once is forgotten, while one presented over and over again makes an impression."

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Do not send coins in a letter. It is dangerous and increases the postage unnecessarily. Always send postage stamps, for fractions of a dollar, and, if you can get them—one-cent stamps; if not, any denomination of postage stamps will do.

Bingham Smoker Corner.

Large Smokers need wide shields. Bingham's have them, and springs that do not rust and break, and bellows that sparks and smoke do not enter. The Conqueror has all improvements made to date, and a 3x7 inch stove, and 5x7 inch bellows. Sent post-paid for \$1.75. Address,

BINGHAM & HETHERINGTON,
Abronia Mich.

All Excelling. — Messrs. Bingham & Hetherington, Dear Sirs:—I am now selling your Smokers almost exclusively. You are excelling yourselves in smokers all the time.

Respectfully, J. G. TAYLOR.
Austin, Texas, May 10, 1883.

Cyprians Conquered.

All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am "boss." Bingham's "Conqueror Smoker" did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham.

G. M. DOOLITTLE.
Borodino, N. Y., Aug. 15, 1882.

During the following three months, Bingham Smokers will be sent post-paid, per mail, on receipt of the following prices:

The "Doctor" (wide shield)—3 $\frac{3}{4}$ in. fire tube, \$2.00
The Conqueror (wide shield)—3 in. fire tube, 1.75
Large (wide shield)—2 $\frac{3}{4}$ in. fire tube, 1.50
Extra (wide shield)—2 in. fire tube, 1.25
Plato (narrow shield)—2 in. fire tube, 1.00
Little Wonder (narrow shield)—1 $\frac{3}{4}$ in. fire tube, .65
Bingham & Hetherington Uncapping Knife, 1.15

With thanks for lessons of encouragement, and the absence of complaining ones, we tender to our thirty-five thousand patrons our best wishes.

Very Respectfully Yours,

BINGHAM & HETHERINGTON,
Abronia, Mich., June 1, 1883.

Sample Copies of the AMERICAN BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Queens! Queens! Queens!

We are now prepared to send you by return mail the handsomest and best Queens, bred from our best honey-gathering strains of ITALIANS and ALBINOS. Purity and safe arrival guaranteed.

Tested queens.....	each.....	\$ 2.00
Warranted queens.....	each.....	1.50
" " " " " " " " " "	per doz.....	10.00
Untested " " " " " " " " " "	each.....	.30
" " " " " " " " " "	per doz.....	5.00
" " " " " " " " " "	per doz.....	9.00

If you want Queens for BUSINESS, send us an order. We are breeding from an entirely new strain this season, which bids fair to outstrip anything we have ever had before for honey. Address,

WM. W. CARY & SON, Coleraine, Mass.

The Oldest Queen Breeders in America.

VANDERVOORT FOUNDATION

110 square feet or 10 lbs. for \$7.00. In strips 5x15 to 30 inches long. Less than 10 sq. ft. to the lb. Cut any size. **H. W. GARRETT,**
COEYMAN'S HOLLOW, Albany Co., N. Y.

DUNHAM COMB FOUNDATION.

Twenty-five lbs. or less, 55c. per lb.; over 25 lbs. 52c. per lb. Extra thin and bright (10 sq. ft. to the lb.) 55c. Wax worked for 10c. per pound.
245st **F. W. HOLMES,** Coopersville, Mich.

HONEY. I wish it distinctly understood that I will not accept shipments of HONEY unless bought by me by previous correspondence.

A. H. NEWMAN, 923 W. Madison St., Chicago.

TO ADVERTISE OVER THE WHOLE COUNTRY WITH A SMALL LIST.

Advertisers desiring to reach every section of the country, without investing a very large amount of money, will find the following a good list of papers:

THE BRITISH BEE JOURNAL AND BEE-KEEPER'S ADVISER.

The BRITISH BEE JOURNAL is published monthly, and contains the best practical information for the time being, showing what to do, and when and how to do it. **Rev. H. R. PEEL, Editor.**
We send the Weekly AMERICAN BEE JOURNAL and the British Bee Journal, both for \$3.00 a year.

BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS C. NEWMAN.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most honey in its best and most attractive condition.

Appreciative Notices.

A neat and abundantly illustrated hand-book of apiculture.—American Agriculturist, N. Y.

Its chapter on marketing honey is worth many times its cost.—Citizen, Pulaski, Tenn.

Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of every beginner with bees.—News, Keltsburg, Ill.

Valuable for all who are interested in the care and management of bees.—Dem., Allegan, Mich.

Engravings are fine. Gotten up in the best style, and is cheap at the price.—Farmer, Cleveland, O.

Carefully prepared for beginners.—Farmers' Cabinet, Amherst, N. H.

A very valuable work to those engaged in bee-raising.—News, Prairie City, Iowa.

We advise all who keep bees to send for this excellent work.—Journal, Louisiana, Mo.

Carefully prepared, and of vast importance to bee-raisers.—Indianian, Chilton, Ind.

New and valuable, and embellished with 109 beautiful engravings.—Democrat, Salem, Ind.

Much practical useful information, in a cheap form.—Daily Standard, New Bedford, Mass.

The most perfect work for the price ever yet produced on the subject of bee-culture.—Anti-Monopolist, Lebanon, Mo.

A manual, containing all the newest discoveries in the management of these little workers.—Plain Dealer, St. Lawrence, N. Y.

Full of practical instruction, that no one who contemplates keeping bees can do without.—Farmers' Journal, Louisville, Ky.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.

It embraces every subject that can interest the beginner in bee-culture. The engravings perfectly illustrate the text.—Farm and Fireside, Springfield, O.

Embraces every subject of interest in the apiary, giving very thorough details of the management and manipulations necessary to make bee-keeping a success.—Farm, Longmont, Colo.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

Describes all the newest discoveries in the art, by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive shape.—Signal, Napoleon, O.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—Farmer, Lancaster, Pa.

PRICE—Bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

THOMAS C. NEWMAN,
925 W. Madison St., Chicago, Ill.

A Liberal Discount to Dealers by the Dozen or Hundred.

OLDEST BEE PAPER
IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED
IN 1861

VOL. XIX.

CHICAGO, ILL., JULY 18, 1883.

No. 29.

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Bee-Keepers' Week!

This sounds rather new and somewhat novel. Perhaps it is not yet set down in the Calendar, to be observed as a *feast*, but it is to be observed at the great Southern Exposition at Louisville, Ky., as we see by the Louisville *Courier-Journal* of July 8, a copy of which has been sent to us by Mr. W. Hamilton, of that city, with this paragraph marked:

While every day during the Exposition, from Aug. 1 until the closing, will be full of the most interesting features, certain days have been set apart for special attractions, which will be of direct interest to a large number of people. The programme on the opening day will be very elaborate; business throughout the city will be suspended during the day, and the Exposition will be opened by the President of the United States. On Tuesday, Aug. 28, begins a week to be known as Bee-Keepers' Week and Horticultural Week. Prizes will be awarded, and arrangements have been made by the Kentucky Bee Association to have many hives of many kinds of bees within the grounds.

The Kentucky apiarists are evidently at work in the right direction, and we would encourage them by every means in our power to make thorough work of it. It will be remembered that President Demaree issued a card to bee-keepers, which we published on page 339 of the *BEE JOURNAL* for July 4, and we would here call especial attention to it.

Every bee-keeper within a reasonable distance of the Exposition, whether in Kentucky, Indiana, Ohio, Illinois, Missouri, Arkansas or Tennessee, should see to it that there is a grand display of bees and honey, and

everything to be made of honey, and that the "Bee-Keepers' Week" may be made notorious by the magnitude of its exhibit. There will be plenty of honey. This is "a year of plenty," the like of which has not been known for a very long time! Let the *display* then be commensurate with the honey harvest, and it will advertise the honey crop far and wide, and cause a corresponding demand for the sweet product.

When that 150 tons of comb honey was sent to England, and was displayed like a huge mountain at the "British Agricultural Fair," with the words "AMERICAN HONEY" painted in large letters on canvas at its top, with American flags arranged in graceful folds on each of its sides, the people of that "beautiful garden spot," opened their eyes and gazed with admiration! The result was that ton after ton of it was quickly sold, and it graced the tables of Her Majesty, Queen Victoria, and aristocracy and nobility vied with each other in appropriating its sweetness, being captivated by its beauty and the magnitude of its display. It is safe to assert that now the demand for honey in Great Britain is ten fold greater than ever it was before that display was made, and year by year this demand increases. Why may not this teach us a lesson? for the Bee and Honey shows of Europe now lead us, both in their magnitude and educational results.

The year 1883 will long be remembered as America's Great Honey Year, let it also be recorded as the year of its Grand Honey Shows—the Year of Jubilee for the thousands who are being poisoned by the glucose frauds and adulterated sweets.

Let the "Bee-Keepers' Week" inaugurate a new era—when "Feasts" may be spread at hundreds of Fairs, all over the country, inviting all mankind to come and partake of God-given sweets, distilled in Nature's

own laboratory, and gathered under heaven's smiles by the "blessed bees," both for man's sustenance as food, and for its health-giving properties as medicines.

Let the invitation be given to all—Let the apiarist and exhibitor say, Come! Let him that heareth say, Come! and whosoever will, let him Come, and partake of the Honey Feast—it will create a sweet disposition, and produce a bright intellect!

The Balsams as Honey Producers.

Dr. L. Knorr, Savanna, Ga., has sent us a copy of the Rhode Island *Wochenblatt* of June 16, in which it is stated that in Germany they are very enthusiastic about a new honey-producer—the giant balsam—and that it is being cultivated extensively near Berlin for the bees to work on. The balsams of America yield honey, but we do not think they are as good honey-producers as many others. Mr. A. A. Fradenburg stated at the National Convention held in Cincinnati, Ohio, in 1880, that he had cultivated them for that purpose, and they yielded honey well.

The balsam poplar, and the variety known as "balm of gilead" yield propolis also, in good quantities.

Labors of the Bee.—As a sample of the labors of the bee in gathering honey, an exchange remarks as follows:

The bee has long been a type of the industrious worker, but there are few people who know how much labor the sweet board of the hive represents. Each head of clover contains about 60 distinct flower tubes, each of which contains a portion of sugar not exceeding the five-hundredth part of a grain. The proboscis of the bee must, therefore, be inserted into 500 clover tubes before one grain of sugar can be obtained. There are 7,000 grains in a pound, and, as honey contains three-fourths of its weight of dry sugar, each pound of honey represents 2,500,000 clover tubes sucked by bees.

Bee and Honey Show in London.

The London *Journal of Horticulture*, speaking of the annual exhibition of the Bee-Keepers' Association, to be held July 5 to 9, 1883, says:

The date of the show has been fixed nearly a month earlier than usual, in order to give those who are staying in London for the season an opportunity of visiting this interesting and instructive exhibition; no better date could have been selected. The present season has been one of the best on record for the production of early honey, the warm sunshine of the past few weeks tending to the secretion of honey, and large quantities have been gathered by the bees from the fruit blossoms, early clover, and other sources. Unusually large entries have been made in the honey classes, and the present exhibition will fully illustrate the advantages to be derived from keeping bees in an intelligent and humane manner.

The old-fashioned bee-keeper who lets his bees look after themselves until the months of August or September, and then "takes 'em up," consigning the industrious bees to the brimstone pit, will look on with wonder and astonishment at the great display of comb honey in one and two-pound sections, and extracted honey in neatly labelled glass jars, the whole of which has been secured by the third week in June, or even earlier in some districts. The exhibition will contain an interesting collection of bees confined in observatory hives. No bees will be at large; the most timid may, therefore, visit the show in perfect safety. No pains have been spared by the committee to make the proceedings of a thoroughly interesting character. Practical instruction in the art of bee-keeping will be given at intervals on each day, the modern methods of managing bees during the spring, summer, and winter months being fully explained by the most advanced bee-masters. Special addresses will be given by Frank R. Cheshire, Esq., on Saturday, July 7, on "Structure of the bee in relation to fertilization," and on Monday, July 9, on "Bees as hybridizers and fruit-producers, or the dependence of orchard crops upon bees." These addresses will be given at 4 p. m. each day.

The new two-cent rate of postage for letters goes into effect on October 1. Three-cent postage stamps will then be but little used. For all fractions of a dollar sent to us hereafter we should prefer either one-cent, or else five or ten-cent postage stamps. Do not send coins in any letter.

Do not let your numbers of the BEE JOURNAL for 1883 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

Swarms Selecting a Location.

In proof that the bees do select a place in advance, by sending out "scouts," Mr. Geo. Yeomans, Shedfield, England, gives the following in the *British Bee Journal*:

In an outhouse, hid under trees and amidst other buildings, I had a few days ago put a number of old straw skeps, one of which contained old comb. Seeing the bees visiting this house, I put the old hive with the comb near the window, and on the next day, June 8, a swarm took possession of it.

The *Grange Bulletin* says: "One of our patrons has taken 220 pounds of nice extracted honey from 6 colonies of bees in one day; and still they have all their combs returned and are refilling them with a fresh supply." This is only a small straw—but "straws show which way the wind blows."

The White County, Arkansas Fair will be held at Judsonia, Oct. 10 to 12, 1883, as we are informed by Mr. C. M. Forbes, the secretary. We hope that a good exhibition of honey will be made by the bee-keepers of that section.

Rough on Vermont.

We have sung the praises of old Vermont for many a year, but this rather disheartens us. Editor Cheever of the *New England Farmer*, has just been buying "pure Vermont maple sugar," and finds it to be chiefly glucose. We did not suppose that Chicago influences had extended so far and so rapidly. We have known Vermont farmers who put a false 2 inch birch plank bottom inside their butter tubs; one who accidentally let drop a 2 pound brook cobblestone into the firkin as the butter was being packed; of one whose "artful wicked" hired man put water in the milk can before starting for the cheese factory; of one whose "hired girl" carelessly turned over the salt box upon the butter worker; of another who forgot and skimmed the milk before sending it to the factory; but that the old State of Ethan Allan, Brigham Young, W. Pitt Kellogg and Stephen A. Douglass should put glucose into its sugar is too much for us. If Vermont maple sugar is to be diluted at home, the world is about done for. Vermonters, shame on you.—*Farmers' Review*.

Sample Copies of the AMERICAN BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

The National Convention.

The National Bee-Keepers' Association, will hold its Annual Convention in the City Hall and Council Chamber in the city of Toronto, on Tuesday, Wednesday and Thursday, the 18th, 19th and 20th days of September, during the second week of Canada's Great Fair. All the railroads in Canada will issue tickets during this week, good to return, up to Saturday night 22d, at single fare for the round trip. Special excursion rates will be arranged from various parts of the United States, of which due notice will be given. Those who intend being present may be kept posted on the latest excursion rates, etc., by addressing me, and also that I may arrange hotel accommodation. Private lodgings will, if possible, be secured for those who desire it, and every effort will be made to make everybody comfortable. A grand meeting is anticipated.

D. A. JONES, President.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, {
Monday, 10 a. m., July 16, 1883. }

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY.—Extract, honey has commenced to come in freely, and a large crop is reported from all quarters. The demand is very good, and keeps pace with the arrivals. For choice extracted honey I pay 7¢10¢; the latter price for choice clover. I have received several nice lots of comb honey, for which we paid 15¢16¢ on arrival.
BEESWAX.—Arrivals of beeswax are plentiful. We pay 32¢ for a good article on arrival.
CHAS. F. MUTH.

NEW YORK.

HONEY.—Best clover in 1-lb. sections (no glass) 20¢21¢; in 2-lb. sections (glassed) 18¢20¢. Fair quality, 1 and 2-lb. sections, 16¢17¢. Extracted, white, in small barrels, 10¢11¢; buckwheat, 8¢9¢.
BEESWAX.—Is more plentiful. Prime yellow sells at 36¢4¢.

H. K. & F. B. THURBER & CO.

CHICAGO.

HONEY.—The demand for extracted is good, and the market bare of all unfermented honey. Prices range from 8¢ to 10¢. Comb remains lifeless and will until the new crop comes, or until August. Sales of comb are being made at 8¢ to 15¢.
BEESWAX.—30¢35¢.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY.—New extracted is arriving freely—sell for 7 and 8 ¢. New comb coming forward slowly; extra white, 16¢.
BEESWAX.—No beeswax in the market.
STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY.—Some new comb jobbing at 14¢, but old do. nominal. Only a few barrels of extracted and strained sold within quotations—6¢47¢.
BEESWAX.—Sold irregularly from 32¢34¢—mainly at 32¢33¢.

W. T. ANDERSON & Co., 104 N. 3d Street.

CLEVELAND.

HONEY.—There is a moderate sale for best white 1-lb. sections at 18¢, occasionally 19¢, but 2 lbs. are not called for. Extracted has no sale at all.
BEESWAX.—Not offering.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY.—Our market is fairly active. We quote: 1/2 lb. sections at 30¢; 1 lb. sections, 22¢25¢; 2 lb. sections, 20¢22¢. Extracted, 10¢ per lb. Good lots of extracted are wanted in kegs or barrels.
BEESWAX.—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatham Street.

For the American Bee Journal.

A Word of Explanation.

G. M. DOOLITTLE.

By No. 26, of BEE JOURNAL, which is just at hand, I see that the editor thinks I got things a little mixed when I wrote on the "Langstroth frame." I plead guilty to being a poor penman, and, perhaps, was rather unhappy in my expressions, which, together with some errors of the typo, does make the article found on page 318, read somewhat curiously. However, I think the careful reader will see by the last paragraph, taken in connection with the explanation regarding frames in the forepart of the article, what was meant. Perhaps I should have said a frame $11\frac{1}{4} \times 11\frac{1}{2}$ every time when I used the words "Gallup frame," and a frame $17\frac{3}{8} \times 9\frac{1}{8}$ when I spoke of what A. I. Root calls the "standard Langstroth frame," but I feared using so many figures would tend to confuse, and so fell into a worse blunder, perhaps, by using the vernacular of nearly all who write on the subject. In short, I wished to say just this: That nearly all the frames in use in America today were Langstroth frames, and that I wished to express my gratitude to L. L. Langstroth for giving us a practical frame; that from the present outlook I did not believe it possible to make any one frame a standard, no matter how desirable, and that nearly all the frames now before the public were practically good enough; that it was particularly noticeable that those desiring a standard frame were using a frame $17\frac{3}{8} \times 9\frac{1}{8}$, while those using frames of other dimensions were satisfied to let others use whatever frame they desired. Again, that because Doolittle, using a frame $11\frac{1}{4} \times 11\frac{1}{2}$, had been surpassed as to yields of honey by "lots" using the $17\frac{3}{8} \times 9\frac{1}{8}$ frame, while L. C. Root, using a frame $19\frac{1}{8} \times 11$, had surpassed the "lots," did not help Mr. Porter any in concluding that a frame $17\frac{3}{8} \times 9\frac{1}{8}$ was the best of any, and that it should be adopted by all; that because Doolittle, using a frame $11\frac{1}{4} \times 11\frac{1}{2}$, winters bees poorly, while a certain man, using a frame $19\frac{1}{8} \times 11$, winters his bees every time, does not help Mr. Pond's assertion that a frame $17\frac{3}{8} \times 9\frac{1}{8}$ is the best for wintering. Lastly, that the pushing of a frame $17\frac{3}{8} \times 9\frac{1}{8}$ by A. I. Root, in *Gleanings*, and the preference shown by the editor of the BEE JOURNAL for said size of frame, was what had caused it to be used more largely than all others (if such was the case), rather than that it was more meritorious than other forms of the Langstroth frames; that had Prof. Cook edited *Gleanings*, and L. C. Root the BEE JOURNAL, and been as strenuous for their respective size of frames as had A. I. Root for what he terms the Langs-

troth ($17\frac{3}{8} \times 9\frac{1}{8}$), we should have seen a different state of affairs.

In conclusion, that I was "willing that every one (not "any one," as the typo has it) should use a frame $17\frac{3}{8} \times 9\frac{1}{8}$ if they so desire, but I would like the advocates of such a frame to let the people know the whole truth regarding what caused the state of affairs which now exist.

Borodino, N. Y.

[Of course, we well knew what Mr. D. meant, but in a friendly way called attention to his unfortunate manner of expressing it. Now it is quite explicit.—ED.]

Southwestern Iowa Convention.

The Southwestern Iowa Bee-Keepers' Association, met at McPherrin Bros. law office, Clarinda, Iowa, June 21, 1883. A number of members were present. Prof. J. L. Strong was in the chair.

Mr. E. Kretschmer gave a short address, and exhibited the following implements: Simplicity hive honey knife and smoker.

Mr. Strong exhibited comb foundation and Bingham smoker.

Many questions were then propounded and answered, after which an election for officers was held, which resulted as follows: President, J. L. Strong; Secretary, R. C. Aiken; and 8 new members were enrolled.

It was voted to hold the next meeting at Red Oak, Iowa, on May 29, on the fair grounds—that being the second day of the fair.

Each member was requested to take such apiarian implements as he may have, and place them on exhibition at the fair.

R. C. AIKEN, Sec.

J. L. STRONG, Pres.

American Apiculturist.

Honey Bees and Horticulture.

PROF. A. J. COOK.

"If some of our fruit-growers were to write upon this subject, they would place as the title—Bees *versus* Horticulture. Some of our ablest entomologists are persuaded that bees do not always play the role of friends to the pomologist.

What I am to say of bees would apply equally well, in some cases, to many other sweet-loving insects, as the wild bees, the wasps, and many of the dipterous, or two-winged flies; only as early in the season other insects are rare, while the honey bees, though less numerous than they are later in the season, are comparatively abundant, even early in the spring months.

My first proposition is, that plants only secrete nectar that they may attract insects. And why this need of insect visits? It is that they may serve as "marriage priests" in the work of fertilizing the plants. As is well known, many plants, like the willows and the chestnuts, are dioecious. The male element, the pollen,

and the female element, the ovules, are on different plants, and so the plants are absolutely dependent upon insects for fertilization. The pollen attracts the insects to the staminate flowers, while the nectar entices them to visit the pistillate bloom. Some varieties of the strawberries are so nearly dioecious that this luscious fruit, of which good old Isaac Walton wrote, "Doubtless God might have made a better fruit than the strawberry, but doubtless God never did," would in case of some varieties be barren except for the kindly ministrations of insects. Other plants are monoecious—that is, stamens and pistils are on the same flower, but the structural peculiarities are such that unless insects were wooed by the coveted nectar, fertilization would be impossible. Many of the plants with irregular flowers, like the Orchids, as Darwin has so admirably shown, are thus entirely dependent upon insects to effect fructification. In many of these plants the structural modifications, which insure fertilization consequent upon the visits of insects, are wonderfully interesting. These have been dwelt upon at length by Darwin, Gray, Beal and others, and I will forbear to discuss them further.

But many of our flowers, which are so arranged that the pollen falls easily upon the stigma, like the clovers, squashes, and fruit blossoms, fail of full fruitage unless, forsooth, some insect bear the pollen of one flower to the pistil of another. As has been repeatedly demonstrated, if our fruit bloom or that of any of our cucurbitaceous plants be screened from insects the yield of seed and fruit will be but very partial. Prof. Beal and our students have tried some very interesting experiments of this kind with the red clover. All of the plants under observation were covered with gauze that the conditions might be uniform. Bumble bees were placed under the screens of half of these plants. The insects commenced at once to visit and sip nectar from the clover blossoms. In the fall the seeds of all the plants were counted, and those from the plants visited by the bumble bees were to those gathered from the plants which were shielded from all insect visits, as 236:5. Thus we see why the first crop of red clover is barren of seed, while the second crop, which comes of bloom visited freely by bumble bees, whose long tongues can reach down to the nectar at the bottom of the long flower tubes, is prolific of seed. This fact led to the importation of bumble bees from England to New Zealand and Australia two years since. There were no bumble bees in Australia and adjacent islands, and the red clover was found impotent to produce seed. When we have introduced *Apis dorsata* into our American apiaries, or when we have developed *Apis Americana*, with a tongue like that of *Bombus*, seven-sixteenths of an inch long, then we shall be able to raise seed from the first crop of red clover, as the honey bees, unlike the bumble bees, will be numerous enough early in the season to perform

the necessary fertilization. Alsike clover, a hybrid between the white and the red, has shorter flower tubes, which makes it a favorite with our honey bees, and so it gives a full crop of seed from the early blossoms.

In all these cases we have proof that Nature objects to close inter-breeding; and thus, through her laws, the nectar-secreting organs have been evolved, that insects might do the work of cross-fertilization. As in the case of animals, the bi-sexual or dioecious plants have been evolved from the hermaphroditic as a higher type; each sex being independent, more vital force can be expended on the sexual elements, and so the individual is the gainer.

It is sometimes contended by farmers that the visits of bees are detrimental to their crops. I have heard farmers say that they had known bees to destroy entirely their crop of buckwheat by injuring the blossoms. There is no basis of fact for this statement or opinion. Usually bees visit buckwheat bloom freely. If for any reason the seed fail, as from climatic condition and influence, it occasionally will, the bees are charged with the damage, though their whole work, as shown above, has been beneficial, and that only.

It is true, as I have personally observed, that species of our carpenter bees (*Xylocopa*) do pierce the flower tubes of the wild bergamont, and some of our cultivated flowers, with similar long corolla tubes, that they may gain access to the otherwise inaccessible nectar; the tubes once pierced and our honey bees avail themselves of the opportunity to secure some of the nectar. I have watched long and carefully, but never saw the honey bee making the incisions. As I have never heard of any one else who has seen them, I feel free to say that it is entirely unlikely that they are ever thus engaged.

My last proposition is, that though bees, in the dearth of nectar secretion, will sip the juices from crushed grapes and other similar fruits, they rarely ever, I think never, do so unless Nature, some other insect, or some higher animal, has first broken the skin. I have given to bees crushed grapes from which they would eagerly sip the juices, while other sound grapes on the same stem—even those like the Delaware, with tenderest skin, which were made to replace the bruised ones—were left entirely undisturbed. I have even shut bees up in an empty hive with grapes, which latter were safe, even though surrounded by so many hungry mouths. I have tried even a more crucial test, and have stopped the entrance of the hive with grapes, and yet the grapes were uninjured.

In most cases where bees disturb grapes, some bird or wasp has opened the door to such mischief by previously piercing the skin. Occasionally there is a year when an entire vineyard seems to be sucked dry by bees in a few hours. In such cases the fruit is always very ripe, the weather very hot, and the atmosphere very damp; when it is altogether

probable that the juice oozes from fine natural pores, and so lures the bees on to this Bacchanalian feast. I have never had an opportunity to prove this to be true, but from numerous reports I think it the solution of those dreaded onslaughts which have so often brought down severe denunciations upon the bees, and as bitter curses upon their owners.

Essentials of the Coming Hive.

W. H. STEWART.

What to us appears to-day to be true, may to-morrow prove to be untrue. The assemblage of what we now consider to be general principles, deduced from experiment and observation on the subject of bee-culture, may, by some, be considered entitled to the name of pure science. No science is pure, however, unless based upon self-evident truths, as is the science of mathematics. I sometimes question whether the art of bee-culture has become sufficiently understood to be properly called a science.

If we say that two and two equal four, or that four pecks equal one bushel, we speak self-evident truths, backed up by pure mathematical science; but if we ask how many cubic inches are contained in a Wisconsin or New York bee hive, we find that no scientific or positive answer can be given. The reason that no answer can be given is, that no one has as yet been able to demonstrate practically that any one hive in use embodies all the advantages that are found in all the hives of various forms and sizes that are now or have been in use. Even if a hive could be shown to embody all the good points that are found in the many others, there is no certainty that it would not be found wanting in some respects.

The truth is, that not a State in the Union has a hive that gives universal and full satisfaction to all bee-keepers in that State. A hive adequate to every demand of both bees and bee-keepers, every day of the year, and every year, would possess in itself self-evidence that it was constructed on pure scientific principles. When we get that kind of a hive, then every bee-keeper will be as well satisfied of its perfection as they now are that 2 and 2 equal 4, from the fact that that very application of the principle will demonstrate its truthfulness.

The Langstroth hive being shallow, the supers are nearer to the centre of the cluster of bees, and thus many conclude that the bees can be induced to work in the supers earlier in the season than in taller hives. Let us admit that this be true, and that we have thus gained one important point. We find on the other hand that the queen is much more apt to extend the breeding into the super than where tall brood-chambers are used. Also, that very little honey can be stored above the cluster for wintering, and this latter objection alone renders it

altogether unfit for out-door wintering.

If bees are in a tall and reasonably narrow hive, then nearly, or all their winter stores are found in the upper part of the hive, and during a long cold spell, the bees can easily, and do naturally move slowly upward to the top of the cluster to meet the warmer air, and are ever coming in connection with the lower portion of their stores, and can obtain plenty of food without being compelled to make any unnatural or hazardous movement. In low broad hives the stores must unavoidably be at the sides of the cluster, and when we have such a winter as the past, when for 50 to 100 days that bees could not leave the cluster, either downward or in a laterally direction without being chilled to death, they consume what is immediately above them, and then perish with hunger with plenty of food within a few inches of them on all sides.

It is my opinion that the main reason why bees wintered better in the old straw hive is, that on account of its peculiar pyramidal form, the most and best of the stores were in the upper part of the hive, and also, the hive being contracted on all sides alike, the warmer air was confined to the same point, and the bees could easily move about in the midst of plenty.

If a chaff hive could be invented that would embody this point, and the advantages for supers and movable combs in the brood-chamber, as found in the Langstroth, then we might, with propriety, talk about wintering on the summer stands; but broad, shallow brood-chambers with movable combs, either in chaff or straw, will ever fail as an out-door winter bive. Tall, narrow hives like the American, give bees a chance to store honey above the cluster to a greater extent than other frame hives in use; but the open spaces between the combs at the ends allows the warm air to escape laterally, and become dissipated throughout the hive, thus reducing the temperature in and immediately about the cluster. They are also unsafe for wintering on summer stands.

Again, many bee-keepers are of the opinion that the hive should be contracted in early spring, and are experimenting with various division-boards for that purpose. And then again, all the frame hives of which I have any knowledge are, in the months of June and July, found too small to give a prolific queen ample room for brooding. During the two last seasons, I have found hybrid queens using 18 and 20 combs, and each comb 12x12 inches.

Many are now talking of using perforated separators over the brood-chamber to confine the queen to the lower combs for the purpose of keeping the surplus free from brood. This proposition proves that the hives thus provided is considered to be incapable of satisfying the queen in the lower department in the height of the brooding season. And yet again, if it should finally be found most com-

Prairie Farmer.

Extracting Honey from the Combs.

MRS. L. HARRISON.

Many more pounds of honey can be secured by the free use of an extractor than if comb honey is the object. Especially is this true when there is only now and then a good day. An extractor is a desideratum in every apiary, although we prefer to produce comb honey. Many colonies that would not produce a pound of comb honey would yield considerable extracted.

There has been considerable discussion among bee-keepers as to the proper time when honey should be "swung." Some claim that it should be sealed, and well ripened, while others aver that it saves time and honey to extract before sealing, and that the honey is just as good, provided it is kept in a hot, dry atmosphere until it has evaporated to the proper consistency. A prominent apiarist of this State, who runs his bees for extracted honey only, tiers up his hives until the season closes before extracting.

This extracting business is not always smooth sailing. A lady once told the writer that a neighboring bee-keeper brought his machine to their house and extracted their honey. When he was through, everything in the house was sticky; the kitchen floor was covered with wax and propolis, and the bees cross as hornets; when the honey was brought in, they "came also." The key-holes in the doors had to be stopped, and when the bees found they could not enter, they hung in a big cluster from the door-knobs. She emphatically declared that she had enough of it to last her her lifetime. "Why, if I picked up the dish rag there were bees on it, and I got stung, or if I touched the handle of the dipper or the broom, it was the same thing. Whew! But the funniest part of it was when my old man drew on his books in the morning the day after extracting. He is always complaining of the rheumatism, and being so stiff that he can hardly move; but when his foot went down into that boot, he jumped clear over a chair with a yell like an 'Injun.' You see the bees had clustered inside, near the top, and, as he pulled it on, he brushed them down into it, and, as they got pinched, they stung lively."

The extracting should be done in a building by itself, or in a tent inaccessible to the bees. The building should have a revolving window, so that the bees inside could be turned outside. The tools necessary are uncapping knives, an extractor, and an uncapping can. This can has a wire strainer part way down, and is a great convenience, for the honey drains through into the can below, which is drawn off through a gate. Some bee-keepers have a box with folding covers, which has two handles or shafts, before and behind, so that it can be borne by two persons in carrying in the honey to be extracted. This box is filled with empty comb and carried to a hive, when the bees are driven from the

venient and profitable to winter indoors, it is in such case most convenient to set the hives on top of each other, thus building up a wall of hives around the room, and at the same time it is often desirable to have the hive so constructed that we could handle any one, in providing for them without disturbing others immediately connected with the one being handled.

What shall we do? Shall we have a hive that embodies all desirable points, or will we plod along losing in winter what we can save in summer? Do not say that it cannot be done, but let each one strive to develop at least one good point. It seems that if other creatures can have a home that is adequate to all their wants, why not the honey bee?

A perfect hive must embody many good points, and we cannot expect to accomplish all in one day, or year perhaps, but we may proximate, and in doing so let us ever bear in mind that the following points must not be over-looked:

1. The brood-chamber must be easily adjusted to the size of the colony and wants of the queen at all seasons of the year.
2. It must be so that winter stores will be mostly in the upper portion of the hive, and above the cluster.
3. There must be ample top surface in summer for supers.
4. It should be adapted to out-door wintering if possible.
5. It should be constructed so that the bees can be handled at any time of the year.
6. Let the hive be not too complicated or expensive, but cheap, simple and compact.

Let each give their best thoughts through the AMERICAN BEE JOURNAL, and let the only strife be for the perfection of the coming hive, and ultimate success of bee-culture.

Orion, Wis.

For the American Bee Journal.

The Standard Frame.

W. H. HARMER.

I am much obliged to Mr. Hutchinson for his article on page 308; I am glad to hear of anybody adopting the Langstroth hive, and also to Mr. Heddon for his, on the next page. The want of a standard frame I am sure is felt by every busy honey-producer. I used to think the same as Mr. Hutchinson in regard to the necessity of the frame holding eight 4x4 $\frac{1}{2}$ sections, but I have got over that. I believe the Langstroth frame to be long enough, and that broad frames for sections will soon be a thing of the past. I think Mr. Hutchinson would say so too, if he ever used the Heddon section rack. It seems to me there is unnecessary wood and work about the broad frame system, and it is not nearly so easy to manipulate, as the rack above mentioned. We must come down to a point where there is only the necessary handling, if we want to turn those silver-lined clouds to a golden hue.

I have used a deeper and shorter frame before I took to the Langstroth; and to take a deeper one now would make me feel as if I was going backwards. I will here quote two lines out of "Langstroth on the Honey-bee," page 330: "The deeper the frame the more difficult it is to make them hang true on the rabbets, and the greater the difficulty of handling them without crushing the bees or breaking the combs."

Let every beginner make a note of this, for it is one of the points on which successful bee-culture rest, and one that troubled me ever since I saw the first movable frame, until the joyous news came of the wiring process; whoever the inventor is, he will always have my heart-felt thanks.

It stands to reason that we ought not to play leap-frog with our frames of bees and brood, if we have not got perfectly straight combs. I can tolerate no others in my apiary, and to get them so, they must be wired. But to return to the subject, I think there is room in the Langstroth hive for a frame two-eighths of an inch longer if any one wished to produce comb honey in that way. I should like to say a good deal more on the subject, but I am a very slow writer, besides I do not wish to take up too much valuable space. I think Mr. Hurst will find a very good answer, in the above, to his question in the last number of the BEE JOURNAL.

Manistee, Mich., July 6, 1883.

For the American Bee Journal.

Do Queens Not Mate More than Once?

S. HINMAN.

Is it regarded as an established fact that queen bees mate with the drones only once? Prof. A. J. Cook says, on page 310 of the BEE JOURNAL, that Mr. Alley is surely right in saying that queens mate only once. My experience with queens leads me to think that there are exceptions to the rule.

In 1880, I commenced to Italianize my apiary by purchasing an Italian queen from D. A. Jones. I introduced her successfully to a queenless colony of black bees on July 7; on Aug. 27, I succeeded in introducing a young queen, reared from the brood of the Jones queen in another colony of black bees. This hive I looked into very often, in order to see how the daughter of the Jones queen was coming on. In due time, the eggs, larvae and sealed brood made their appearance in the hive. On Sept. 24, as I looked into the hive, I saw most unmistakable signs on the queen of having mated with a drone that very day. At the same time there were eggs and brood in all stages, and sealed brood on the same frame with the queen. I think there can be no doubt about its being the same queen that I introduced on Aug. 27, as there was no unfertilized Italian queen in my yard, that could have usurped her place in the hive, and outside of my yard there was not an Italian colony within five miles of my place.

Dundonald, Ont.

combs with smoke from a bellows smoker, and the remainder brushed off with a feather, or asparagus tops, as they are taken out, and their places filled with empty comb. Others have a similar box for carrying combs, fitted on to a wheelbarrow, and those who extract on a small scale have a tin bucket with a cover, suitable for carrying 5 Langstroth frames.

A very sharp knife is necessary to remove the cappings so that the comb may be marred as little as possible. Honey can be extracted from combs containing brood, but it is seldom done. If the brood is uncapped, the machine has to be turned gently, or it will be thrown out. We do not want "grub juice" in our honey, so we let these combs alone. It is not necessary to strain the honey unless the operator desires it, though we always do, as all bits of comb rise to the top.

When white clover honey is extracted neatly and kept by itself, it is one of the purest sweets known. It is one of the best known remedies for coughs and colds—a boon for consumption and persons of weak digestion. When Mrs. L. L. Langstroth was thought to be dying with consumption, she commenced taking pure honey, a teaspoonful at a time, as often as possible. She recovered and lived 10 years, dying of some other disease. "Eat thou honey, because it is good."

Peoria, Ill.

For the American Bee Journal.

Bee-Moth, its Depredations.

THOMAS BALCOMB.

There seems to be a considerable amount unsettled in regard to the theory of the bee-moth. I have noticed more than once many conflicting theories; notwithstanding the "so-called" pest, is but a small enemy to the advanced apiarist, yet it is as well that something more definite should be arrived at. I find that a vast number entertain the idea that the moth must enter the hive and deposit its eggs over the combs to propagate its species. Others think the moth lays its eggs on and around the alighting board; and many, with myself, think that the bees unconsciously carry the eggs into the hive, while gathering the pollen from the various plants.

I find much difference of opinion as to what the moth or worm wholly subsists on. Dr. Howard, in the Texas Bee-Keepers' Convention, said that the so-called bee-moth subsisted "wholly" upon honey comb, as constructed by the bees; that comb foundation made from pure wax was not attacked; that comb constructed from such, was only infested for the sake of the additional comb; he said that Judge Andrews called his attention to this a year ago, in a remark that the moth larvæ cannot subsist upon pure beeswax.

Now, I certainly beg to differ from these gentlemen's views upon the subject; for I am fully convinced that the moth and its worm do subsist on substances other than beeswax.

I have noticed that the moth seems more plentiful in the fall of the year, particularly if it has been wet and sultry weather. It does not seem feasible that this super-abundance of the moth could have had their beginning inside of a bee hive, and wholly upon "honey comb." I think (and Dr. Howard's statements partly bear me out) that the moth eggs are not only deposited in the cells with the pollen, but the eggs are "worked up" by the bees in manipulating the wax for cell building. That is the reason why the natural comb is more infested by them.

I presume Judge Andrews had reference to pure beeswax that had been "melted down," when stating that the moth larvæ could not subsist on pure beeswax. But I have more than once found that, to a limited extent, the moth grub will even subsist on pure melted wax. I think the small square I have sent you, Mr. Editor, for examination, is as pure as wax can be, yet you see it is partly eaten up. I have had dark (melted) wax badly eaten when kept with pieces of old comb, and neglected.

Mr. M. D. Davis, at the same convention, asked if these worms could subsist upon bee bread. My experience has been that the worms mostly originate in the pollen. I find after consuming the pollen, they then attack the wax. The piece of comb that I have sent for examination was drawn out, last year, from moulded foundation; a few bees were reared on one side, as you perceive. This year I put the comb into a hive and the bees commenced putting in pollen where the brood had been; but, having to double up some, I took out the comb and put it with some others, in an empty hive, to experiment with, and the result is that in a few days the worms have hatched out in that freshly-deposited pollen, and they are subsisting "wholly" upon that, but will commence on the comb whenever the pollen is consumed.

Whether the worms, when in hives, attack the bee larvæ, I cannot positively say, but I believe that they will even subsist and thrive on a diet partly of bee larvæ. For, last year, I unfortunately had to make some experiments that were rather costly. I had let fall into a shapeless mass two frames of solid brood (excepting a little honey and pollen); they had just been drawn out on moulded foundation. I, therefore, put them into a clean coal-oil can, securely tying cloths over the top, so that no small insects, much less a bee moth, could enter, but in a few days I could detect the worm, and watched their gradual progress, but in less than two months it was one mass of moth worms and webs.

Now, in the first place, the combs were quite new and had their first "batch" of brood; they came from the centre of a strong colony of Italians, where I know that neither moth worm or anything else would be tolerated, but all was entirely eaten up, and I know, without a doubt, that no moth ever touched those combs. Therefore, I have long ago been

forced to believe that comb and bees are seldom destroyed by the moth itself entering the hive; but that the eggs are deposited in the honey and pollen-producing plants and flowers, and are carried in by the bees themselves.

Furthermore, I fully believe that the moth will thrive and multiply on substances and in places other than the wax, and the home of the honey-bee. I hope for the benefit of those that are in such dread of the moth worm, that my brother bee-keepers will not let this subject drop, for I think it quite essential that we should have a thorough knowledge of the enemies of the honey-bee, as well as of the industrious little fellows themselves.

Luling, Texas.

[The cake of wax and piece of comb mentioned by Mr. Balcomb bear unmistakable evidence of being pure wax, and yet it is infested with the moth and partly eaten up.—ED.]

Read before the Texas Convention.

Different Races of Honey Bees.

W. K. MARSHALL.

The modern improvements in the management of the honey-bee has led to the inquiry whether the bee itself cannot be improved. Hence, we have been looking after an improved or superior race of bees.

Every species of the honey-bee may probably be embraced in two general classes: the yellow and the black bee. The different varieties are probably crosses of these two races. It is generally supposed that there are two varieties of the black bee; a vicious little fellow, but a good worker, and a large light-colored bee. I have never been able to see the reason for this distinction, and have thought that the difference was owing to the management and other circumstances. I have found that the larger lighter-colored bee produced the most honey, even before aided with the modern improvements. I think the black bees are all of the same race, and not much difference in their temper or honey-producing qualities.

The yellow bee appears to be a distinct species, both from its marking and temperament. It probably originated in Egypt, and spread from there to the Holy Land. The Egyptian, and bees from all the surrounding regions, are so nearly the same in markings and temperament as to point to them as the same race; climate and method of management have made the difference in their habits and appearance. The Italian bee I consider an importation from the bee of Palestine. Their markings are nearly alike; their habits and temperament are the result of climate and management. Of all the different races of bees, already subjected to our improved modes of management, I consider the Italian the most desirable. I have found the Holy Land and Cyprian bees prolific and good

workers, but cross, easily disturbed, nervous and hard to manage. For practical purposes, at least for the present, I would not advise an extensive cultivation of them. The light-colored Italians, with three yellow bands, clearly marked, are certainly the purer stock. The dark-colored Italians with the yellow bands narrower and not so clearly marked, undoubtedly have been tintured with the black blood. This probably comes from contact with the German bee. The question whether this taint of black blood has not produced a superior bee for practical purposes is still an open question. My experience with the dark-colored Italian bees, gave me a very high opinion of their merits. I had a dark-colored imported queen, whose progeny were the most docile and the best workers I ever had. They were certainly not pure, for while they generally were all marked with the three bands, occasionally there was among them a sport, pointing look to the black blood. Undoubtedly the light-colored clearly-marked three-banded Italians are the pure stock, and the ones we should breed from. If a tincture of black blood is desirable, it can easily be obtained.

As to the question which is the best bee for practical purposes, I answer, so far as has yet been demonstrated, the Italian. They may probably be improved, and "the coming bee" may not yet be developed. Undoubtedly the bee, to some extent at least, is subject to the same laws which govern the whole animal world. By selecting the higher grades, and breeding up, we may reach a degree of perfection not yet obtained.

I would recommend the light-colored bee to breed from, until "the coming bee" has arrived, and when a greater degree of perfection has been reached, we can then take the higher grade and keep it up to the degree of perfection already obtained.

As the question is, Which will pay best, this or that, and all things considered? I can make the Italian pay best. I select it in preference to any already in the field. Nor have I yet seen any improvements which very materially beats the original Italian. I think I have seen home-bred queens which fully equaled any of the imported, but I have never seen any mingling of blood, thence I am very much disposed to stick to the pure Italian, unadulterated.

Marshall, Texas.

Securing Straight Combs.

C. HARROLD.

In answer to the inquiry of J. Hurst, on page 338 of the BEE JOURNAL, I would say: Take a long-bladed knife and pass it down between two of the outside combs, as best you can, removing one comb; this gives you room. Now if the next frame has a comb partially extending across 3 or 4 others, gently pass the knife between the comb and bottom bars, then along

up the end, to the top bars, then back to the second frame again, holding the comb up with the hand; now press the comb straight, and if it is too long for the frame, pass the knife through the comb, leaving it long enough for the frame; press it in the frame, and fasten it to the top bar by pressing it with the thumb. If the comb contains honey, cut out the ill-shaped end and extract it; then place it in the frame as before described. The knife should be wet in clean soap-suds directly before using each time, and so continue until the combs are all straight.

First plumb your hive (it does no harm to pitch them a little to the front, so that the bees may drag out the cappings while at work). If foundation is not used, you can take small bits of comb, and wax them to the top bar with the thumb, 3 or 4 bits on every frame. Whenever the bees commence building their combs crooked, straighten them and change the frames, so that the bees are compelled to build it straight. You can probably turn the frame, end for end, with less work, and it may answer all purposes. I think, if you turn your frames every 3 or 4 days, you will have no trouble.

Onawa, Iowa.

Translated from *Bienenfreund* by A. R. Kohnke.

Dzierzon's Theory of Wintering Bees.

N. N.

At last Dr. Dzierzon has written an extensive article in defence of his theory that "bees during their winter rest could not be housed too warm, and if it were possible, they would be much better off in a temperature ranging from 75 to 95 degrees F., than anything below that."

All bee-keepers are agreed that success in wintering is the foundation of success in bee-keeping, and a further discussion of this question would advance the interest in bee-keeping largely, by showing that well and warmly-protected bees should winter better, and also to show the fallacy of those bee-keepers who, contrary to this theory, have found it more advantageous to their bees and themselves to give them less protective and more ventilation.

It may be quite interesting to hear of the experience of a bee-keeper from the North (58 lat.) who casts his vote in favor of "cold" wintering (little protection), and *why* the reasons Dr. Dzierzon advances to support his theory, have not been acceptable to him. A "cold" wintering would certainly show its disadvantages, if it were such, in a cold climate, much colder than Germany. The writer of this article has now for 4 years wintered his bees with little protection from cold (which last winter lasted 6½ months), and never lost a single colony. No dysentery, no moldy combs, few dead bees, and the excrements and other dirt on the bottom board as dry as powder. Most, or at least very many of the bee-keepers in Germany follow the teaching of their master, and, according to his theory,

have their bees well housed and protected. In spite of this I noticed:

1. Poor wintering in Germany and other countries during hard winters.

2. Continual complaints about poor wintering, in bee papers.

3. The complaint that colonies in frame hives winter much poorer than those in box hives, gums, or straw hives, contrary to Krasiecki's assertion of the opposite being the fact.

4. That even Dr. Dzierzon and Berlepsch corroborated them as being disadvantages of the frame hive.

5. That the writer of this article has had the very best of success by adopting the opposite course.

6. That the bees in the Northern and Eastern part of Russia, being confined 8 months to their hives winter very successfully.

7. Hilbert's opinion, that "though we owe Berlepsch very much, his wintering theory has caused bee-keepers great losses," especially by two of his doctrines, that 1st, bees need very little air during wintering, and 2nd, should "be most carefully guarded against ventilation."

And finally, Stlh, on seeing bees wintered in his neighborhood by a lady bee-keeper, after the old style, in gums standing in the garden in a very exposed position and expressing his surprise about it, she smilingly replied: "These animals are not afraid of any cold." The walls of these gums are no thicker than 1½ inches. She only once lost one colony on account of cold, because the walls of the gum were very thin. It has also been observed that bees packed or housed always winter poorly, and the knowing ones never protect them in this country.

Dr. Dzierzon uses repeatedly the expression: "A bee is no ice bear (white bear)." Certainly not; for within the Arctic zone we find no bees; a single bee is a helpless, delicate creature. But a colony of bees is like a bear, and where a bear winters, there a colony of bees will. This is proven many times over, but it requires a strong colony, and only strong colonies should be considered in discussing theory of wintering. Weak colonies are diseased colonies, and must necessarily be treated as a patient, wrapped up well in cotton, and belong more appropriately to apistical pathology than in the wintering question.

It seems to me that Dr. Dzierzon reasons in a question, requiring practical experience, from assumed but not proven facts. This reasoning from such has led him into error, as is proven by the experience of many other bee-keepers, whose observation corroborate the contrary of his assertions. The writer has wintered his bees successfully without any protection, with two openings in the hive; one at the bottom and another half way up the hive, and that in a temperature of from 30 to 40° below zero, and the bees having wholly been confined to their hives in different years for 6, 7 and 8 months. It would be an easy matter for any bee-keeper to try to winter a colony in a temperature of say 70° or 80° by putting an

observation hive in a window in his room, where the temperature does not fall below the heat required by Dr. Dzierzon. It would be interesting to know his verdict in this question; by such decisive experiments the science of bee-keeping would gain largely.

Remark by the Translator.—I obtained, this spring, a colony of bees from a frame in an old rotten box-hive; as it had no legs, which were, perhaps, rotten some years ago, it was propped up and nailed to two posts, about one foot from the ground; the bottom board was entirely gone, exposing the combs to view. On top were two open inch holes not at all covered; it had always wintered well; had stood there for many years, and swarmed occasionally, but never had it given any surplus honey. On transferring it to a Langstroth hive, I found plenty of bees and brood and two capped queen-cells.

For the American Bee Journal.

Wintering Bees.

JAMES HEDDON.

As an excuse for coming forward again with this old, old subject, I will say that it is not yet exhausted.

Loss in wintering is considered by many the arch enemy of the bee-keeper. I am just one year late or behind the time I expected with this article. In the fall of 1881, I prepared a large number of colonies in very many different ways, wishing to somewhat test the effects of different conditions upon the main cause of loss in wintering, namely dysentery. The open winter following, which gave the bees a chance to void every two or three weeks, which we all know to be a prevention or cure or both to the malady, prevented my experiments from teaching one any thing upon the subject.

Last fall I repeated my previous experimental packing for winter, and as you know, was favored by a winter long enough, and strong enough to satisfy the most enthusiastic truth seeker. As I have much else to say, I will not go into a detailed description of my modes of wintering. I will give you my own deductions in as short a space as possible.

These experiments verified my former opinion that cold and confinement is not the main cause of dysentery. I do not remember the time when my bees were confined longer or subjected to longer extended low temperature than last winter. There has not been a time since I kept bees, except one winter when I had 33 colonies, that dysentery has not shown itself among the bees to a greater or less extent. One year I lost 60 colonies out of 73, another 45 out of 48, another year near two-thirds, another about three-fourths, and once or twice one-half. Once (with the 33 colonies above referred to) all came through in perfect order. If cold and confinement were the cause of dysentery (dysentery being the well known cause of our winter losses) of my 350 colo-

nies put into winter quarters last fall according to the above experience, I should not have had 5 colonies left alive. As it was I lost a little over 150 colonies out of 350. Many colonies came through in perfect condition.

My favorite experiment was made with 50 colonies, 45 of which came through in good condition with the exception of 3 or 4 which had fertile workers, being overlooked during my absence in the fall, caused by severe poisoning from breathing the odor of bees at that time of year. My own experiments are not alone in proving that cold and confinement are not the cause of dysentery, but only one of the necessary conditions; as a temperature above the freezing point is a necessary condition for yellow fever, though heat is not the cause of it. On page 218, of the current volume, Mr. D. L. Herrick, of Vermont, says that Mr. McKay wishes to know if any one can beat 130 days without a flight, and says he can. Says his bees had been confined 159 days, and the whole 21 colonies answered the roll call, all seeming in perfect condition on April 15.

Many reports like this can be found to back up my opinion. I have demonstrated to my own satisfaction that upward ventilation, downward ventilation, dry atmosphere, damp atmosphere, and many minor conditions only act for or against the great cause in a mild degree, and then much according to the condition of the bees. I am now perfectly satisfied, though I admit there is still room to be mistaken, that the cause of dysentery lies in the food eaten by the bees, and I firmly believe that what is known as "Heddon's pollen theory," gives the correct solution to the subject.

I will quote the following from a private letter from that able apiarist and careful student of nature, Mr. A. R. Kohnke, of Youngstown, O.: "There are only two substances in the hive for the bees to eat, namely honey and pollen. We know honey is a pure carbon sweet, at least practically so, and if eaten in small quantities by bees, is converted into carbonic acid and water, hence leaves no residue. But pollen contains a much larger per cent. of undigestible matter which has to be voided as feces; it must, therefore, be the pollen. That is what you say. It is pollen first and last. Now hold on; not so fast. During the winter the bees have nothing to do but to sit still and breathe, not breed. To breed, they need and must have pollen; but to breathe they need not. I want to know why they should eat pollen when they do not need it. An answer, a correct answer will bring us to a true and correct starting point. Could you bring about such a condition with bees as would force them to eat honey when they want pollen, or pollen when they want honey? Will bees of their own choice eat the one when they are in need of the other? You may, perhaps, say you do not know, but I rather think you do. Bees are not yet enough civilized to accept substitutes of one for the other, 'and make it do.' They do

not. They will not touch your pollen if they have honey or some other pure hydro carbon sweet within reach. If they have not, they eat not only the honey but the pollen also, of which a large part is covered with honey, and then the accumulation of feces begins. If at this stage the weather permits a flight, they will improve the chance and then move around to honey, and no dysentery will be visible, if not it is there."

It seems that this letter of Mr. Kohnke's is meant by him as a partial controversy with me, while the facts are, it precisely substantiates my favorite opinions and claims. I have said all along that bees unhesitatingly prefer honey if the quality is good, but do not eat pollen except when they are out of normal condition, by the honey being all eaten out of their immediate cluster, and the weather too disastrously cold for the bees to move. Or when breeding begins, I think the bees, in handling the pollen, swallow more or less of it, for some way or other breeding and dysentery keep company to a great extent.

Very many bee-keepers, who are now observing and experimenting somewhat regarding the pollen theory, are writing me that they believe it a correct one. Among them, Mr. Walter Harmer, of Manistee, Mich., writes as follows: "Two colonies came through all right; the only one that had dysentery, had an excess of pollen, and began to breed the earliest. Now, I wish to quote from a gentleman who has experimented, perhaps, more than any other living man upon this question, namely, the consumption of pollen as connected with dysentery. I refer to Dr. A. B. Mason, of Wagon Works, Ohio. In a letter under date of March 20, last, he writes as follows:

"I've just been reading the *Exchange* for February, and I notice Mr. Tennant's remarks on your pollen theory; he does not believe that pollen alone is the cause of dysentery, etc.; I had to laugh. A good many illustrations popped into my head, and the first that occurred was, that I would be laughed at too if I was to say that, when a man is hung for murder, the rope around his neck was not not the cause of his death—his getting his neck into the rope is the cause of death; so of course, pollen is not the cause, it is 'cold weather without purifying flights.' I wonder what do bees want 'purifying flights' for, if they do not eat impure food? I like to read occasionally what Mr. Cheshire says on page 277, of the *BEE JOURNAL* for June, 1879.

"As I wrote you, once before, I have wintered for 4 years without pollen, and without loss, but this winter I am experimenting, not for choice but necessity, and I am going to pay for it, too. Being partially paralyzed in my wrists, for several weeks last fall, I was unable to prepare all my colonies for winter without pollen. I put 77 colonies in the cellar (where I have wintered them 2 years without loss), last Nov. 18, in a pile, 13 hives long and 6 hives high, without any regard to their condition, only putting

the heaviest in stores at the bottom, having previously marked every one with pollen, and its location in the hive. Now for the result, so far. The colonies with pollen nearly all have dysentery, and those having the most pollen in the cluster, have it the worst. Perhaps you will say, how do you know this? Well, last week we had two days, nice and warm, and I took most of the colonies with dysentery out for examination and a flight, and found as above stated. All were clean inside, aside from dead bees; no daubed combs. I shall lose from 'spring dwindling.' You go 10 to 1 on the pollen theory (it is no longer theory with me), but I can beat you on that, for I say 100 to 1, and more too, in practice. You notice that nearly all who give directions for wintering say, 'plenty of good honey, or sugar syrup; why don't they say, 'and pollen,' if it is a good thing to have in winter. Some of my dysenteric colonies have eaten the honey and left the pollen, and show but slight signs of dysentery."

From all of the above, I form the following conclusions:

1. Dysentery is the cause of our winter losses, to which all other losses are "as water unto wine."

2. The consumption of bee bread, or perhaps floating pollen in the honey, during the period in which the bees cannot void the residue necessarily accumulating from it, is the cause of dysentery.

It now only remains to devise some off-hand practical method, not a complicated and cumbersome one, or one which subjects one to stings or robbing, with which to put up bees, in such shape for winter as will avoid the conditions which are productive of dysentery.

These points I am working at, and when it is all accomplished, it will be time to announce our success, and the "what and how" of it, when I have made such success positive and permanent.

Dowagiac, Mich.

Gleanings in Bee-Culture.

Observations on Several Topics.

L. L. LANGSTROTH.

On page 55 of my work, you will see that I noticed in 1852 (as I see from my journal, and not 1854), drones reared under the same circumstances, so frequently referred to by some of your contributors. If the spermatie filaments of the drone remain sometime upon the surface of the egg, it is easy to conceive that the bees can remove them before they get into the micropyle of the egg, and hence drones instead of workers.

I wish to make some suggestions for the improvement of your standard chaff hive. You will remember, that years ago you asked for some practical way by which the frames could be inserted in the top story so that it would not be necessary to remove them all in order to get access to those below. I think that this can be done, not only without injury to the

main features of your hive, but with an increase of storage room above for frames or sections, besides other advantages.

Let me begin by saying that the doubling the case of the upper story is not only unnecessary for the protection of the bees below, but a positive injury to them, in the winter at least, by making that upper story like a damp cellar, and preventing it from drying out as it always does when made of a single thickness. This is one reason why the chaff cushions in your hive are so often damp, when in those I have made, they are comparatively dry. Let your top story be made of single thickness, and you not only get rid of this evil, but have much more storage room, either for frames or sections. Not only so, but you gain just the room which you need for easy instead of cramped access to the lower story. There is good room for your arms, for want of which, even when there are no frames to remove from the upper story, I always dislike to manipulate with your hives, especially if there is much work to be done.

Suppose, now, that you have all the room which would be gained by a single thickness of the walls of that story. I will show you how to arrange that space for frames, by a

simple plan which I used very successfully more than 15 years ago. My upper stories were made of only $\frac{1}{2}$ -inch stuff, and were strengthened by four posts, screwed one into each corner. These posts did not come up level with the sides of the cover, but were kept just enough below to allow frames to rest upon them (a, a), a little below the frames which sit from front to rear in the upper story (b, b). To sustain these frames, thin rails of hard wood, about 3 inches wide, with upper edges beveled to a sharp edge, were fastened up against the corner posts. The dotted lines represent these rails. You will see that the space in front and rear of the upper frames was utilized for holding storing frames, which also prevented the bees from building combs between the upper set of frames and the front and rear walls of the upper case of the top story. In the hives I used, in order not to use frames resting on the corners, of a different size from the standard Langstroth frame, the lower story was made to hold 13 frames, in a brood-chamber $18\frac{1}{2} \times 18\frac{1}{2}$, instead of $18\frac{1}{2} \times 14\frac{1}{2}$; but there will be no need of your chaff hives holding more than 10 below. By using smaller frames than the standard Langstroth, or dummies instead of frames, any standard Langstroth hive might be made on this plan.

If you wish to get access to any frame below you need only remove one or two above, moving some of the others nearer together, and there is nothing to prevent you from lifting out the lower frame, the rails on which the upper ones rest being no hindrance at all.

In this way you avoid all the heavy lifting, and other trouble incidental to the plan of the old two-storied hive, when you desire to get access to the lower story. If you still, for any reason, desire to have the upper walls of your chaff hive double, you can avail yourself of this plan, by making the air space very narrow; but in my opinion the hive is much better if single thickness above.

There was a time when I would have tried to patent this plan; but while I neither question the absolute right of any inventor to patent any original patentable device, nor the absolute wrong of parties who knowingly infringe upon valid patents, as a matter of plain business common sense, I would advise against patenting devices which can so easily be appropriated by others, as almost every thing connected with bee-culture must necessarily be. Where the manufacturing of any patented article requires costly buildings and machinery, and heavy capital, men will think long and often before they attempt to infringe upon it; for in their costly plant they give ample guarantees to those who will defend their rights. On the contrary, if a man could invent the most useful article that human brains ever devised, but which could be easily and cheaply made by almost any one; in order to reap any substantial benefit from his patent, he must expect, as the rule, to engage in almost endless litigation, and to spend one fortune in trying to make another. I hope that you will make at least one chaff hive on the plan I have suggested, and put it to the test of actual use in your apiary.

Last year, in this place, at this time, the weather was most propitious, and the fields and roadsides white with clover; but it had no perceptible fragrance, and the bees in my neighbors' apiaries had to be fed to be kept from starvation! This year, notwithstanding the frequent and drenching rains, our houses are sweet with the smell of clover; and in the intervals when they can work, the bees are accumulating stores at a great rate.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich

Comb Production.

Will Mr. Jas. Heddon please tell us if will pay to feed extracted honey, costing 10 or 11 cents per pound to get comb, to sell at 20 cents? Our honey season is over till fall; if this plan will pay, I can keep my bees at work during honey dearth.

D. W. BELLEMEY.

Vienna, Ill., July 8, 1883.

ANSWER.—A few say that it will. Very many say they have found that it will not, and have paid for the lesson. If you will try it this season, I will venture to say you will be found among those who fail to make it practical. I have not believed it practical, hence, have not tried the experiment.

Transferring.

In answer to Silas R., on Transferring, on page 315, Mr. Heddon says: "We practice transferring either on the old system or the new." Please give us both systems in the next number of the JOURNAL, and oblige several subscribers who wish to know for our own benefit. Give us light on this subject.

D. F. MARKS.

South Bosque, Tex., June 27, 1883.

ANSWER.—I will have an article on Transferring next week, in which I will give and compare both systems.

What is the Cause of It?

Please answer these questions in "What and How" department:

1. When a virgin queen leads a swarm, does she mate with the drone while swarming?

2. What is the cause of bees, where they are on the outside front of hive, having a back-and-forth motion, heads downward, mandibles against the hive, like as if they were rubbing them against the hive?

3. When I open a hive and am lifting out frames, on some frames several bees will begin to shake themselves like as if they were trying to shake loose from their legs—what is the cause? J. A. P. FANCHER—34.

Fancher's Mills, Tenn., July 9, 1883.

ANSWERS.—1. No; such is not the rule, though I do not know that such might not happen under some conditions. As a rule, the age of the queen forbids.

2. I once found out the cause of this see-saw movement, but have forgotten it, and who told me, as it is not radically connected with our success or failure.

3. I have been told that this shaking motion is to remove particles of pollen that still adhere to the legs, but I

have always been too busy with the dollar and cent points of the business, to stop and carefully look into these unimportant matters. They are of most importance to the apicultural entomologist, and I presume Prof. Cook can answer these questions easily and satisfactorily.

SELECTIONS FROM OUR LETTER BOX

Horsemint a Failure.

Our main honey plant, the horse-mint, failed to yield honey this year, on the account of drouth. Last year it beat anything I ever saw; my bees filled their hives in 3 weeks; it bloomed about 8 weeks, yielding all the time. I have to feed some of my bees now, to keep up breeding. For the fall plant, we have the smart weed; I notice thousands of it springing up all around the lakes, and it never fails to yield honey. I will now name some of the Texas honey plants: First, fruit bloom, then willow, you-pou, rattan, persimmon, hoarhound, horsemint, wild ivy, elder, dog fennel, wild sage, smart weed, native cotton, and a hundred other different varieties which yield more or less. Please tell me how to make winter feed, and how much it will take to winter a colony.

W. S. DOUGLASS.

Lexington, Tex., June 28, 1883.

[For feeding in fall for winter stores, 3 pounds of coffee A sugar and one pint of boiling water, simmer five minutes. Feed this inside the hive with a division board feeder, or in a tin can with a coarse cloth tied over it, and inverted on the frames. For fall feeding, estimate the amount required, and give it as fast as the bees can store it in the combs. For winter feeding, use four parts coffee A sugar and one part water; simmer till it becomes quite hard on being cooled, mould into frames of one inch thickness, and lay it on top of the frames, using sticks underneath one-half inch square; or mould it in brood frames, tie hemp twine around to hold it in place, and put it in the center of the brood chamber. Each colony should have 30 pounds of good honey for winter stores, in the North, but in Texas, it needs much less.—ED.]

Lots of Honey.

I have just arrived home from San Antonio, Texas. Bees are doing nothing there at present; the weather is so very dry. Will return there again in the fall. Bees are doing finely here, swarming right along, laying up lots of honey.

A. C. BAILEY.

Brooklyn, Iowa, July 9, 1883.

Bees Doing First Rate.

I am building a new bee house 16x20 and 16 feet high. I am going more extensive in the bee business. Bees are doing first rate. The linden has not commenced to bloom yet, in my locality. I had a small swarm queenless, on the first of June. I gave it two queen-cells; one of the queens hatched, got fertilized and laid eggs in worker comb in three days; all this time the other queen was not allowed to hatch, and the eighth day after the first queen hatched, they swarmed.

REESE POWELL.

Mineral Point, Wis., July 10, 1883.

Sourwood Honey.

This season I have been trying Prof. A. J. Cook's plan for the prevention of increase, by putting swarms into colonies that had swarmed a few days previously, giving supers filled with foundation, after destroying all queen cells, and they invariably swarmed again in from 10 to 13 days, but now they have stopped since July 5. Sourwood began to bloom on June 26, and is now booming; the honey is very thin—clear as crystal, and, when fully ripened and thick (which takes till about Sept. 1), it is, to my taste, the finest honey of any. It has the most delicate flavor, never cloying the appetite like some honey does. After ripening in the hive, it turns to a pale yellow and is very thick. The sourwood will continue in blossom till the last of July. Bees do not gather honey as rapidly from it as they do from poplar, but the sourwood holds its own longer, and we get more surplus from sourwood, when the season is favorable, the bees being always strong when it is in blossom. Our ridges here are covered with it, not exclusively, but mixed among the oaks and other trees.

J. A. P. FANCHER.

Fancher's Mills, Tenn., July 9, 1883.

Mistaken Economy.

With all respect to Mr. Doolittle, I would say that he gave, sometime ago, what looked well on paper, and I thought I had "struck it" when I read it, which was to save foundation by hiving bees on empty frames for a few days, then to add foundation. I have tried it, and found it mistaken economy, if foundation can be had. I have proved that bees often swarm without being able to produce much wax for 48 hours. Some of my bees did good work at once on foundation, by raising the cell walls without being idle or producing wax at the expense of honey. If bees hang out a few days and prepare for swarming, they will give much better results on empty frames. Next, when I saw my stock of foundation costing \$50, I began to wonder if it would pay. I used half sheets, to see if I could not sell some foundation. I guess not, for about 12 in the dozen were filled out with drone comb below the half sheets, especially if put in before swarming. No more half sheets on these premises. To get strong, well puffed out combs, keep the extractor away until all are well drawn. I let my bees swarm naturally, and put

them on full sheets of un-wired foundation (sometimes a pail full of bees), and have yet to see the first sheet to fall when put on as you recommend. This is the wettest summer known in this part, but we have a large crop of clover and thistles, also, I think, about 5,000 basswood blossoms to one last year; they may not be out till July 20. I am surprised at so much being said on wintering bees, and of those having cellars, giving reports as soon as they are carried out. How bees pull through the spring, after being cellared; this is the grand point. I kept my outside boxes on many colonies until June, and still had losses in the spring. But my neighbor has only a handful in one hive, out of 27 kept in a good cellar. They had not even started egg-laying when set out, and could not stand the spring dwindling, while mine will be doubled in a few days, by natural swarming, if we get a honey shower equal to the appearance of basswood. Your pamphlets on "Honey, as Food and Medicine," ought to be scattered lively. I think bee-keepers would consult their own interest to use them.

CHARLES MITCHELL.
Molesworth, Ont., July 9, 1883.

Honey a Failure in Alabama.

Last season was an entire failure, and the present one bids fair to be partly so. Poplar did not yield its usual quantity of honey this year, and it was nearly all used up in rearing brood, and putting the bees in good strength for work. About the 20th of June the linden commenced to open its bloom, but yielded very little honey until the last 10 days. We have not, as yet, taken off an average of 5 lbs. of honey per colony, while other years we would have taken 40 lbs. We may get a yield of late honey.

NELSON PERKINS.
Princeton, Ala., July 10, 1883.

Basswood Honey Next.

Bees are doing fairly this season, though they are slacking up now. Basswood will be in blossom in about a week, and then I am in hopes they will go ahead again. Last year there was no honey to speak of here, and a large proportion of the bees starved to death.

A. C. BALCH.
Kalamazoo, Mich., July 7, 1883.

Finest Honey Ever Seen.

Bees are booming here. Some of my first swarms have swarmed three times. I never saw such a bloom of white clover, and the honey is the finest I ever saw. Bees are very numerous here now, and the question is, what will be the result if this honey flow shall continue? Italian bees for me, every time.

J. G. NORTON.
Macomb, Ill., July 11, 1883.

Large Crop of Honey.

Those who have attended to their bees in southern Ohio, have had a large crop of honey this year.

J. S. HOFFMAN.
Madisonville, Ohio, July 10, 1883.

Drone Cells.

On page 347 Mr. Wood speaks of drone brood on worker foundation. I have never had but a trifle of that work, but now the bees are changing worker to drone cells in a few small places on some of our combs. We must, in justice, admit that all worker foundation will not *entirely* control the "where and when" of drone production; but with me it does it the first year, and controls more than nine-tenths of it ever after.

Dowagiac, Mich. JAMES HEDDON.

Honey Without Separators.

Mr. L. C. Whiting says, on page 320, present volume, that he had 700 pounds of honey stored in sections without the use of separators, and 100 pounds of the honey was so bulged that it could not be crated. Will Mr. Whiting please explain whether the sections were 2 inches instead of 1 $\frac{3}{4}$ inches wide; also, were the sections placed in broad frames or in crate or rack?

GEO. H. DENMAN.
Pittsford, Mich., July 7, 1883.

An Excellent Market.

My bees were very weak in the spring, but now are strong, and are bringing in the honey fast, when it does not rain; it has rained a part of the day almost every day for 2 or 3 weeks. I have about 50 colonies, and they are swarming some, and getting ready for the linden, which will come here about July 25. I sell all the white honey I can get by the 100 pounds in bulk, for 15 cents per pound. This is as good a market as I want.

A. GRIFFES.
Mount Bridges, Ont., July 9, 1883.

Special Notices.

Articles for publication must be written on a separate piece of paper from items of business.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

Do not send coins in a letter. It is dangerous and increases the postage unnecessarily. Always send postage stamps, for fractions of a dollar, and, if you can get them—one-cent stamps; if not, any denomination of postage stamps will do.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 50 cents; per hundred, \$3.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

CHICAGO, ILL., JULY 25, 1883.

No. 30.

THE AMERICAN
BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Rectangular vs. Square Frames.

In this issue of the BEE JOURNAL, will be found two articles on the advantages and disadvantages of square and rectangular frames. The former finds an able advocate in Dr. E. B. Southwick, of Mendon, Mich., while the latter obtains competent support by the pen of Mr. G. W. Demaree, of Christiansburg, Ky. This is a good way of ascertaining the strong as well as the weak points of each shape of frame; and, in order to bring out the full arguments on each side, we shall allow *one* more article to each advocate, and then the matter will be left for the readers to decide, individually, as to which is the best frame for all purposes.

We do not intend to take any hand in the *argument*, at this time, for these two gentlemen are quite equal to the task, and will do justice to the subject. But a few remarks of Dr. Southwick, on page 369, bearing on the editor of the BEE JOURNAL, demands attention. The Doctor remarks as follows:

"I think that the editor of the BEE JOURNAL is as unfortunate as Mr. Doolittle, when he tries to excuse Mr. A. I. Root for such assertions, but I suppose he wanted to keep up the reputation of the editors for truth and veracity. I really believe that not one-fourth of those that use movable frames, use what is to-day considered the Langstroth frame, and that number is silently growing less in proportion."

The point in controversy is the statement said to have been made by Mr. A. I. Root, that "more Langstroth frames are used than all others put together." We certainly did not intend to offer any excuse for Mr.

Root, or any one else who might make a statement similar to the above, for its *correctness* is certainly its fortification. Two years ago, just after the close of a very disastrous winter for bees, the editor of the AMERICAN BEE JOURNAL requested its readers to send in reports of how their bees were prepared for winter—whether they were wintered in the cellars, or out-of-doors; the kind of hives used, etc. From these reports a statistical table was prepared, and one of the facts brought out, was that "more shallow frame hives (Langstroths) were in use than all others put together." Among other remarks we then made the following:

"Those who have contended that the Langstroth hive is too shallow for wintering, will be surprised to learn that the figures compare very favorably for it. Thus the percentage of losses in all kinds of frame hives is 46; exclusive of the Langstroth hive it is 51, leaving only 53 for the Langstroth, being 8 per cent. in its favor. Again, this report records the results of wintering in 521,330 hives; 211,782 of which were in box hives, leaving 309,598 for all kinds of frame hives. Of the latter, 195,957 are Langstroth—*i.e.*, shallow frames—and 113,561 of all others combined. We really think these figures settle the matter of 'the coming frame.' Had the deep frames been shown to have the advantage, the BEE JOURNAL would have been ready to advocate their universal adoption, for it has no desire to favor any but the most successful methods, hives or implements."

According to the statistics then obtained of 521,330 hives, only three-fifths were in frame hives, and, of these, two-thirds were in the shallow frame or Langstroth hives. In other words—so far as any information has been obtained—more Langstroth (or shallow) frames are used than all others put together!!

Now, so far as our trying to "keep up the reputation of the editors for truth and veracity" is concerned—we accept the situation. Editors make mistakes as well as other mortals; none are perfect; but it is pleasant to

think well of others' opinions—to feel that they *have* a "reputation for truth and veracity." We do not endorse the opinions of Mr. Root, Dr. Southwick, "or any other man," unless they commend themselves to our judgment! But we hope never to indulge in uncharitable words or feelings against any one for a frank statement of opinion, and, hence, we shall exercise this *generosity* towards Dr. Southwick, when he states that "not $\frac{1}{4}$ of those that use movable frames, use what is to-day considered the Langstroth frame, and that number is silently growing less!" The Doctor's statement is so far from the facts, as settled by the only statistics available, that we have here an excellent opportunity to let "charity cover a multitude" of errors! The remark about Mr. Root's judging from the orders he receives for regular sizes of frames and materials, is exceedingly *thin*. If there were so many who use the square frame, some one would surely start a "factory" and supply the demand, as Mr. Root, and others, have done for the shallow frames.

The Doctor is, naturally, jolly and companionable, and we cannot think he means one-half of all that his language *might* imply—at least we choose to take that view of it,—while we imagine that we discover the same "twinkle of fun" in *his* eye that he discovered in *his* good wife's, as she removed the stings from his face, and soothed his burning temples, with her loving hands.

☞ We acknowledge the reception of a season Ticket to the Southern Exposition, to be held at Louisville, Ky., during the month of August, and also a pressing invitation to attend the Kentucky State Bee-Keepers' Convention, and though it is very difficult for us to leave the office, we intend, if possible, to be there at least for one or two days.

The Rev. Dr. John Dzierzon.

Mr. C. J. H. Gravenhorst, a celebrated German writer, has given the following sketch of the life of the greatest living German bee-master, the Rev. Dr. John Dzierzon, in the *Bee and Poultry Magazine*:

The subject of this sketch was born on the 11th of January, 1811, at Lobkowitz, in Silesia, Prussia, where his father was a farmer. Dzierzon's father was an apiculturist, and it can be rightly said: Parson Dzierzon obtained his love for bees in the milk of his mother. Even in his boyhood, bees fettered his soul. From 1822 to 1833, he studied in Breslau. In 1834 he took the office of the chaplain at Schalkowitz. In 1835 he was called as a Catholic priest to Carlsmarkt, in Silesia, where he worked in blessed activity until the summer of 1869. Since that time he has retired from his clerical duties in order to devote himself thereafter entirely to his bees. He immediately founded an apiary in the garden of the parsonage at Carlsmarkt. The number of hives here soon grew too large, and then he erected additional apiaries in the neighboring village, so that he soon had 12 apiaries, occupied by 400 to 500 hives, and they called him "the Duke of Bees, of Carlsmarkt."

In February, 1853, he introduced the Italian bee. He succeeded in propagating this race pure, and to diffuse it over all lands. At first he reared bees in ordinary hives. He invented the really most perfect habitation for bees, the hive with movable combs. After many attempts, Dzierzon built a hive not so long and higher, to make up for it, with a fixed top and floor, and a door at the side. Now he could easily take out and put in again the combs built in chambers; the hive with movable frame work was discovered, and as long as bees are reared, the name of Dzierzon must and will remain, in honor of this discovery.

By means of the hive with movable frame work, the bee became a domestic animal in the full sense of the word. Dzierzon became, by means of his hive, unlimited master of his colonies, for it allowed him an insight into the inmost portion of the life of bees, and, gifted by God, with a remarkable understanding, and with an unusual and keen observation and power of combination, he very soon perceived the wonderful life and motion of the bee hive.

Dr. Dzierzon set up a new and true theory of bees, which endured the fiery ordeal of practice and science, and in a short time became the healthy and solid foundation of a care of bees rational and conformable to nature. With the help of the Italian bees, the gifted master succeeded in silencing the last doubters of his theory, or in making them defenders of the same. His theory is briefly this: There are in a normal colony of bees, 3 kinds of creatures, queen, drones, and workers. The queen is the only perfect female in a colony; is impregnated only once in her life; and lays the eggs for all

the forms of bees. She impregnates the eggs in the very laying, or else does not impregnate them at all. In the first case, queens and workers are hatched from them, in the other case, drones. These, the males, are virgin-born, i. e., they are hatched from eggs that the queen lays unimpregnated, which she allows to pass contact with the drone sperm from her receptaculum seminis. The workers, that are hatched from impregnated eggs, are imperfectly developed female beings, which, in spite of these imperfectly developed organs, which admit of no fertilization by a drone, still under certain circumstances, can lay eggs, from which, without exception, drones only are hatched. The parthenogenesis is the doctrine of the virgin-born in the bee hive.

Dzierzon's name has penetrated to all parts of the earth, and he is every where acknowledged a great master, as is shown by the great number of domestic and foreign diplomas.

Since 1848, Carlsmarkt has become the goal of pilgrimages of bee-keepers. What Dr. Dzierzon has accomplished for the cause of apiculture, can be learned from his books; but only Dr. Dzierzon himself can set the example of how we must love and investigate the bees. In no way has he done more for bee-culture than in this, that he had formed scholars, in whom his apicultural spirit, the spirit of observation and investigation, has been roused. His life remains sacred to his scholars and friends.

Kentucky Bee and Honey Show.

The Kentucky State Bee-Keepers' Association will hold its annual meeting in Louisville, Ky., Aug. 29 and 30, at the Southern Exposition building. We hope to have a large attendance of the bee-keepers of the State, and also of other States, both North and South, as the convention will be in session during the week of the Honey and Bee Exhibit. And premiums amounting to \$60 are offered by the commissioners of agriculture of Kentucky, for Kentucky honey, and \$40 by the Exposition, for the finest Italian bees in Observatory hives. The premium on bees is open to the world, and we hope to see a fine display.

The Bee-Keepers' Convention and Honey and Bee Show will be held in the same week of the great exhibition of fruit, for which over \$2,000 in cash premiums will be paid.

We extend a cordial invitation to all bee-keepers' societies, to editors of bee publications, to honey-producers, and queen breeders, and all who are interested in apiculture, to be with us. We hope to have the father of modern bee-keeping with us, the Rev. L. L. Langstroth, to whom a cordial invitation has been given.

Reduced fair on all railroads, both North and South, will be offered to all who attend the Great Southern Exposition. It will doubtless be the grandest exposition ever held in the United States, in magnitude, and nearly equal to the Centennial.

N. P. ALLEN, Sec.

The National Convention.

The National Bee-Keepers' Association, will hold its Annual Convention in the City Hall and Council Chamber in the city of Toronto, on Tuesday, Wednesday and Thursday, the 18th, 19th and 20th days of September, during the second week of Canada's Great Fair. All the railroads in Canada will issue tickets during this week, good to return, up to Saturday night 22d, at single fare for the round trip. Special excursion rates will be arranged from various parts of the United States, of which due notice will be given. Those who intend being present may be kept posted on the latest excursion rates, etc., by addressing me, and also that I may arrange hotel accommodation. Private lodgings will, if possible, be secured for those who desire it, and every effort will be made to make everybody comfortable. A grand meeting is anticipated.

D. A. JONES, President.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL.
Monday, 10 a. m., July 23, 1883.

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—Extracted honey commences to come in freely, and a large crop is reported from all quarters. The demand is very good, and keeps pace with the arrivals. For choice extracted honey I pay 70¢ per lb.; the latter price for choice clover. I have received several nice lots of comb honey, for which we paid 15¢ to 16¢ on arrival.
BEESWAX.—Arrivals of beeswax are plentiful. We pay 32¢ for a good article on arrival.
CHAS. F. MUTH.

NEW YORK.

HONEY.—Best clover in 1-lb. sections (no glass) 20¢ to 21¢; in 2-lb. sections (glassed) 18¢ to 20¢. Fair quality, 1 and 2-lb. sections, 16¢ to 17¢. Extracted, white, in small barrels, 10¢ to 11¢; buckwheat, 8¢ to 8½¢.
BEESWAX.—Is more plentiful. Prime yellow sells at 36½¢.

H. K. & F. B. THURBER & Co.

CHICAGO.

HONEY.—New crop of comb honey is being offered, and some sales of it have been made at 16¢ to 18¢ in 1 and 1½ frames. The receipts of extracted are liberal, and there is a good deal of complaint about unripe honey; consumers holding off. Market, 16¢ to 17¢ for white. Very little dark left, and some inquiry for it.
BEESWAX.—30¢ to 35¢.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY.—New extracted is arriving freely—selling for 7 and 8 cts. New comb coming forward slowly; extra white, 16¢.
BEESWAX.—No beeswax in the market.
STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY.—Some new comb jobbing at 14¢, but old do nominal. Only a few barrels of extracted and strained sold within quotations—6½¢ to 7½¢.
BEESWAX.—Sold irregularly from 32¢ to 34¢—mainly at 32¢ to 33¢.
W. T. ANDERSON & Co., 104 N. 3d Street.

CLEVELAND.

HONEY.—New honey has begun to come forward and with it a demand has sprung up. New white 1-lb. sections sell 18¢ to 20¢; 2-lb. more slow 17¢ to 18¢. Old 1-lb. white, 18¢ to 19¢; old 2-lb., 15¢ to 16¢. Extracted has sold better lately, and all old stocks have been sold out at 8½¢.
BEESWAX.—Not offered.
A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY.—Our market is fairly active. We quote: ½ lb. sections at 30¢; 1 lb. sections, 22¢ to 25¢; 2 lb. sections, 20¢ to 22¢. Extracted, 10¢ per lb. Good lots of extracted are wanted in kegs or barrels.
BEESWAX.—Our supply is gone; we have none to quote.
CROCKER & BLAKE, 57 Chatham Street.

CORRESPONDENCE

For the American Bee Journal.

Transferring—The Old vs. the New.

JAMES HEDDON.

By transferring, I mean permanently changing colonies from box or unsuitable hives, to better hives of other dimensions. Full and explicit directions for manipulating the old method have been so repeatedly given that it seems quite unnecessary to go over the ground here. We have been told all about how to cut open the box hive; how to cut out the combs; to brush off the bees; lay the combs of brood and honey down on to a board covered with woolen cloth; lay the frames onto the combs; cut the combs snugly inside the frame; slip the frame snugly over the comb; tie a string around the same, or tack on some sticks or clamp on some clamps, etc., etc., etc., and when the frames are filled, "hive the colony and the work is done."

The objections to such a plan are these: The different devices for fastening comb do not succeed in holding it in place at all times, especially if put in, in pieces. If not put in in pieces, the ordinary box hive and most worthless frame hives contain scarcely comb enough to fill three frames, and piece work forever after looks, and is bungling. More or less brood is destroyed; honey is leaked and daubed about. A colony thus transferred is not worth as much to me by several dollars as one transferred by the new method.

The old method of cutting out combs and fitting into frames, is entirely obsolete here. With our modern advantages such a course is far inferior to the one I am now going to describe. First, let me say that I considered it a great error to hive a swarm of bees upon other than straight all worker combs, or full sheets of comb foundation, securely stayed, which will be these combs in 48 hours.

When we are buying bees we prefer combs naturally built in empty frames, to those that are transferred. Again, we very much prefer combs drawn from full sheets of foundation to either. No matter how nice the combs may be in the hive I transfer from, I proceed as follows:

About swarming time I take one of my Langstroth hives, containing eight given pressed wired frames of foundation, and with smoker in hand, I approach the hive to be transferred. First, I drive the old queen and a majority of the bees into my hiving box. I then remove the old hive a few feet backward, reversing the entrance, placing the new one in its place and run in the forced swarm. In two days I find eight new straight combs with every cell worker, and containing a good start of brood.

Twenty-one days after the transfer, I drive the old hive clean of all its bees, uniting them with the former drive, and put on the boxes, if they are not already on. If there is any nectar in the flowers, the colony will show you box honey. About the queens: I usually kill the forced queen as the bees run in.

I run them together as I would one colony in two parts. Now to the old beeless hive; of course there is no brood left, unless a little drone brood, and we have before us some combs for wax, for more foundation, and some first-class kindling wood.

If you have no method by which you can use a full hive of frames, of full sheets of foundation, running a full swarm into them at once, by all means procure it without delay.

But if any one has a mania for cutting up combs, and fitting them into frames, by method given above, does not prohibit them using all the straight worker comb the old hive contains, after first extracting the honey from them. Should any one wish to increase his colonies at the same time they transfer, the following deviations from the above are only necessary. Run the second drive into another hive of full frames of foundation, and use the old hive as before.

Now, that we have got foundation perfected, so that the bees will draw the lines or side walls to full breeding depth, in from two to three days, why fuss with the old comb from the old hive?

Having once experienced the above method, I shall never go back to the old one. All of you know what a nuisance a few odd sized hives are in the apiary, also some who have just started, wish they had adopted some other style of hive. The above method of transferring, will, in my judgment, get all such out of their trouble.

The cost of foundation, and new hives, is fully made up by the better combs, and you have the change to better style of hive, thrown into the bargain. I have thoroughly tested the results of the plan herein described, and am speaking from experience.

My method of fastening securely full sheets of foundation, is by making it in wired frames with the Given press. Those who have but very few colonies and consequently cannot yet afford a press, can wire their frames and hand press on ready made comb foundation.

Dowagiac, Mich.

For the American Bee Journal.

Bee Items from Australia.

A. VERGE.

In the expectation that some reader of the BEE JOURNAL may be able to advance a reason, I ask the question, why do bees worry and throw out their hatching brood? I began the season of 1882 with 11 colonies, in Langstroth hives, and, not desiring increase, I attempted to prevent it by removing frames of brood to less vigorous colonies, and cutting out queen

cells; but the bees appeared dissatisfied with such arrangements, and did no work in the sections. They continued the process of queen cell building, and whenever a colony became populous enough to work in the sections, then also occurred afresh a desire to swarm. However, I continued to cut out cells, and remove brood, till the season had advanced so far that it was very certain swarming must be over for the year.

From January 1st to the end of February, showers of rain fell almost every day, and during all that time and afterwards they employed themselves with worrying and throwing out the hatching brood. To such an extent was the destruction carried on, that I had to unite colonies, and now I have only three which were left strong enough to store sufficient supplies for the winter. The dead bees cover the ground below each hive; in some cases over a space nearly 15 inches square, and in the middle to the depth of an inch—the odor from them being quite disagreeable at a distance of several feet.

At first I thought it might have been brought about by my having checked their desire to swarm, but I noticed that the bees in each of the four common box hives in another part of my yard, were engaged in the same way. Then I concluded that, owing to the rainy weather, the store of honey which they could collect was insufficient to supply the wants of so much young brood, and that they took this course as the surest way of checking the drain upon it. But, as there were thousands of acres of white clover immediately around, and any quantity of flowers from forest trees, with no other colonies within 3 miles to share the supply, I find it difficult to believe that so few colonies should have been unable to collect sufficient for themselves.

In order to increase the honey resources of this place, I have introduced several bee plants. Besides a few rows of white sage and horsemint, I have a small plot of catnip and sweet clover, the produce of seed supplied in January last by Mr. A. H. Newman. These are growing most luxuriantly on river-bottom land, while some that I tried on hill-land with a stiff clay sub-soil, at a depth of 12 inches, did not thrive at all; in fact, in spite of continual waterings, there are not now to be seen more than half a dozen wretched plants, about 3 inches high, out of a plot of 12 feet square. I think it pretty certain that in this region, sweet clover will require the same depth of soil as does lucerne (*alfalfa*). Of course it would grow on a poorer soil, but it could not produce much stalk or flowers. My trial, however, was somewhat severe, because in a soil not deeper than 12 inches, and under our summer sky, no sufficient moisture, in spite of frequent surface watering, could be present below the top for the nourishment of the plant while tender. Probably if planted on the same kind of land in the fall, it would gather strength enough before the following summer to withstand a long period of dry weather.

I shall have other opportunities, I hope, of reporting upon it; in the meantime I shall plant it upon bottom land, and though in such soil it grows so rapidly as to justify a little apprehension that it may really merit the appellation of "weed" bestowed upon it by some bee men, yet I think it can hardly become such a nuisance as are the worthless weeds which annually overrun these lands, and from which it seems to me, there springs at intervals of time, new varieties of vegetable pests never seen in previous years.

For the American Bee Journal.

The Best Size of Frame.

E. B. SOUTHWICK.

MR. EDITOR: As I understand that my proposal concerning a "standard frame" has been accepted, I will proceed to fulfill on my part. As a preliminary, I will give the difference in reliability between theory and experience.

Theory founded by correct reasoning from scientific or known facts, always works the same under the same circumstances, while experience only shows what has been done once, not knowing what may be the real cause, but is no sure guide to what may be done again. For example: One year I learned by experience that I could break up a laying worker by dividing the colony and giving each part a ripe queen-cell. The next year I learned, by experience, that I could not do it. We find, especially in bee-keeping, that we learn many things by long experience, that we learn afterwards are incorrect. Experience shows us consequences without causes, while properly formed theories show us the bottom facts. In forming my theory of frames, I intended to use such facts as are well known to every bee-keeper.

Concerning frames and what they are called, I will say I think that Langstroth's inventions included all frames that were made separate from the hive and separate from each other, and consequently movable. So to Langstroth belongs the honor of inventing the movable-frame, whatever size it may have, but when he put out his book, he made a certain size his frame, others made a certain size their frame, so they came to be called each size after the man who first used or chose them, thus Langstroth's frame, Gallup's frame, etc., while they are really all the Langstroth frame. In this article I shall only consider the square frame in comparison with the long and shallow one, without regard to size.

The first object of bee-keepers and bee-keeping is to rear bees fast, and fill the hive with bees, at the proper time, in the quickest time possible; the second, is to get the most honey, and in the best marketable shape, and third, to comfortably and successfully winter them.

It is a well-known fact that the largest amount of matter can be pro-

duced by the least amount exposed on the surface, in a perfect sphere. The bees are philosophers enough to know this, for, when there is no obstruction in the way, and they desire to protect themselves from outside exposure, they assume that form, and in the centre of that sphere they commence to build their comb, and there they commence rearing their brood, and from this centre they extend their comb-building and brood-rearing in every direction, keeping up the same spherical form, as nearly as possible, depositing their honey and pollen close outside the brood nest, where it will be convenient to feed; and when it is fed out and more eggs are deposited, more honey and pollen is deposited outside of them. And so it goes on, until the capacity of the queen is reached.

Now, if we place obstructions anywhere, so as to prevent their working in this spherical form, we retard their progress, by crowding them in some other direction, and thus exposing a greater amount to the surface, and obliging them to retain more bees at home to keep up the extra heat and do the extra work that they would have to do, in cleaning and waxing up the extra surface they would have. All this extra retention and work is brought in when their best effort should be put forth to rear brood and fill their hive with bees. Need I say that a square frame, and just enough to make a cubic space, is the best? Cannot any person with half an eye see that no frame with right angles can be as good as the square frame.

Now, for the second object: The bees in the square frames have their room filled with brood, but they have some room in the corners of the frames to put in honey and pollen for the brood, and as that is over some part of this sphere, it is always warm, the wax is easily manipulated, the comb is quickly made and filled, and they are ready to go into the sections with honey alone, for they have deposited pollen below for the brood.

In the shallow frames the bees have been crowded out of their natural sphere at a loss, as I have shown, of heat, labor and brood, and the honey and pollen they now bring in has to be stored at the ends of the frames, for the brood goes to the top, and as it is much cooler out there, it will keep more bees from the field or other work in this part, to keep up the heat so as to enable them to work the wax and make comb, and their work must go on much slower than in the square frame, and if kept without the sections until filled up, they will be found to be much behind those in the square frame.

But we will put on the sections. The bees from the long frames go in with a rush, frequently deserting the ends of their combs; and as they find a chance to restore the equilibrium of their sphere, they go to work with a will, making combs in the sections, filling them with honey and pollen, and the queen entering into the spirit of the rest, walks up their and deposits her eggs, thus spoiling many sections of fine honey. I have heard shallow-

frame men say that queens did not bother them that way, but when I hear one of them inquire of another how he keeps the queen out of the sections, and find thousands of those zinc bee strainers—I do not know what else to call them—advertised and sold, I conclude the queen does go up; and if she is kept down by that zinc honey-board, it does not prevent the bees from depositing pollen in the sections which is nearly as bad as brood. When the sections are put on the square frames, the bees go into them as they require the room, and as they have room near the brood for the pollen, they seldom deposit any in the sections.

It is claimed for the shallow frame hive that it is better for comb honey. Let us see, I have shown that there is not as much heat accumulated in the shallow frame, and that they require more. The square frame would have much more heat to spare, and, consequently, would warm more room than the shallow frames; and on our tiering-up principle, I have never found any trouble in getting bees to go up, if it is only warm. Considering all the facts in the matter, I can but conclude that a proper arrangement over the square frame hive is better than an equally good arrangement over a shallow frame hive; besides, the sections over the square frame, if the arrangement below is right, are seldom visited by the queen, or any deposits of pollen are found in them.

The last object is to winter the bees successfully. The same reasons why the square frame is best for brood-rearing are equally good for wintering. The power to economize heat, and a chance to go into a natural spherical position, is all a frame can do toward wintering, and as the square frame does that, and the shallow frame does not, the square one must be the best for wintering. I will notice a few of the reasons given for using the long, shallow frame:

"Bees occupy the sections sooner." That is so; but I think I have shown that to be a fault, for the work done early in the sections ought to be done below, that the sections filled by prematurely entering them, and many more, are spoiled by brood and pollen.

"Bees have less distance to go to get to the sections." Let us see; take a frame 12 inches square, and you have 24 inches by the frame to the farther section on it, then cut the frame horizontally in the middle, and place the top half, back of the lower, and you have 30 inches, by the frame, to get to the back section. How is that for distance?

"The Langstroth frame is the most economical." Every one knows that it takes less material to go round a square, with equal sides, than one with unequal sides, both containing the same number of square inches.

"A majority of men that keep bees use it." This, in itself, would be no reason, if it were true (we all know that all our improvements have started with a minority), but I am satisfied that it is as false as I have shown the other reasons to be, for I have taken much pains to inform myself, when-

ever I have met bee men, whether in convention or elsewhere, and I have come to the conclusion (mind I do not state this to be a fact, as our Langstroth frame men have what they have said about it; and let me here say that when a man makes a statement for a fact, which he does not know to be a fact, I consider it but little better than though he knew it was false) that not one-eighth of the bee-keepers of the United States and Canada use Langstroth's frames, and when I say Langstroth's frame, I mean both of those sizes, that $\frac{1}{4}$ inch of which has taken up so much room in the BEE JOURNAL.

I think the editor of the BEE JOURNAL is as unfortunate as Mr. Doolittle, when he tries to excuse Mr. A. I. Root for such assertions, but I suppose he wanted to keep up the reputation of the editors for truth and veracity. I really believe that not one-fourth of those that use movable frames, use what is to-day considered the Langstroth frame, and that number is silently growing less in proportion.

Occasionally we find a man changing to that side, probably because he thinks he is getting on the popular side. Mr. A. I. Root boasts that he has obliged some one to adopt the Langstroth hive, not because it is the best hive, but because he cannot get supplies for the best one.

The many letters I have received asking for samples of my hive, some from men who have the Langstroth hive, and my observation generally convinces me that the "blow" is over, and the swells are becoming gradually less, and the undertow will eventually carry the Langstroth hive all out to sea.

I would not wish to convey the idea that these men wish to misrepresent or state anything not true, for I think they believe all they state, and the reasons are these: They make and keep on hand the supplies for the Langstroth frame and hives, and say "if you want any other you must wait until we can make them." The result is, that those who use others than the Langstroth frame supplies, either make their own, as I do, or send elsewhere for them, and the very few orders that A. I. Root gets out of the vast amount used, not of the Langstroth frame class, causes him to say, "More Langstroth frames are used than all others put together." Judging probably from the orders he gets, I presume that it is from them he judges, for I have about concluded that he sometimes thinks that himself and customers are all there is left of bee men. Considering his opinion was formed as above (and I can excuse him in no other way), it proves to me that the Langstroth frame is in a very small minority of the whole.

"They are so easy to manipulate." Now, I will digress a little, and give some comparative experience in the manipulation. Having a large colony in a Langstroth hive, I concluded they must have some honey to spare, so I took my tools and went out to investigate. I removed the cover and cloth from the top, and smoked them

plentifully with my big smoker, which is not of the simple or simplicity kind, such as Mr. Root hires debased men with to quit debasing and try to be somebody, but one, that after using the biggest Clark's I could find for a year, the village tinner and myself made one just to my liking. I then attempted to raise a frame of sections. I pried it one way and then the other; then tried to pry up and pried off the top bar. I placed it back, and then pried each frame separately as far as I could, from the centre one, and I crowded that one way and the other, until I thought I had it loose. By this time the bees had begun to come up. I gave them a good smoking and then took hold of the frame with both hands near the ends, and pulled steady. But it did not come, I pulled a little harder and thought it came a little; I tried again, it appeared fast, jerked a little on each end, wiggled it side wise, and by wiggling, twisting, jerking and pulling, I succeeded in raising it up, so that I could see there was some very nice honey in the sections. This gave me new courage, and I went at it with renewed strength. Just at this time an investigating bee struck me on the nose. I looked for my smoker. It was sending forth a stream of smoke sufficient to engulf the whole colony in five seconds if I could have directed it; but I could not. Both hands were engaged, and if I let go I would lose all I had gained. But I was not to be beaten out by one bee, so I wiped him off on my arm and continued the jerking, but as the bees came out thicker and faster, and all appeared to come directly for my face, and sting immediately on arrival, my thoughts were soon turned, not "on peace," but "war to the knife," until I subdued the bees. I dropped the frame, it went down with a thud; I seized the smoker and gave them such a charge as sent all back to the hive or somewhere else, that were not busy on my face trying to pull out their stingers. I covered up the hive and left for the house. I did not swear, but I said "Oh, my," frequently; and when I got into the sitting room, and threw myself into the big chair, I uttered an "Oh, my," which gave all that heard it to understand that I was not the happiest man on earth.

My wife came in, with a tear of sympathy in one eye and a twinkle of fun in the other, and commenced to do what the bees, in their hurried departure, neglected—to take out their stingers. She got out all that she could find, bathed my face with ammonia, and advised me to go and lie down. Well, I have long since learned that it is sometimes better to take my wife's advice (but I never own it). So I laid down and there considered the great pleasure and ease in manipulating bees in the Langstroth hive, and after concluding that if I could find a man fool enough to invest 5 cents in such a hive with at least 50 pounds of honey, I would dispose of that colony. The pain decreasing as the swelling increased, I soon went to sleep. Oh! blessed state

of unconsciousness. When called to supper, I was enabled by rubbing, pricking and punching to get one eye open so as to find my way to the supper table; and I sat down a perfect laughing stock for the whole family, which amount to only ten when no outsiders are present. Well, I got over it; but not so with the bees, for I called to my aid some of that stuff the good old minister used to use to make us boys good, "fire and brimstone," and with it silenced the bees, took away the honey, and with an axe, made kindling wood of the hive.

Again, I started for the apiary, took my tools, and this time went by the way of my wife's flower garden. She was there pruning some, and enjoying their beauty and fragrance. She asked me to go in, but no, I was in a hurry going to work at the bees, and observed, I thought there was too much time spent already with flowers. Yet I lingered until she picked me a small bunch of sweet scented roses and tied them together with some striped grass, and as she handed them to me said, "Now hurry along or you will spend too much time with the flowers." I took them, feeling a little rebuked, but said nothing.

As I passed along, I took up a stool that I use when a little lazy, while over-hauling a colony. I went to one that I thought had some honey to spare, sat down on my stool at the back of the hive, took another sniff at my flowers and laid them down on a hive to my right, removed the cover and cloth from the one before me, blew a little smoke into the top, just enough to inform the bees that I was there, then removed the back end board of the upper or section-honey department of the hive. The first frame of sections was not all capped, so I took it out and put it on the grass. The next I noticed was filled and nicely capped. I also saw that they had built comb from the lower side of the section frame to the upper bar of the brood frame. I took my long knife, that I use in uncapping, and cut it loose, close to the section-frame, then with my left hand took the frame back and out, and with the thumb nail of my right hand, pushed off the separators (these are the separators that Root and Miller told me would not stay. Well, if I used the Langstroth hive, I should want them spiked on, and the section frames bolted together, but I do not). I put the frame down on the ground, to let the bees fly off, and in the same way proceeded to take off four more frames, which were all that were capped over. I then cleaned off the comb the bees had built between the brood frames and sections, put in five new frames with new sections containing white clover comb, that I had made to order by the bees last fall for starters, and the same separators that were on the others, then the first frame and end board, the cloth and top, and all was right again.

I then took each frame of honey that I had taken off, brushed off what few bees remained on them,

and placed them in a box near by, for that purpose. I then took my seat again at the rear of the hive, took out the end board of the breeding apartment, took out a quantity of brood combs, cutting them loose with the knife at the sides, and found them nearly all filled with brood; so much so that the queen had little or no room to lay. This would not do. They would swarm and thus stop the surplus honey gathering. So I selected three combs with brood and bees, examining them closely, to see that the queen was not on them, put them to one side, and filled the space they occupied with new frames of foundation, made on the Given press and nicely wired in, not with wires from upper corners to centre of bottom bar crossing the upright ones as in Langstroth frame, but with upright ones alone.

All were taken out and put back with one hand, holding the smoker in the other, ready to give any bee that showed fight a puff. Well, they were put in, and the hive closed, by putting in the end board. I then took the three extra frames of brood and bees in one hand, and the smoker in the other, and went to a hive where I had put in half a dozen similar frames before, put them in and gave them all a good smoking, and then went back to my stool, took up my bunch of roses, and as I sat there noticing the different speed with which bees leave and return to the hive, and sniffing at my roses, the supper bell rang, so I gathered up my tools and started for the house as happy as a president.

One thing more and I have done—persuading all to use one size frame and the benefit of the same. I would as soon undertake to unite all religions under one creed as to unite bee men in using one size of frame; and anything so very improbable, it is folly to undertake. It would be some benefit to the dealers in supplies and bees, but very little to the honey-producer. For instance: A man has more colonies in the fall than he wants. He, perhaps, could sell them if his frames were right for \$6, but it is seldom he can. If he killed his bees, his hive would be worth \$2, the combs \$1, and the honey that would go with them, when extracted, at least \$4 more; so he would really lose \$1 in selling. But right here some tender-hearted brother or sister will raise their hand in horror at killing the bees. Is it worse to kill them than to let them die through neglect or ignorance? I will relate a little circumstance to illustrate. As I was killing some bees I did not want, a very good man was present. He told me it was all wrong; that after they had worked for me all summer, then to kill them, it was wicked, and the sin of it would come up against me hereafter. I said nothing, but waited my turn. A few months after, I was at his house. He was butchering a cow. I asked him how old the cow was. He replied that she was 17 years, and that she had been the best cow he ever saw; that she had furnished his family milk and butter for 15 years—my time had come. Says I,

deacon, will you, after a cow has helped you support your family for 15 years, now kill her and eat her up. It is awful: it is wicked, and it will come up against you hereafter. He said he would have to give in to my "right of might, for self-preservation."

Mendon, Mich.

For the American Bee Journal.

Square vs. Shallow or Deep Frames.

G. W. DEMAREE.

The movable frame is not a "fixture" in the sense that the apiary house, and the hive or tenement of the bees, are fixtures. The movable frame is simply an implement employed in the hive or tenement to manipulate the inmates of the hive, and to aid in the production of honey.

Viewing the matter from this standpoint, there is no great probability that any one particular form or size of frame will ever be accepted as a "standard frame" by the great mass of bee-keepers scattered all over the American continent, so varied in climate, as well as in other respects bearing on the occupation of bee-keeping. The facts show that there is an unlimited number of sizes of the movable frame in use, yet there are but two "forms" of this greatest of all the implements of the apiary, viz.: the Langstroth shallow frame and the square or deep frame. The issue to be described in this controversy is, which of these two "forms" is best adapted for all purposes in the culture of the honey bee, and in the production of comb and extracted honey.

I unhesitatingly take the grounds that the Langstroth or shallow frame carries with it more good "points," and is, therefore, better adapted for all purposes as an implement in apiculture than any frame yet invented. I regret that in presenting the evidence in behalf of the Langstroth or shallow frame, it does not go before an impartial jury as a whole. Some have already made up their decision, while others are moved by self-interest and prejudice, nevertheless there are many fair-minded apiarists who can appreciate facts and arguments, and to such I appeal. In the first place the size and shape of the frame used will necessarily govern the form and size of the domicile in which the bees must reside and carry on their handy work. I regard this as matter of much importance. The Langstroth or shallow frame is adapted to a hive with a low, broad brood-chamber, which gives a broad and firm base or foundation to the hive, such a hive sits firmly on its stand, is less liable to be over-turned or shaken by high winds, is less easily jarred, admits of two or more stories without becoming too tall and slender in proportion to its base, as is necessarily the case when a square deep frame is used. Such a hive looks better; proportion is always pleasing to the eye, and is better for all purposes for the reasons given than the tall, slender, bee-gumish looking hive which must be con-

structed to accommodate the square or deep.

MECHANICAL CONSTRUCTION.

The Langstroth frame being shallow, is more easily made square and free from wind than a deeper frame is. A little "winding" in the frame does not effect its position in the hive as is the case with a deep danggling frame. The hive itself being shallow, will vary less by slight mechanical inaccuracy, and if the old-fashioned porticos are left off, as I would advise in all cases, the hive is the most simple in mechanical construction.

THE BEE HIVE AS A DOMICILE AND WORK SHOP.

The bee hive answers the two-fold purpose to its inmates, for a residence and a factory or work shop. The Langstroth frame as an implement of manipulation for the convenience of the bee master, and to put the internal working of the hive under his control, admits of a structure best calculated for these purposes. Its broad base admits of free circulation of fresh air; every part of the lower floor is handy and convenient to the work going on above. The stories of the hive being low, less distance must be traveled to reach the highest part of them. The honey bee is the most sensitive of all creatures to the slightest jar, and no form of hive protects them so well from this annoyance as the Langstroth hive with its broad base and low stories. For this reason the combs are less liable to be fastened together with cross ties of wax, and propolized at every point.

A low brood-chamber, if the cover to the hive is double with an air space between, as they should always be in winter and summer, is less effected by the heat of the summer sun than a tall one is. I have never seen a single comb that had been injured by the heat of the sun in a Langstroth hive, while I have seen, in transferring from tall box hives, many outside combs that had been melted down by the sun's heat. A low brood-chamber is best adapted to the "tiering up" system of manipulation of bees for the best results. No one will deny that the Langstroth or shallow frame is best adapted for this purpose. Some apiarists tier up the Langstroth hive to three stories or more to accommodate large colonies.

Now, let us take a practical look at the two "forms" of hives which must be used to accommodate the two "forms" of frames.

The Langstroth hive, if tiered up to three stories, is 20x16½ inches on the stand, if made of 1 inch boards, and 30 inches high if we allow 10 inches for each story. Of course I do not pretend to speak accurately here as to measurement. It will be seen that the Langstroth hive, even when three stories high, is quite well proportioned as a building. Now let us look on the other picture. A hive made to accommodate the square frame in ordinary use, is about 14 inches square at the base, and if tiered up three stories high, will be at

least 3 feet in height. Of course such a hive is out of all proportion. Some may not wish to "tier up," but many of us do, and it is a question of "all purposes" we are discussing, and adaptability to the "tiering up" system is an important point in the "all purposes."

EASY AND RAPID MANIPULATION

is a matter of the greatest importance in a large apiary. Every skillful manipulator of bees who has experience with the two forms of frames in use, can appreciate the Langstroth or shallow frame for ease and rapid handling. A shallow frame is quicker removed from its position in the hive than a deeper one is. The operator can see better what he is doing to the shallow brood department. The bees are less liable to be crushed or injured when manipulating the frames, and hence less liable to become irritated by rough handling.

The queen is now readily found in a shallow brood nest; in fact it is not infrequently the case that the operator can tell just where the queen is by the movement of the bees when he first turns back the quilt.

A hive made to accommodate a long and shallow frame, like the Langstroth frame, successfully, gives a larger surface at the top of the brood nest for storing comb honey, and right at the point where bees do their best work.

A shallow frame, when used for extracting, is sooner sealed by the bees when full of honey, *i. e.*, the bees will seal a given number of square inches sooner in a shallow long frame than they will or can on a deeper one. It will be admitted that bees invariably commence to seal the honey at the top of the frames. There must be good reasons for this, and I judge the reason is, that evaporation goes on more rapidly at this point, and hence the honey is ready to seal sooner at the top of the apartment. So great are the advantages to be gained by the use of a shallow frame for extracting honey—for the reason given above—I have been induced to use a large number of frames just half the depth of the Langstroth frame, and of the same length, and these are used in tiers in the upper story, and so manipulated that the full ones are kept in the top tiers where they are sealed with the greatest dispatch. So good has been the results of this system of management in my apiary that I feel justifiable in the digression, if I have digressed. So strong a point do I consider the above in favor of a shallow frame for extracting purposes, that I believe no number of good points in a deeper frame can outweigh it.

ADAPTABILITY FOR WINTERING BEES.

In my estimation too much has been conceded by the admirers of the Langstroth form of movable frame to the claims of those who advocate the use of a square or deep frame as best adapted for wintering purposes. I take the grounds that no form of frame yet invented is so well adapted to safe wintering of bees as the

Langstroth form of frame is. It needs no philosophy to make it comprehensible that a room with a low ceiling is more easily and cheaply heated than one with a higher ceiling. The brood department of the Langstroth hive has this important advantage over a deeper one. The instinct of the bees lead them to store their honey at the highest point in the hive; they do this because nature has taught them that it is the best place for its preservation, as well as the safest place from their enemies.

Now, in a deep brood nest, if the combs are well filled with sealed stores, the bees must cluster on the sealed honey at the top of the frames, or they must dwell below the warmest part of the chamber until they eat their way up to the top, and if any of the stores are left below them in their upward march, the chances are against their ever returning for it during cold weather, if the supply should be exhausted above. When bees are wintered on the Langstroth frame, the cluster moves in a horizontal direction with the spaces between the combs, and pass the entire winter in the most congenial part of the hive. Bees winter better in a shallow brood nest than they do in a deeper one, simply because their stores are located in the warmest part of the hive, and in a room with a low ceiling, which is always warmer than a room with a high ceiling.

CONCLUSION.

I wish to conclude by saying that I have given my reasons for preferring a shallow frame, gleaned from personal experience with both forms of frames in use. The "movable frame" is as much an "implement" in apiculture as the plow or pitch fork are implements in agriculture, and, hence, each apiarist should act just as every intelligent farmer acts, *viz.*: use that which is best adapted to his branch of the business to his locality, etc., always guided by the light of his experience.

Do Queens Mate More than Once?

I. P. WILSON, D. D. S.

The above question I supposed to be settled beyond dispute, and I was a little surprised at Mr. Hinman's article on page 357 of the BEE JOURNAL, claiming that queens do sometimes mate a second time.

That Mr. H. is mistaken about his queen mating with a drone after the first fertilization, I think there can be no doubt.

I will relate an incident that occurred in my own apiary, a month or two ago, which will show how easily one may be deceived, as Mr. H. doubtless has been.

I opened one of my best colonies, for the purpose of removing the queen to another colony. I found, on the second frame, that I removed a beautiful young queen, evidently about 3 or 4 days old. I felt greatly disap-

pointed, as my choicest queen had been in this hive. I said to myself, "they have superseded her; what can it mean?" To determine how long she had been missing, I proceeded to examine the comb, and found, to my surprise, that eggs and larvae were abundant. The old queen was still on duty, and I found her depositing eggs, here and there, as she quietly moved along over the comb. She was too busy to notice me or the rival queen. There was only one queen cell in the hive, and that was the one from which the young queen had hatched. Why they reared this young queen, and why the old queen did not object to the procedure is, to me, unaccountable. I removed the old queen to another colony, and left the young queen to take her place. A few days later, she mated. I saw her leave the hive, and in 22 minutes she returned with the unmistakable evidence of having made a successful "bridal trip." Now suppose I had not discovered this virgin queen when I did, but had opened the hive the day she mated, found the evidence of her just having mated, found also the eggs and the larvae, and had not discovered the old queen, I might possibly have been deceived as Mr. Hinman doubtless was.

Burlington, Iowa, July 18, 1883.

For the American Bee Journal.

Few Items from the Pacific Coast.

J. D. ENAS.

Since I wrote about the young bees dying, or rather going away from the hives wingless, etc., we had a honey spurt, and the hives are getting filled. Bees preferred to fill the combs with honey instead of having them filled with eggs. Whether sections were on or not, they would fill the combs in the lower story to the detriment of the queen. I think they must have gnawed the young bees out, as they were not completed, wings not half formed; some were more perfect than others. No matter how often the bees were placed on the bottom board, they would go away from the hive. If they were put in at the top, they would soon be at the entrance. On one hive I had Root sections at the sides, not commenced on, two empty combs for eggs, the balance filled with brood and stores, but they preferred to fill the empty combs with honey, instead of letting the queen fill them with eggs, and would not go into the side sections, though they all had starters. I removed the side sections and gave more empty combs, and they are satisfied for the present. There are no more young bees crawling.

I saw a laying worker in the act of laying, to-day. I have a young queen in a hive that should have young bees hatching, but she is backward. To-day, on looking for her, I saw a worker, with its head in a cell, sipping honey, and from it came an egg just like as though it came from a queen. I watched it until the egg dropped on to the comb. I caught and caged her before she could es-

cape. 'She is a laying worker. I looked and saw no more. I think there are probably more, and that they have bothered the queen in her duties. The queen looks glassy, and very much the color of old robber bees.

I shall send the bee to Prof. Cook, with an insect that I caught killing bees. I have seen a second of the kind, but had nothing to save it with, and I would not like to put my hands to it. It is a regularly savage and blood-thirsty insect. I have it in alcohol. I caught it between the bur-lap covers, over the frames. It has very quick motions, and always faces the music on guard. I jumped for the bee, and it let its jaws into the bee's abdomen, and held it clear up in the air, and was walking off with it, when I stopped it. There must be more of them.

Queen-rearing has not been profitable this season, owing to losing many after being hatched, and even after laying. On opening hives to pick out a choice queen for a customer, the young bees would look all right, but the queen would be missing. The hive and colony would seem all right, though sometimes there would be no eggs, but cells. I handle bees carefully, not to kill bees nor queen in moving frames, etc. It was not for want of room, nor on account of swarming, as I had but a few swarms in the air. Before June, I could not always open a hive when I should, and the bees would destroy the cells.

Our honey crop will not be large this season. Many have had no swarms nor surplus, while some have taken 60 lbs. each from some few hives. The most I have taken, so far, from any one hive is about 75 lbs., most of it extracted. My bees increased from 23 to 72; have sold at different times, and now have 90 of 10 frames each, all strong and in good condition to stand the season of drouth, which will soon be on us in this vicinity. We had two days 102° in the shade. One day I thought all of my bees would swarm at once, but I raised the front, and in a short time the bees were all in their hives.

Napa, Cal., July 4, 1883.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

In reply to several inquiries, let me say, that valuable queens should never be introduced to colonies having long been queenless. They should be introduced in introducing cages, which we make by wrapping wire cloth around a stick one-half by seven-eighths of an inch, and usually make them 4 inches long, with a plug in each end, and in such a manner that no wire points come inside the cage.

Diseased Bees.

I have got a colony of bees that I do not understand; they are bloated up so, and some of them get black; they lay around the entrance of the hive and die off very fast. I tried Mr. Hicks' cure for the disease, but it did them no good. They are Italian bees. I changed hives with them; the combs are clean and they have lots of brood.

JAMES GARDINE.

Ashland, Neb., July 16, 1883.

ANSWER.—I would have to see more of the phenomena you mention to give a satisfactory answer.

The colony may be robbing, and becoming demoralized, and so daubed with honey as to turn jet black. I am rather of the opinion that is the cause of the trouble. Follow up and see if you can find where they are at work.

Getting Straight Combs.

You say I will be "as successful as any one in getting straight combs if I manage properly." Please explain your method.

W. B. DRESSER.

Hillsdale, Mich.

ANSWER.—I think that my success in getting combs built in sections so straightly that no separators are needed, is the result of the following conditions:

1. I use full size pieces of foundation, and such foundation as bees draw out readily, rather than build on to, perhaps beginning on one side and getting away ahead of the other.

2. I put these pieces into the centre of the section with that invaluable little implement known as Parker's comb foundation fastener, and it stays where I put it.

3. I place the hive plumb from side to side, and thus the foundation hangs true in the section.

4. I place all my hives declining toward the front.

5. The combs in my sections run parallel with those in the brood-chamber.

6. The narrow pieces of the sections are that width that the bee passages are $\frac{3}{8}$ instead of $\frac{1}{4}$ inch, as is commonly used. This point is otherwise very advantageous.

7. The slats of my honey board are so arranged over the spaces between the top bars of the frames of the brood-chamber that bits of comb built up from said top bars cannot prejudice the bees in regard to crooking or side bulging the combs in the sections above.

8. The more of the brown German blood your bees possess, the quicker, whiter and straighter will they build comb.

Drones Variouslly Marked.

On page 344, BEE JOURNAL, Mr. J. O. Shearman asks me to answer the following: "Can a queen breed two kinds of drones at the same time? Or would it be called an indication that there might be two queens in a hive to see drones like pure Italians and pure blacks living together by the hundreds?" I do not know just what to credit to the word "kinds." Often drones go into neighboring hives and habit them the rest of their peaceful life-time. Then we see two kinds in a hive; but we often see the same "kind" of drones variedly marked, and I think such variations are much more radical among the drones of cross-breeding than among the workers. Many times I have seen drones that showed scarcely any yellow, side by side with brothers that were very yellow. Cross-breed bees are much more regular in action than in color.

Completing the Sections, etc.

Will you please answer the following through the "What and How" department of the BEE JOURNAL:

1. What per cent. of the whole number of sections used in your apiaries, during an average season, do the bees naturally complete?

2. Is the attempt to force the completion of boxes profitable?

3. What method do you use to accomplish that end when thought desirable?

4. What disposition do you make of sections partially filled?

FRANKLIN P. STILES.

Haverhill, Mass., July 13, 1883.

ANSWERS.—Let me say that the foregoing questions, I believe, are asked by a practical honey-producer of clear understanding.

1. As we never, at any time, allow our bees to become crowded for room, in the least, we have about one-third of the whole number of sections used during the season not sufficiently completed for market, when the season closes in September. We know that a different system of management would complete nine-tenths of them, but under such a system that nine-tenths would weigh no more pounds than our two-thirds.

2. I think it is generally understood that the attempt to force the completion of boxes has not been made a success, in the light of profit and loss.

3. We have never tried it.

4. When we remove our sections in the fall, we sort them over, and those not sufficiently capped to be readily merchantable, we uncapped all the cells

that may be sealed; place them in a broad frame made for the purpose; hang them in the extractor, and throw out the honey, putting the sections of drawn comb back into the case, and put them away for next year's use.

In the fall, after extracting sections when recasing the sections of empty combs (as we use no separators), the combs are not always perfect in the frames; when we find one side a little fuller than the other, we put the two full sides together, and the hollowing sides together. No matter if the full sides of the combs should touch each other, when the bees begin operations the following season, they will cut right through, building out the other sides equally, and the occasional crooked ones are thus made straight.

In reply to several inquiries received of late, allow me to append the following:

1. How to get the sections out of Heddon's cases.

This troubled us very much the first few days after using the case, but now we can remove the sections from our cases two or three times as fast as from any other arrangement. We invert the cases, four inches and a half above our honey table, the end pieces of the case just touching the rests made for the purpose. Now we have a solid wooden block scant 4 inches square and 12 inches long. This will readily slip through each department containing 7 sections. We hollow out one side of the block so that it will not bear any on the sections, except at the corners (the same object can be added to a block, by tacking on two little beveled strips). Lay this block across one row of sections, bring the palms of the hands down solidly and squarely on top of the block, one at each end; and the sections, block and all, will drop right through. (For a little handle, a shingle nail driven in will answer the purpose, in the middle of the upper side of the block, with which to draw it up.) Now you can slide the sections out from under the cases. This can be done in much less time than you have been reading this.

In emptying cases we usually drive all four rows of sections out, and then set the case aside. The honey will not break by the sections dropping this four inches, as they sort of slide out of their position, not having half an inch to fall.

SELECTIONS FROM OUR LETTER BOX

Two Queens in One Hive.

Last evening I saw what I have long wanted to see. I examined a hive, where I had introduced a young laying queen, some 3 weeks ago. On the first comb I removed, I found my queen all right. On removing another comb, by the side of the first one taken out, what should meet my eyes but another laying queen. Now, I know two queens can do duty in one hive. I removed one of them to another colony that was queenless.

W. H. SHIRLEY.

Glenwood, Mich., July 19, 1883.

Large Honey Crop.

Our honey crop is very large and of the finest quality. We are having a great excess of rain. We cannot thresh our wheat (it is so wet,) and we fear it will be damaged in the shock.

N. P. ALLEN.

Smith's Grove, Ky., July 17, 1883.

Illinois as a Honey-Producing State.

I believe that we are largely creators of circumstances. As time rolls on we are drifted hither and thither, often by circumstances over which we have no control. A number of years ago I became infatuated with apiculture, and the longer I engaged in the business, the better I liked it. Keittsburg, Ill., where I was located, was one of the very best points for an apiary in the country; and when my favorite occupation promised to pan out big, I felt that I was enlisted for life in the sweet work. Unfortunately for my hopes and desires, I became sorely afflicted, and while all last season I worked hard in my apiary, there was not an hour that I did not suffer pain; and when the spring of 1883 opened, I became so completely afflicted that I was driven from the field of apiculture into the uncertain pursuit of health. In my wanderings I pulled up at this beautiful little city of four thousand inhabitants, where I studied the profession of medicine 20 years ago. My health is much improved, and I have reason for believing that I shall entirely recover. But I have no bees, and although I have enquired earnestly for a scientific apiarist in these parts, I have found none. There are a few box-hive and log-gum fogies, and I found one bright light in the bee world, who insisted that the drones laid all the eggs. There is a young gentleman about 3 miles from the city who is learning scientific apiculture, and will make a success of it, I think, for he is both intelligent and industrious. I do not know whether I shall stay here next season or not, but if I recover my health entirely, I shall have an apiary wherever I may locate. I am inclined to believe that Illinois is as good a State for honey production as there is in the Union. I shall work, wherever I may be, to extend the circulation of the AMERICAN BEE

JOURNAL, for it will kill fogysm wherever it goes, and clean the cobwebs of superstition from the brains of all who read it. The JOURNAL comes to my new address regularly, and I read it with the enthusiasm that a boy does his first primer.

J. R. BAKER.

Warsaw, Ind., July 17, 1883.

Honey from Alfalfa.

In regard to California honey granulating, all the honey I have put up (some 19 tons) would candy by November or December, and some of the best became candied in warm weather. In giving a list of the principal honey-producing plants, in Cook's Manual, no mention is made of alfalfa, which is our main source of honey here. Last year 8,000 out of the 9,465 lbs. of honey which I put up, was from alfalfa. Since May 27, I have extracted 7,100 lbs. of alfalfa honey; and it is first-class honey too. P. LOUCKS.

Kingsbury, Cal., July 9, 1883.

[Alfalfa has often been mentioned as a honey producer. In the BEE JOURNAL for July 19, 1882, page 456, this paragraph occurs:

Alfalfa yields a good quality of honey, and is in bloom every month in the year; it will grow without irrigation in any kind of soil, amongst stones, on such land as cannot be cultivated. Scatter the seed plentifully during the winter months, so that the winter rains may settle it into the soil and give moisture enough to cause it to germinate; keep sheep off the ground so planted, and let the alfalfa get a start, and nothing but gophers can eradicate it. Most persons think that alfalfa must have plenty of water at all seasons of the year in order to grow, but for bee pasture good results may be had from it without other moisture than that obtained from rain.

Of course it is an oversight of Prof. Cook's not mentioning it in his Manual; he will, no doubt, include it in the next edition.—ED.]

The Honey Harvest.

Every one keeping bees think that the harvest of honey will be good in this locality. There has been some quite severe losses since the gathering of last year's crop; but the bees that stood the storms are doing a fair business at present, although we have had it pretty wet, and it continues to be so, with the heaviest of showers, and as much of the dreadful cyclone as one would wish to see, having due respect for his house, bee hives, etc. Yet we have some very warm days between these great storms, and no cold days that would be considered wholly lost to the honey bee. It is my opinion that the bees are doing well on the clovers, and in 2 or 3 weeks buckwheat will be in, then they will be "the busy bees" in earnest. It is the great event always with us in this country.

JOHN MORRIS.

Manston, Wis., July 13, 1883.

Honey Tree of India.

In December I was in Australia and saw a tree, a native of India, in bloom. Wherever I saw the trees they were covered with bees. I believe it to be the best honey tree I ever saw in any country. I have just returned from there and found the seed nearly ripe. I have made arrangements to gather seed. It is an evergreen, branches thick from the ground, grows a beautiful sugar leaf shape, although only a few years introduced into the country; I saw some nearly 30 feet high. I think it is a hardy tree and will live in your climate, and think it would be a valuable addition for bee and honey culture in America. I have lived many years in the United States.

EDWARD PARSONS.

Auckland, N. Z., June 19, 1883.

[The tree belongs to the linden family (*Tiliaceae*), so is a near relative of the most noted honey tree of our woods, the linden or basswood. It is, however, highly improbable that the tree can be grown in the United States; if so, assuredly only well South. The family is really a large one, but nearly all belong to the tropics, only represented in our country by one species.

Is it not evidence of botanical relationship which amounts to something when natives of opposite sides of the world, and in wholly different climates, thus possess similar properties? Last year a specimen of *sterculia*, introduced into the Southern States, was received for name, its honey qualities also being observed as excellent. Our linden is the nearest botanical relation of this tree too, and therefore the same remark applies.—T. J. BURRILL, Champaign, Ill.]

Bees in New York.

It is still wet here, and bees are getting little more than a living. We had a few days during which a little gain was made in the brood combs, but no work has been done in sections. I am glad to hear of good yields in other parts of the United States. Basswood will be in bloom in about a week, when I hope for better times.

G. M. DOOLITTLE.

Borodino, N. Y., July 12, 1883.

Bees Hanging Out.

Why do some of our bees lie out so much? They fill the portico day and night. We have taken the honey and given them more sections.

J. L. HARRIS.

Griffin, Ind., July 17, 1883.

[They probably find it too warm in the hive for the numerous family, or there is nothing to gather. Give them a little ventilation by placing a small piece of wood under the cover, and they will go to work all right, if there is anything to do.—ED.]

Bees in Arkansas.

I wintered 125 colonies in 1, 2 and 3 story hives without loss. They never breed much before the middle of February. On the last of March I united them down to 100 colonies. March 15 brings us plenty of bloom, but our bees never gathered much honey, on account of cold weather. On April 1, the weather turned warm and dry, and a honey flow came from willows, clover and poplar. On May 1, every hive was solid with brood and honey. I extracted from 2 story hives, from 40 to 60 pounds; on May 20, we had a cold rain; on the 21st the thermometer, at day break, was at 35° above zero; frost was reported in low land, but no damage was done. On the 24th, our bees went to work again. On May 28, I extracted again about 40 pounds, from the 2-story hives. Now I could extract again, 40 to 50 pounds, from the second stories. Bees are working well now on sumac, and horsemint begins to bloom. For the last two seasons we have had no consumers among the bees; every nuclei has been built up to a strong colony and given a surplus. This year there has not been much swarming. Extracted honey sells from 8 to 10 cents per pound; comb honey 12 cents. I cannot make a large and full report. I had a crop planted, and I could not obtain the necessary help, but next year I shall become a specialist with bees. I send you a specimen of what is called here horsemint. It blooms from July 1 until frost, and grows all over this State. It is same mint as in Texas, please name it.

FRANK THIAVILLE.

Forest City, Ark., July 3, 1883.

[It is the horsemint (*Monarda*), and yields an excellent quality of honey. It is the principal honey-producer of Texas.—ED.]

Clover Honey Harvest Over Now.

The clover honey harvest is over now, and a busy one it was. We had good weather, with the exception of five days last week, which were too hot, and killed the last clover that would have kept the bees at work a little longer. But when I look at my honey, I am well satisfied for this year. I commenced with 23 colonies; devoted 3 for experiments, and, of course, the result was, not much surplus from them. I devoted 7 for comb honey; the result was about 250 pounds, in one-pound sections, an average of 36 pounds; not a very good result. Swarming is the cause; could I control it, I could do much better. From one Cyprian colony, devoted to comb honey, I obtained 5 swarms, but only about 12 one-pound sections filled nicely, and the honey in the brood department was well used up. From one colony that did not swarm, I got 66 pounds in one-pound sections; that is the best I ever did with one colony devoted to comb honey. Give me the cross of Italian and German bees for all purposes. From the 13 colonies devoted for extracted honey, I took 85 gallons, and can easily get 15 gallons more, to make it 100 gallons;

but to do this I must take up the increase, for 25 colonies is about all I can keep here, in the city limits. But here I run against B. F. Carroll, on page 336 of the Weekly BEE JOURNAL. What does he call one who kills bees? He may say advertise and sell your queens. But I think after purchasing cages and paying postage, there would be very little left for my work. I might unite the bees, and board them until October, when they may die a natural death, from old age. Is it not strange that those standard frame advocates have not stated the greatest score against the Langstroth frame, namely standing the frame on end, when extracting?

LOUIS HOFSTATTER.

Louisville, Ky., July 13, 1883.

Bees Reveled in Clover.

Basswood is just coming into bloom. Bees have done well on white clover, considering their condition in April and May. I have now 282 colonies, and 18 more to hear from. I could not run an apiary of that size without clipping queen's wings. I have taken 70 pounds of fine honey from one hive of Italians, and think they have about 20 pounds more. I am extracting all clover honey, and marking the barrels so as to avoid mixing. I do not think it a suitable pursuit for an invalid to follow.

WM. LOSSING.

Hokah, Minn., July 13, 1883.

Honey from Dog Fennel.

Mr. Enas, of Napa, Cal., asks if honey from dog fennel is poisonous? We get a good deal of honey here from wild camomile, which resembles the dog fennel of Tennessee, which is very bitter, but not poisonous. It loses the bitter taste, to some extent, but not entirely, after several months keeping.

E. P. MASSEY.

Waco, Texas, July 13, 1883.

Bees in Alabama.

We have had a perfect drouth almost ever since April 1. Until the last 10 days, bees have scarcely gathered enough honey to keep up brood-rearing. But now the sourwood is just in, and it brought honey with it; bees are booming, and the honey is very white. Some ask when we can rear the best queens? We can rear just as good queens in one month as another, from April to September, provided our rules are carried out, viz.: plenty of pollen, plenty of honey, and plenty of bees. This has been one of the coldest and most backward seasons we ever experienced. We had frost in May. If there are any bee-keepers who wish to move South, there is room enough among our mountains; thousands of pounds of honey are wasting for the want of bees to bring it in.

T. S. HALL.

Kirby's Creek, Ala., July 2, 1883.

Basswood Opening.

Bees have done very well up to the present week; this week has been too cool and wet. Basswood is just opening.

J. I. PARENT.

Charlton, N. Y., July 14, 1883.

Comb Foundation.

MR. EDITOR:—I send you by this mail samples of foundation made on the Given press, in answer to Messrs. Bray & Seacord, of Warthan, Cal., on page 338 of the BEE JOURNAL. For thin foundation the only difference is the sheets are thinner; the work is the same after being sheeted. There is no change in machinery from heavy foundation to thin foundation. It works thick and thin simultaneously. Bees here are just waiting for something to turn up; just making a living. Thus far, the honey harvest in northern Texas might be represented numerically as follows: 000 pounds; if we have no change, two more naughts may be added, making it 00,000 pounds, surplus honey for 1883. We hope our Kentucky friends will remember us kindly at their coming convention. I am happy to greet America's greatest bee-master, Rev. L. L. Langstroth, again. He is our father in bee-literature.

WM. R. HOWARD.

Kingston, Texas, July 10, 1883.

[The samples are received; both the thick and thin foundation have very thin bases to the cells, and as both were made on the same mill, this full answers the query of Messrs. Bray & Seacord.—Ed.]

Honey from Blue Thistles.

Our prospects for a good crop of honey were never better. The spring was late, but since settled weather came, the bees have built up rapidly. Swarming is in full blast. On Friday of last week, one of our box-hive-beemen had 8 swarms in one bunch. He hived the first swarm that came off on that day; seven others came out and clustered on the hive in which the first had been hived, thus making 8 swarms together. They were divided and put in 3 or 4 boxes. Have not heard how they were doing. My bees are storing honey rapidly from blue thistle. This honey is very white and of fine flavor.

J. W. CARTER.

Pleasant Dale, W. Va., July 11, 1883.

Dog Fennel Honey.

Last year I had some very late swarms that gathered a great deal of honey from dog fennel. The honey is unfit for use, having a bitter taste; one dose was enough for me. Two colonies had nothing but dog fennel honey to winter on, and came through as strong as any. Bees will not gather honey from dog fennel when there is anything else to work upon, though it blooms from June until October. There is an immense quantity of it in this country, making the fields look perfectly yellow.

W. S. DOUGLASS.

Lexington, Texas, July 16, 1883.

Died.—My little son, Wm. R. Howard, died of congestion, after a short and painful illness, on the 3d inst. Aged 3 years, 8 months and 26 days.

WM. R. HOWARD.

Kingston, Texas, July 12, 1883.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5. or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Articles for publication must be written on a separate piece of paper from items of business.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

Do not send coins in a letter. It is dangerous and increases the postage unnecessarily. Always send postage stamps, for fractions of a dollar, and, if you can get them—*one-cent* stamps; if not, any denomination of postage stamps will do.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 50 cents; per hundred, \$3.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
" 100 colonies (220 pages)..... 1 50
" 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Do not let your numbers of the BEE JOURNAL for 1883 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Detecting Glucose Adulterations.

We have received from the Rev. L. L. Langstroth, the following letter concerning the recent discovery of the new phase of the glucose abomination:

OXFORD, O., July 20, 1883.

FRIEND NEWMAN:—I enclose you what I hope will prove a good way of detecting glucose adulterations. I have the promise of some glucosed maple sugar bought in the open market, which will be soon tested. We propose to move all along upon the enemies' lines. I am aware that these exposures must, for a time, to a certain extent, injure the honey trade; but they are necessary, and in the end will help it. If bee-keepers kept silence, where would these frauds stop? The good old AMERICAN BEE JOURNAL has done much honest work in this matter. How long will it take to excite a State or the whole country if a President, or even a Senator or Governor is to be elected, so that vast sums can be raised for election expenses, and yet the people rest almost passive upon the immense frauds of adulterators, who are often destroying health and even life! It is hard to move us in this matter, but the steam of a righteous indignation is making, and its power will be felt.

Please correct the only important error of the press in my last communication. I said, "for we do not believe that this company is a sinner above all others," etc., and the types made me say, "we do believe," etc. Mr. McCord and myself do not wish to make personal attacks upon any one, or to single out any one concern. If any of the many glucose manufacturers feel aggrieved by our exposure, it cannot be helped. Again, I challenge them, or any of their advocates, to name for what legitimate purposes the immense quantities of glucose products are used. I ask them if they dare to say to what uses they are actually put. We wish "the

truth, the whole truth, and nothing but the truth."

L. L. LANGSTROTH.

The letter referred to by Mr. Langstroth, with the method of testing honey, syrups, etc., by Prof. B. F. Marsh, of the Miami University Training School, is as follows:

OXFORD, O., July 18, 1883.

DEAR SIR:—In answer to your request that I should indicate some easy method by means of which impurities in glucose, syrups, etc., could be detected, I submit the following.

The impurities most common in manufactured glucose are calcic sulphate, known as sulphate of lime, and sulphuric acid. Calcic sulphate is insoluble in alcohol. If, therefore, a drop of glucose containing any of the above salt be thoroughly mixed by shaking in a glass vessel with four or five tablespoonsfuls of strong alcohol, a white precipitate of calcic sulphate will appear and make the solution milky. The above test is generally all that is necessary to detect the presence of the sulphate of lime. It may be necessary, sometimes, to add a drop or two of sulphuric acid to the solution before the precipitate will appear.

For the detection of sulphuric acid, a drop or two of the suspected glucose is to be placed in a glass vessel and dissolved in two or three tablespoonfuls of water. Add a few drops of chloride of barium to the solution, when, if sulphuric acid is present in considerable quantity, a white precipitate will appear and make the solution milky. This test will generally be all that is necessary to indicate the presence of sulphuric acid in glucose. When the acid is present only in minute quantities, it will be necessary to add to the solution of glucose and water, a drop or two of dilute chlorhydric or muriatic acid before adding the chloride of barium. In making the tests, rain water should be used. It is hardly necessary for me to add that pure honey contains no lime or sulphuric acid. There is, however, in all pure honey, a slight trace of formic acid which is secreted by the bee; but this acid will not interfere with the tests which are indicated above.

With great respect, I am,

Yours Truly, B. F. MARSH.

Rev. L. L. LANGSTROTH, Oxford, O.

It will be remembered that the glucose manufacturers wrote to Mr.

McCord that "they feed it [glucose] very largely in California, and make money out of it." Mr. Wm. Muth-Rasmussen has sent us the following very emphatic denial of the accusation:

MR. EDITOR:—I have just read Mr. Langstroth's article with your comments on page 341, AMERICAN BEE JOURNAL.

Allow me to say, that during my 14 years' experience in the bee business in California, I have never seen glucose, nor have I among my large number of bee-keeping acquaintances found any who ever had. I know of bee-keepers, who in seasons of drouth bought honey in San Francisco to feed to their bees to save them from starvation. They paid 7 cents and freight for honey which they had sold the previous year for 5 cents. Others bought grapes at the vineyards and hauled load after load to the mountain apiaries to save the bees. I never heard of grape sugar being used for that purpose, though it is not impossible. But the assertion, that "they feed it (glucose) very largely in California, and make money out of it," I shall not hesitate to pronounce in the meaning it is intended to convey, as an *unmitigated lie*.

I doubt that glucose or grape sugar either can be found in this State outside of San Francisco. I believe it is used there by packing firms, as it is but a short time since I saw in one of the stores here a small can of honey which had been there for 6 years, and was still liquid. The "honey" was rather dark, of inferior flavor, and thinner than good honey ought to be, still it was labeled "Orange Blossom Honey," "Warranted Pure." Two bare-faced lies on each can. Every one familiar with southern California knows that bees never get orange-blossom honey to amount to anything. The orchards are too far from the apiaries, and the orange tree blooms in the winter and early spring, when bees never fly far in search of food.

The price of honey in California is governed by the price in the eastern States, deducting freight, commission and other incidental expenses. Any one can, therefore, by looking at the quotations in the bee papers see that a man is not liable to grow rich by the bee business here. You cannot, Mr. Editor, more than I regret that another drawback should be added to the often precarious living of the

California bee-keeper, by the false assertions of this "Grape Sugar Co."

I enclose a clipping from the *Pacific Rural Press*, March 24, 1883, by which you will see that a new sweetening compound has been invented, and is going to be used to adulterate glucose with. Can you, or any of our scientific bee-keepers, tell us anything further about this "benzoic sulphide?"

WM. MUTH-RASMUSSEN.

Independence, Cal., July 19, 1883.

The following is the new compound for adulterating glucose, mentioned by Mr. Muth-Rasmussen:

A NEW SWEET COMPOUND.—C. Fahlberg, in a paper read before the Franklin Institute, Jan. 17, furnishes some interesting particulars in relation to his discovery of a certain sweet compound in the hydrocarbon of the coal tar group. He describes the sweetness as being very intense. As soon as he made the discovery, he proceeded at once to determine whether it was poisonous to take it in larger quantities or not. At first a cat and then a dog were subjected to experiment, but they remaining alive and apparently not in the slightest degree affected by it, the discoverer decided to take several grammes of it himself. The result was not the slightest inconvenience experienced from it. A chemical test of the urine, made the next morning, showed that almost the entire quantity taken could be thus recovered.

The compound obtained, and which contained the sweet principle, forms salts with any carbonate of the alkalis, alkaline, earths or metals and all of which taste sweet. It is, however, not an acid, but belongs to a class of bodies to which the name "Sulphines" has been given; the compound in question being benzoic sulphide. It is very readily soluble in alcohol, more so than in cold water, in which it only dissolves readily when it is hot. The discoverer says: "I am making the attempt now to prepare it in larger quantities, and by cheaper methods, and have no doubt that it will find extensive use in medicine and for technical purposes. One experiment made was to sweeten glucose, which, as you all know, tastes only faintly sweet, and the result was a complete success. As soon as I shall have found the method by which to prepare it on a manufacturing scale, I shall come before you again, and as I trust and hope, with larger samples than now, ready to give answer to all questions in regard to its price, application, etc."

This "benzoic sulphide" is new to us, and, if its career is to be anything like its twin-fraud—glucose—it were better if it should be consigned to eternal oblivion.

Do not let your numbers of the BEE JOURNAL for 1883 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

Bee and Honey Show at Toledo, O.

The Tri-State Fair (Ohio, Michigan and Indiana) will be held at Toledo, O., Sept. 10 to 15, 1883. The following is the list of premiums in the Apiary Department, of which Dr. A. B. Mason, of Wagon Works, O., is the superintendent:

	1st. Prem.	2d. Prem.
Display comb honey in most marketable shape, product of one apiary in 1883.....	\$10	\$5
Display extracted honey in most marketable shape, product of one apiary in 1883.....	10	5
Display extracted honey in most marketable shape, by a lady, product of her own apiary in 1883.....	5	3
Display comb honey in most marketable shape, by a lady, product of her own apiary in 1883.....	5	3
Comb honey in most marketable shape, not less than 20 lbs., quality to govern.....	4	2
Extracted honey in most marketable shape, not less than 20 lbs., quality to govern.....	4	2
Crate or case comb honey, not less than 20 lbs., in best shape for shipping and retailing.....	4	2
Colony bees.....	5	3
" Italian bees.....	5	3
" Syrian bees.....	5	3
Colonies of bees must be the progeny of one queen, and exhibited in such shape as to be readily seen on two sides. Purity of race, docility, size of bees, and numerical strength to be considered.		
Display of queens, put up in such shape as to be readily seen by visitors; blacks not to compete.....	3	2
Greatest variety of queens put up as in display of queens.....	3	2
Queens and colonies cannot compete for more than one premium.		
Bee hive for all purposes in the apiary, may be represented by a model not less than half size.....	3	2
Bee hive, glass.....	2	1
Wax extractor.....	2	1
Honey extractor.....	2	1
Foundation mill.....	5	3
Foundation press.....	5	3
Beeswax, not less than 10 lbs.....	2	1
Comb foundation for brood-chamber, not less than 5 lbs.....	2	1
Comb foundation for surplus honey, not less than 3 lbs.....	2	1
Comb foundation machine making the best foundation for brood-chamber on the grounds.....	8	4
One piece sections, not less than 50.....	1	50c
Dovetailed sections, not less than 50.....	1	50c
Packages with labels for retailing extracted honey....	1	50c
Bee smoker.....	1	50c

Honey knife.....	1	50c
Package for shipping extracted honey in bulk....	1	50c
Machine for making holes in frames for wiring.....	2	1
Machine for wiring frames.....	2	1
Display apiarian supplies....	3	1
Quinces preserved with honey.....	2	1
Peaches preserved with honey.....	2	1
Apples preserved with honey.....	2	1
Pears preserved with honey.....	2	1
Largest and best collection of bee literature.....	2	1
Largest and best display of honey bearing plants, properly named and labeled....	10	5
Queen cage, such as is admitted to the mails by the postal laws.....	1	0
Honey vinegar, not less than one gallon.....	2	1
Honey cake, with recipe for making.....	4	2

Bee and Honey Show.—The twenty-third St. Louis Fair opens Monday, Oct. 1, and closes Saturday, Oct. 6, 1883, and offers premiums, \$50,000. The following are the premiums for Bees and Honey:

Best display of Italian bees	\$20
" display of black native bees.....	20
Best imported queen.....	10
" display of comb honey 25 lbs.....	Dip. and 10
Best crate of honey in comb	L.S. Med.
" bee hive for all purposes	Dip.
" honey extractor.....	Dip.
" wax extractor.....	Dip.
" bee smoker.....	Dip.
" honey knife.....	Dip.
" bee veil or face protector.....	Dip.
Best display of apiarian implements.....	1st Dip. & \$25 2d L. S. Med.

The secretary writes us as follows: "We make no charge for entry or space, and will allow the sale of products, provided a neat display is made, and stock is replenished, during the entire week. We contemplate allotting a building exclusively to this department."

Mr. J. F. Tearman, of Lincoln, Ill., has sent us a copy of the Premium List of the Fair to be held at Lincoln, Ill., on Aug. 27 to 31. The following are premiums for "bees and honey"—just three; no more and no less—the whole amount of premiums being but just \$18. Let us hope that heretofore they have offered none, and that this is their first effort:

	1st.	2d.
Bee hive containing colony of bees.....	\$5 00	\$2 50
Display of apiarian supplies.....	5 00	2 50
Five pounds of honey in comb.....	2 00	1 00

Bee and Honey Exhibition.

There will be held, at the Southern Exposition, August 28 to September 1, under the direction of the Agricultural Committee, an exhibition of bees and honey, when the following premiums will be awarded:

1. For best exhibit of Italian bees in observatory hive	\$25 00
First.....	25 00
Second.....	15 00
2. For best 50 to 100 pounds of comb honey produced in Kentucky in best shape for retail trade or for family use	20 00
First.....	20 00
Second.....	10 00
3. For 50 to 100 pounds of extracted honey produced in Kentucky in best shape for retail trade or for family use	20 00
First.....	20 00
Second.....	10 00

NOTE.—The premiums No. 2 and No. 3 above are offered by the State of Kentucky through Hon. Chas. E. Bowman, Commissioner of Agriculture, and are confined to the products of Kentucky.

RULES OF THE EXHIBITION.

1. The exhibition will be in charge of the Superintendent of the Agricultural department.
2. Bees in observatory hives must be so confined that they shall not have exit in the Exposition building.
3. Table room for the exhibits will be provided by the Superintendent.
4. Articles for exhibition sent by express must be directed to the Southern Exposition, marked "Bee Exhibition," and charges must be prepaid.
5. Exhibitors will be admitted free on August 28 and 29.
6. All exhibits must be entered and placed upon the tables by 1 o'clock p. m., August 28, at which time judges will award the premiums.
7. Judges will be appointed by the Agricultural Committee.
8. The premiums will be paid in cash.

The National Convention.

The National Bee-Keepers' Association, will hold its Annual Convention in the City Hall and Council Chamber in the city of Toronto, on Tuesday, Wednesday and Thursday, the 18th, 19th and 20th days of September, during the second week of Canada's Great Fair. All the railroads in Canada will issue tickets during this week, good to return, up to Saturday night 23d, at single fare for the round trip. Special excursion rates will be arranged from various parts of the United States, of which due notice will be given. Those who intend being present may be kept posted on the latest excursion rates, etc., by addressing me, and also that I may arrange hotel accommodation. Private lodgings will, if possible, be secured for those who desire it, and every effort will be made to make everybody comfortable. A grand meeting is anticipated.

D. A. JONES, President.

Articles for publication must be written on a separate piece of paper from items of business.

The Honey Flow.

Mrs. L. Harrison, in the *Prairie Farmer*, makes this statement of the case:

The flow of nectar from white clover still continues, and judging from recent rains, it appears as though there would be no interim between its bloom and fall flowers. Some bee-keepers of this State report "honey dripping from their garments," and this is literally true of those who extract. The flow of honey, this season, has not been continuous, but off and on, resulting in the rearing of multitudes of bees. When swarming has been controlled to the extent of keeping all hives full to overflowing with bees, satisfactory results in honey will be obtained.

Dio Lewis' Monthly is the title of a new serial, the first number of which is on our desk. It is a handsome magazine printed in clear type, and is devoted to health and hygiene. It is published by Clark Bros., 68 Bible House, New York, at \$2.50 a year. The editor remarks as follows:

It is conceded that the cloud overhanging this wonderful land is the doubtful health of its people. With good digestion and good nerves we can more than realize the world's brightest hopes. The aim of this magazine is to popularize sanitary science. We shall strive to make the subject of the health of our bodies as simple and interesting as a story.

The pamphlet, "Honey, as Food and Medicine," is in such demand, that we find it necessary to print them in still larger quantities, and can, therefore, still further reduce the price, as noted on page 387. Let them be scattered like "autumn leaves," and the result, we feel sure, will fully reward honey-producers for both the labor and the small expense.

St. Joseph, Mo., Honey Show.—We notice by the *St. Joseph Gazette* that Mr. D. G. Parker is again appointed superintendent of the apianian department of the St. Joseph Exposition. We hope it will be a grand success.

Last spring Mr. D. C. Talbot described his "Comb Foundation Fastener" in the *BEE JOURNAL*, and afterwards advertised it for sale. Now we have two complaints from parties that have sent for, but, so far, have not received it. We have written him twice about the matter, and getting no reply, we fear there is something wrong, and now publicly ask for an explanation.

Postage on Queens to Canada.—On any package of merchandise sent to Canada, of 8 ounces or less, the postage is 10 cents. Queens, therefore, cannot be sent for less than 10 cents each. Canadians ordering queens from the United States, should add 10 cents for each queen, if they are to be sent by mail, for that extra 10 cents will usually eat up all the profits on queen bees, if they are reared as they should be.

The new two cent rate of postage for letters goes into effect on October 1. Three cent postage stamps will then be but little used. For all fractions of a dollar sent to us hereafter we should prefer either *one-cent*, or else five or ten-cent postage stamps. Do not send coins in any letter.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL. }
Monday, 10 a. m., July 30, 1893. }

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—Extracted honey commences to come in freely, and a large crop is reported from all quarters. The demand is very good, and keeps pace with the arrivals. For choice extracted honey 1 pay 7 $\frac{1}{2}$ ¢; the latter price for choice clover. I have received several nice lots of comb honey, for which we paid 15 $\frac{1}{2}$ ¢ to 16¢ on arrival.
BEESWAX—Arrivals of beeswax are plentiful. We pay 32¢ for a good article on arrival.

CHAS. F. MUTH.

NEW YORK.

HONEY—Best clover in 1-lb. sections (no glass) 26 $\frac{1}{2}$ ¢; 10 2-lb. sections (glass) 18 $\frac{1}{2}$ ¢. Fair quality, 10 2-lb. sections, 16 $\frac{1}{2}$ ¢ to 17¢. Extracted, white, in small barrels, 10 $\frac{1}{2}$ ¢ to 11¢; buckwheat, 8 $\frac{1}{2}$ ¢ to 9¢.
BEESWAX—Is more plentiful. Prime yellow sells at 36 $\frac{1}{2}$ ¢.

H. K. & F. B. THURBER & CO.

CHICAGO.

HONEY—New crop of comb honey is being offered, and some sales of it have been made at 16 $\frac{1}{2}$ ¢ to 18¢ in 1 and 1 $\frac{1}{2}$ frames. The receipts of extracted are liberal, and there is a good deal of complaint about orange honey; consumers holding off. Market, 16 $\frac{1}{2}$ ¢ for white. Very little dark left, and some inquiry for it.

BEESWAX—30 $\frac{1}{2}$ ¢ to 35¢.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—New extracted is arriving freely—selling for 7 and 8 cts. New comb coming forward slowly; extra white, 10¢.
BEESWAX—No beeswax in the market.
STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Considerable new arriving, and selling in lots at 7 $\frac{1}{2}$ ¢ to 7 $\frac{3}{4}$ ¢ for extracted in cans; 14 $\frac{1}{2}$ ¢ to 15¢ for comb. Old and all poorer offerings neglected and nominal.
BEESWAX—Easy, but sold mainly at 29 $\frac{1}{2}$ ¢ to 30¢.
W. T. ANDERSON & CO., 104 N. 3d Street.

CLEVELAND.

HONEY—There is a very good demand for new white honey at 18 $\frac{1}{2}$ ¢ to 20¢ for 1 lb. sections; 2 lb. new 17 $\frac{1}{2}$ ¢ to 18¢; old, 15 $\frac{1}{2}$ ¢ to 16¢. No extracted has been received, and none seems wanted in our market.
BEESWAX—32 $\frac{1}{2}$ ¢ to 35¢.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—Our market is fairly active. We quote: $\frac{1}{2}$ lb. sections at 30¢; 1 lb. sections, 22 $\frac{1}{2}$ ¢ to 24¢; 2 lb. sections, 20 $\frac{1}{2}$ ¢ to 22¢. Extracted, 10¢ per lb. Good lots of extracted are wanted in kegs or barrels.
BEESWAX—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatham Street.

CORRESPONDENCE

For the American Bee Journal.

That "Long Idea" Hive.

G. M. DOOLITTLE.

On page 223, A. W. R. asks why I do not adopt and practice the method used in getting the 596 pounds of extracted honey spoken of on page 115. Ten or more years ago D. L. Adair, of Kentucky, was quite a prominent bee-keeper and writer for the bee papers. He used and advocated a long hive to be used on the principle of spreading the frames out horizontally instead of tying one hive above the other, claiming that, thereby, a colony of bees could be kept in a normal condition, and while in said condition no swarming would be the result. This hive he termed the "long idea" hive. Being always ready to test all the "new ideas," I made two hives four feet long, during the winter of 1873, but did not put them in use until the summer of 1877. One of these I worked for extracted honey, as given on page 115, and the other for comb honey, on Mr. Adair's plan.

The one worked for comb honey swarmed, and after repeated trials to keep them at work in the 4-foot hive, I let them have their own way when they had swarmed for the fifth time, and lived them in an empty hive.

The one worked for extracted honey did splendidly, but another worked on the "tying up" plan did nearly as well, and by practical knowledge I learned that I could work a two or three story hive much more easily than I could this long one. To take the frames out, the person's back must be bent just enough to make it the hardest kind of work, and the bees which were shaken off the combs would crawl all over the sides and top of the hive in such numbers as to make it almost impossible to close it again. With the two story hive the bees could be shaken on top of the frames in the lower hive, when they would crowd below until the hive was closed, and the operator could stand erect while at work at the hive. But the worst thing about it was that I lost both colonies during the next winter, after fixing them in good shape for winter, as I considered. I have tried the hives since with no better success, so have torn them to pieces and made others of them.

A. W. R. further wants to know "what became of the 70,000 workers in winter." As the honey season drew to a close, or about the first of August, the queen ceased to lay in all but about six of the central frames, so that by the first of November the hive contained no more bees than others having only nine frames during the season. The worker bee lives but about 45 days during the summer months, hence it comes to pass, as soon as the queen ceases her extra prolificness, that the workers

rapidly diminish, till but an ordinary colony exists for winter. He that over-rides all things made the honey bees so that as summer approaches their instinct leads them to usher a host of bees into existence to gather the honey about to be secreted, and as this passes by, the same instinct leads them to prepare for winter, by decreasing their numbers. In this, as well as in many other things, we see how perfect was the work of the Creator.

Borodino, N. Y.

Michigan Farmer.

Selecting Location Before Swarming.

PROF. A. J. COOK.

I send you this interesting letter of Mr. F. E. Delano's, one of our graduates, and a farmer at Oxford, Mich. A case almost identical is reported from England. This seems to prove that scouts are sent out before swarming to pre-empt the future home, and that clustering just after the swarm issues, is not to give time to look up a home, but more probably to give the queen, which has not tried her wings for months—probably years—a brief rest after the short flight, from hive to cluster, before the longer one is commenced.

OXFORD, June 24, 1883.

To Prof. A. J. Cook.

As you are now interested in imparting what is known about the "little busy bee" to those who are still nervous about shaking hands with them, and still more so about having them tenants of the same house. I will tell you of an interesting occurrence that has taken place here, and in which a swarm of bees are especially interested. We are engaged in rebuilding a part of our house; the upright has not been torn down, and on the side where we are putting up the new part the joists run through the wall. There happened to be some holes next to the ends of two or three. Friday afternoon it was very warm; for a long time I had noticed that there were bees around the house, and had made some casual remarks concerning them, but paid no attention otherwise to their continual hum. Finally we looked around, and found that to all appearances a swarm of bees had gone into the house under the chamber floor. As a swarm of bees make considerable noise when they fly, and as we had heard no unusual or increased amount of humming, we concluded that they must have come when we were at dinner. Again, we could hardly credit that conclusion, for it was half-past three before we had heard a bee at all. That night all we could do was to make conjectures concerning their arrival. The mystery was satisfactorily explained about 9 o'clock Saturday morning. About half-past eight we noticed that there was not a bee around, so did not know but that they had left. Well, they had, but not for good, for about nine the swarm really came, and this time they made noise enough. It was a

big swarm, too. Now, for the conclusion: The bees that came Friday were either a scouting party sent in advance, or else they came to clean out and make ready, which, I do not know; but think probably the place had been selected before, and that this regiment had been sent on to make ready for the swarm, for they were very busy until night. Then Saturday morning the regiment went back and piloted the swarm to the new found home.

Whether the swarm came direct here from the hive or not, I do not know. There are bees kept three-quarters of a mile south of here. I shall go and see if a swarm left there Saturday morning.

This is positive proof in this case, and I suppose it is so in all, or most at least, that the place is selected before the swarm go to it. I have been minute in my description because the circumstance was interesting, and I never remember of reading or hearing anything positive in regard to the matter before.

FRED E. DELANO.

For the American Bee Journal.

The Traffic in Queens.

JAMES HEDDON.

Some 20 years ago a new race of bees was introduced to American apiarists. This race was called Italian. They were plainly and distinctly marked physically, and possessed also distinct traits of character. Some of their characteristics were, when compared with our old-time tried Germans, found to be superior, and some inferior. The common voice of the majority of apiarists pronounced them best, all points considered. Then came a demand for these bees. It was found that they readily lived and mingled with our Germans, and that to put an Italian queen in the place of a German queen, would change the whole colony in a few weeks. Then there came a demand for queens.

The rearing of queens to fill that demand was the next effect. The breeder began to select colonies of pure Italians to breed from, and as he had more than one pure colony, he began to look about for some way to decide which colony he should use. There is not on record a case where a cent was thrown up, "heads or tails," to settle on the colony to select eggs or cells from. Quicker than a flash the master's good sense said, "this one gathers the most honey, and behaves the best, and, of course, I shall use it." Then and there a new system of breeding was born. "Spontaneous generation." Breeding for qualities began, never to cease as long as man and bees remain in partnership in the production of honey. Years rolled on, and no one thought of improving any race of bees except the Italian.

Quite often controversies came up as to which race was, "taken all in all," the best. Then the good and bad qualities of both were ably shown

up. When looking at this picture, thoughtful bee keepers carefully weighed the good and bad points, and struck a balance; some said "the Germans are the best," more said "the Italians are best." Acquisitive honey-producers said, "Why can't we combine the good qualities of both races?" Determined breeders said, "We can and we will," and now, queens bred for qualities, and not for the purity of any race, are pouring through the mails like streams through a desert.

At last, in spite of all mistaken and interested opposition, the time has come when the leading honey-producers of this country can use and sell the same stock—the bees of their choice. I have private means of accurately estimating the popular public sentiment of to-day regarding this subject; also its growth during the last few years. I predict a glorious future for the development of "*Apis-Americana*." At last, in the traffic of queens, the breeder finds honesty and interest together.

Before I close I wish to say a few words regarding what kind of queens are best for purchasers to buy. If one is so well satisfied that he has his eye on the strain of bees he is going to possess, I know of no way better than to buy untested queens and put one at the head of each colony. I did this with 40 colonies in 1871, and paid \$2 each; but if, on the other hand, the purchaser wishes to test the strain before changing to it, or for any reason sees fit to rear his own queens, he should by all means order one, or as many more as he can afford, of tested queens. They will prove much the cheapest in the end, as every breeder very well knows. The idea of purchasing one untested queen to test a strain by, is preposterous in itself. I am of the opinion that the more tested and less untested queens are purchased, the faster we shall march toward that coming bee. No man should ever breed from an untested colony.

Dowagiac, Mich., July 16, 1883.

Combs Built in Wired Frames.

T. A. HOUGAS.

In regard to the impracticability of wiring frames except for foundation, is fully settled in my mind. I should not do so, as I consider it but a waste of time and money. This spring I experimented on this in two ways.

1. I placed wired frames, and frames with full sheets of foundation alternately.

2. With nothing but wired frames in the hive.

In the former they built the combs from top to bottom of the frames in strips, not averaging over $1\frac{1}{2}$ inches wide. The wire was precisely in the centre of the comb in each and every case. They did not seem to want to unite these combs (there was two or three of these combs in each frame), so as to make the frame solid, but would leave large openings in them.

In the latter they seemed to be bewildered. Some combs they built properly, while with others the wires seemed to be in the way. In one case they built exactly at right angles with the frames. In one case a line of drone cells was built on either side the wire the full length of the comb.

In another instance I wired a frame and filled it with foundation just half way down from the top-bar. They drew out the half sheet and a full sheet on the outside of a division-board before they completed the half-filled frame.

After thus experimenting, I have concluded that it would be utterly useless, if not more than useless to wire a frame unless you fill it with foundation. I agree with Mr. Henderson, that it is impractical.

Henderson, Iowa, July 16, 1883.

For the American Bee Journal.

Experiences of a Novice.

BY A NOVICE.

This article is headed thus, so that old bee-keepers may skip over it. It is written by a novice for novices.

I bought a colony of bees late in the spring; a strong colony. The hive was called a Langstroth, or I should not have bought the bees. Not liking the old unpainted hive, I sold it to the man who sold me the bees. After a fortnight, according to agreement, I attempted to transfer the bees to a new Langstroth hive, when I found the bar of the frames half an inch too long to set in my hive. I, however, succeeded by putting one end of the bar in its proper place, and allowing the other end to rest on the top of the brood-chamber.

The combs were very thick and irregular, and were half full of honey. After a while the hive became too full of bees, and not being able to secure an experienced hand to divide them, I placed a new hive about 8 feet from the full colony, and then exchanged their places. Took two thick-combed frames of bees from the full colony and put them into the new with a frame of foundation on each side, and a division-board. I could not find the old queen, so I chose a frame with a queen-cell, and left in the other hive a queen-cell.

In a few weeks the old colony seemed again to be in need of being divided. I had replaced foundation frames where I had taken the frames of bees. These had cells, and were covered with bees. This time I secured the services of an experienced bee-keeper. He took the full hive about $2\frac{1}{2}$ rods away, and put the new hive where the old one had stood, and put with it two frames of bees, and a frame of foundation on each side; but he could find no queen. The next day not more than 200 bees remained in the new hive, the rest returned, I think, to the old one, so now I propose to put the two new colonies together. When the last division was made, I found the honey all gone, and commenced feeding them, near the entrance, with syrup from granulated

sugar, but the flies took half of it.

On inquiry I found a better way was to soak a slice of corn bread in the syrup and put it on the frames under the cloth and cap. Yesterday, I tried the plan, and with such benevolent intentions I thought I need not take the veil nor smoker, but I carelessly irritated the bees, and three of them felt called upon to teach me to be more gentle. I had, before this time, put into my vest pocket a vial of carbonic ammonia, and was now anxious to try its virtues. I did so, but this morning I have a very large fat hand. I am now ready to try another prescription. The veil and smoker soon set things all right.

By the way, I had prepared 40 sheets of paper with nitre, and rolled up with one sheet some cotton rags and wood, put it into the smoker and lit it with a match, but being in a hurry my match fell down upon the rest of the paper, which I threw upon the ground to stamp out the fire, but did not succeed. I have since prepared more, and thank Mr. Higbee for his information in the Weekly BEE JOURNAL. These experiments have taught me several things:

1. Always treat the honey bee gently and respectfully.
2. Always use a smoker and veil when handling bees.
3. Prepare the smoker as recommended by D. Higbee.
4. Never depend on powdered carbonic ammonia.

Bees in Washington Territory.

C. THEILMANN.

I have just come home a trip from Medical Lake, Washington Territory, the great bathing resort of Spokane county, where hundreds of people have restored their health by the waters of Medical Lake, of which I am one that was cured of many years' biliousness.

Traveling considerably in the Territory, I have only found bees in the vicinity of Walla Walla. They seem to do splendidly, and are gathering a good deal of honey there, but the bee-keepers do not manage them very well. I only saw one (an Iowa man) that had some kind of movable frames in his hives, though very poorly gotten up. All the rest that I saw, had their bees in box hives, and did not know how to get any honey, unless they brimstoned the bees in the fall.

Walla Walla valley seems to be well adapted for bee-keeping, as they hardly ever lose any colonies in winter, for the winters are generally very mild.

I purchased 2 colonies, the only two the man had which would not offer to sting in handling, and transferred them 150 miles North, to the lake above mentioned, and are the first bees that have ever been taken North of Snake river; they are gray-looking bees, different from the rest I saw around Walla Walla, but I saw such bees last year while traveling through Arizona. How those gray bees reached

Walla Walla I cannot ascertain; all I know is that they do not offer to sting, for all that, they have stings as well as other bees. I would like to get some information about the gray Arizona bees, through the BEE JOURNAL, about their habits, etc.

My bees here are doing well. White clover has been better than ever heretofore, and basswood has just commenced to bloom a day or so ago, and promises a large yield.

I have just received a letter from my son, written 10 days after I left Medical Lake, saying that these gentle bees are doing nicely. He is living at the Lake and is attending to them.

Theilmanton, Minn., July 19, 1883.

[Will some one in the Territories please reply to the above? Are they not the same grey bees that are found in the South?—Ed.]

For the American Bee Journal.

Bee Notes from Mississippi.

O. F. BLEDSOE.

My bees are doing well this season, and are profitable in pecuniary returns, though I cannot yet obtain results to compare with those of some Northern bee-keepers. I am, however, encouraged in the business. I am satisfied that in this locality, and almost anywhere in the South, there is each year ample honey flow to make bee-culture profitable. The great problem with me is the best method for controlling the swarming fever.

It is difficult here to keep bees at the point, in strength, at which they will make comb and seal comb honey, and yet not swarm. My plan is to shade, ventilate, remove all drone comb, to provide ample room to cluster and build comb at the sides, confining the brood nest by division boards, and to remove all sections from the top as soon as sealed over. I clip one wing of every queen. If a swarm issues and I do not desire to put it in a new hive, I let it return and remove the queen, or return her to the hive caged. On the seventh day after swarming, I open the hive and cut out all queen cells. Nearly all the brood will by this time be sealed over, but lest the bees will take some of the youngest unsealed larvae and try to make a queen, I select five of the youngest queen cells and put them back directly over the brood nest in the place of a section box, which has been taken out for the purpose. After two days more, I remove all these queen cells and let out the queen, or, if the queen has been taken from them, remove all the cells but one. Under these circumstances, the bees are compelled to stay and go to work, and, if ample room is given, will not often swarm again, especially if they have a young queen from a cell left to them. As fast as new comb is made in the frames at the sides, it is cut out while still white and pure, the honey extracted, and the comb used in section boxes.

I can get much more, and more beautiful comb in this way, than if I

put section boxes at the sides in the brood frames. The bees are quicker to go to work in common frames with good starters or foundation; more bees can get to work, and, the building-clusters being more continuous, they make more rapid progress.

The frame I have adopted is a shortened Langstroth frame, that fits exactly in the Langstroth hive when turned round, and the entrance put in one of the sides; dimensions of the frame, $13\frac{3}{8} \times 9\frac{1}{8}$. A broad frame of these dimensions will hold exactly six $4\frac{1}{4} \times 4\frac{1}{4}$ sections. Nine of these frames in brood nest take $999\frac{1}{2}$ square inches of comb, the Doolittle standard for brood nest being 1,000 square inches of comb. If those who use Langstroth hives should use these short frames for awhile, they would not insist on a frame $17\frac{3}{8} \times 9\frac{1}{8}$ as the best for a standard. The Langstroth frame is certainly of the proper depth to obtain the best results in comb honey, but for many reasons it is too long; and, among others that it does not admit of the proper arrangements for the side-building of comb, and this is certainly the correct principle in the production of comb honey.

Grenada, Miss., July 24, 1883.

For the American Bee Journal.

The Honey Crop Not a Large One.

J. L. GRAY.

Please allow me to protest against the almost universal practice of writers in bee papers (especially those who have kept bees only for a short time) of exaggerating the bee business in general, and the present crop of honey in particular. This gives honey dealers the impression that the markets are about to be flooded with the largest crop of honey ever known. The bee papers are full of glowing accounts of the wonderful yields in certain parts of the country, while those that are getting light yields, or none at all, do not report; the dealers only seeing one side of the report, take it for granted that they can safely cut the prices, and are not slow to do so.

The crop of honey in this part of the country is away below an average, so far this season; some of the most successful apiarists not having secured any surplus as yet, and clover and basswood are nearly over.

Mr. James Heddon has, for years, manfully fought against this and kindred wrongs; he has stood unaided, and almost alone, against the practice of many who coax, yes, almost pull everybody into a business already crowded; he has been called selfish, because after he had been to a great expense, and had devoted the best years of his life to make a success of what these same outsiders had laughed at. He protested against trying to persuade everybody—invalids, cripples, and lazy good-for-nothings to step in and overstock a pasture he has by all means the best right to.

I know how this works, for I have had a practical illustration with one

of the kind who thinks that the more swarms he gets the more successful he is. It is not selfish for a person to look first to his own interests, and secondly to mankind in general.

What would we think of a doctor, lawyer or merchant who would continually try to convince others that his was the best paying business, and want everybody to open a store or office and take part of his trade or practice from him. I would think him "short of wit," but I suppose others might say he was selfish, if he did not do this.

Lee Centre, Ill., July 25, 1883.

[We give place to the above *at once*, so that the "protest" may have its full weight. It is, of course, useless to think of deceiving any shrewd business men, either by "talking up" or "talking down" the size of the honey crop. The quantity, be it either large or small, offered for sale, decides the matter and makes the "exact truth" known.

The BEE JOURNAL has, on every every occasion, discouraged the idea that the business of keeping bees was fit for the lazy, invalids, etc., and does not believe in *tempting* any one to keep bees—but any *selfish* policy will in the end defeat itself.—Ed.]

For the American Bee Journal.

Bee-Keeping in Canada.

EDWARD MOORE.

Last fall I put 3 hives of bees into a box, packed with sawdust, but not packed as I would like, my means being very limited, and, at the proper time for packing, I was working, and could not attend to the bees. In the spring, when I opened the box, one colony was dead, and the other two very weak in numbers. The first opportunity I had, I united them, and the first flight they had, I saw they had the dysentery badly, but I allowed them a few flights. They were lively and active, and soon overcame that. Later I searched 2 or 3 times for the queen, but could see none; seeing hybrid queens advertised for sale, I thought I could do no better, so I sent for one, and received it all right. Taking the netting off the little hole of the queen's cage, I plugged it up with beeswax, and laid it on the top of the frames; sometime after, on looking, I saw the wax was gone, so was the queen. I closed up the hive. (It was on the 14th of June I received the queen.) As they were so weak in the spring, I expected no swarm this summer, but on July 3, they swarmed, and by appearances would more than fill a gallon measure; so there must have been a queen, for had the queen I put on the frames been received at once, and begun to lay immediately, the earliest hatched could not have been before the 5th; besides the queen was a hybrid. To-day, July 12, I had a second swarm, considerably

smaller than the first, but enough to build up well before the fall.

Soon after warm weather set in, we had, and continue to have, considerable rain, so much so that a great deal of the cultivated land is like a marsh, and we have rain the greater part of the time, both day and night. There is an abundance of clover bloom, but the bees can get out but little, and, I suppose, that if they could, there would be but little nectar to gather, but we must hope for better things before long.

We have had a few warm dry days, and the subjects of this correspondence are as busy as bees. July 12, was warm and cloudy, still not by any means entirely overcast. Toward evening it darkened down, began to thunder, with heavy rain again, and is a critical time yet, I fear, for honey gathering.

On Saturday 14th, I had another small swarm. I think of acting as near as I can up to the instructions of Prof. Cook with respect to rearing a queen or two, to have ready if needed. Barrie, Ont., July 14, 1883.

For the American Bee Journal.

A Word to Iowa Bee-Keepers.

O. CLUTE.

By invitation of the Executive Committee, I attended the annual winter meeting of the Iowa Agricultural Society, last January, in Des Moines, and gave a lecture on "Modern bee-keeping." The audience was large, and seemed much interested in the subject.

I was requested also to attend a business meeting of the Executive Committee, and to make a statement as to the importance and prospects of the bee-keeping industry, and of the help the Agricultural Society could give in fostering and developing it. I found the committee to be composed of courteous gentlemen, who were quite willing to do anything reasonable. They asked me to make out a list of premiums to be offered at the State Fair, this fall. It seemed unwise for our infant industry to make too large a demand at first, so I made out a modest and yet honorable list, and submitted it. They adopted it at once. I can see now that it is by no means perfect, yet it will do for a beginning. If the parties interested in bee-keeping will come out in force, and make a good exhibit, we can have a better list of premiums another year. The premiums offered for this year are as follows:

CLASS NO. 128.

Bees, Bee Products and Bee-Keeping Implements.

	1st. Prem.	2d. Prem.
Best bees in observatory hives.....	\$3 00	\$2 00
Best and largest display of different races of bees...	5 00	2 00
Best comb honey, white clover.....	5 00	2 00
Best comb honey, linden..	5 00	2 00
Best comb honey, fall flowers.....	5 00	2 00

Best and largest display of comb honey.....	10 00	5 00
Best extracted honey, white clover.....	5 00	2 00
Best extracted honey, linden	5 00	2 00
Best extracted honey, fall flowers.....	5 00	2 00
Best and largest display of extracted honey.....	10 00	5 00
Best hive for summer.....	2 00	1 00
Best hive for out-door wintering.....	2 00	1 00
Best honey extractor.....	1 00	
Best bee smoker.....	50	
Best and largest display of bee keeping implements	5 00	2 00
Best comb foundation for brood combs.....	2 00	1 00
Best comb foundation for surplus comb honey.....	2 00	1 00
Best display of honey plants	3 00	2 00

NOTE.—The award of the judge or committee on bee products will be on a scale of 20 points of perfection, as follows: Color 5; quality (taste) 5; neatness of packages 5; and general advantage to purchasers, including facility for handling, 5.

I have examined somewhat carefully the premium lists of many of the State Agricultural Societies, and there is, I think, but one that offers a better list of premiums to bee-keepers. In most cases the premiums are so insignificant as to repel any bee-keeper who respects his calling. The bee-keepers of Iowa should respond to this generous treatment from our Society by coming out to the State Fair in large numbers, and exhibiting their products. Let us show to the State the beauty, the excellence, and the importance of our products.

While this word is addressed especially to the bee-keepers of Iowa, it must not be forgotten that our noble State throws its gates open to all. Competition in all departments is open to the world. All bee-keepers living outside of Iowa will be cordially welcome to the Fair, and their exhibits will be on a par with those from Iowa. It is hoped that many bee-keepers from adjacent States will come and help us.

Iowa is most excellently adapted to the production of honey. Undoubtedly this industry will rapidly develop in importance. If all the newspapers in Iowa will print this article, they will assist in furthering a new business which will soon assume large proportions, and will benefit every section of the State.

Iowa City, Iowa, July 25, 1883.

☞ We have organized a bee keepers' association at Waco, Texas, known as the "State Central Bee-Keepers' Association." Please give notice in the BEE JOURNAL.

J. W. GUYTON, Sec.

Waco, Texas, July 21, 1883.

☞ The summer meeting of the Cortland, N. Y., Union Bee-Keeper's Association, will be held at Cortland, N. Y., on Tuesday, Aug. 14, 1883.

M. C. BEAN, Sec.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Tiering up the Sections.

Will Mr. James Heddon please answer through the BEE JOURNAL the following questions:

1. What is the cause of bees making drone brood in the sections or boxes above the brood-chamber, on the old colonies, before swarming?

2. Is there any arrangement for putting on tiers of sections, more than one high, so that you can see when the sections are full, without raising up frames?

3. How many tiers high do you think right for a very strong colony?

JAMES SHORTT.

Oak Centre, Wis., July 19, 1883.

ANSWERS.—1. Bees are more desirous of producing drones just before swarming, as they at that time anticipate their immediate use. Drone or store comb has large sized cells, and they are quite apt to build this kind of comb in surplus sections where full pieces of foundation are not used; more especially if there is little drone comb in the brood chamber, which would surely be the case if full sheets of foundation were used there.

2. We use a case of our own peculiar style, which takes one tier of sections. We use this three and sometimes four tiers, or cases, high. To examine the case we remove the cover, and then one case after another, looking into their tops and bottoms. We find this much simpler and easier than any methods, using glass.

3. Answered above.

Italian Bees Turned Black.

What is the cause of my bees changing from Italian to black? Last April, I bought a colony of Italian bees. About the first of June I began to see a few black bees in the colony. To-day, July 16, you cannot see an Italian bee, or one that looks like one. The colony has not swarmed yet. I keep a small apiary of bees, mostly black; they are doing splendidly. I am more than pleased with the BEE JOURNAL. A. P. CHAPIN.

Fenton, Mich., July 16, 1883.

ANSWER.—In reply to your question, I would say that your queen died in the spring. The colony by some means or other became possessed of another. It would seem as though your new queen would produce hybrid bees containing some yellow bands, provided they had reared her from the one deceased, which you bought. It may be barely possible that a black

queen entered the hive, and became the reigning queen. I can hardly account for so sudden and radical a change, in any other way.

Heddon Rack.

I see in the last number of the BEE JOURNAL, page 357, that Mr. W. H. Harmer likes the Heddon section rack, and thinks the broad frames will soon be a thing of the past. What kind of section rack does Mr. Heddon use? Does he use the Langstroth hive? Is Mr. Heddon's rack suitable for both one and two-pound sections? Please answer in the BEE JOURNAL.

L. FATZINGER.

Janesville, Wis., July 22, 1883.

ANSWER.—In answer to the above question, I will refer Mr. F. to page 659 of the BEE JOURNAL for 1882.

The case represented is for one-pound sections, and the same plan is equally well adapted for sections of other sizes.

Transferring Bees from a Box.

Will it be advisable to take a swarm of bees out of a store box and put them in a hive at this time? The bees swarmed on June 9, and have built the box half full. Please let me know if I can do it and not disturb the bees.

GEO. D. RANDENEUSH.

ANSWER.—It is better for the inexperienced to do their transferring in the latter part of May or fore part of June. The harder and stiffer the combs, the better. Still, if properly done, there is no chance of failure in transferring your bees at this time of the year, and new swarms at that, upon the plan given in last week's BEE JOURNAL, page 367.

Moving Bees.

Living in a village, my bees annoy the grocers, and also people in their houses, when flowers fail. Is there any remedy but to move them out of town, if so what? If moved, how far must I take them, not to suffer loss of bees, by removal? Will Mr. Heddon please answer in the Weekly BEE JOURNAL.

J. E. FULLER.

Homer, N. Y., July 23, 1883.

ANSWER.—I am not one of those who believe so little in the rights of apiarists and so much in the rights of others as some bee-keepers do; but leaving the opposing rights out of the question, I believe it would well pay you to move your bees out of town, and that is the only practical remedy. I can move my whole apiary at any time of year from one rod to ten miles or over, without any loss resulting. Twice I have moved my whole stock about ten rods, once three-quarters of a mile, and all went well. I will, in the near future, in an article in this paper, tell you how I proceed.

Driving Bees.

I have watched the bees for my father 27 years ago, sometimes as late as August, for swarms. I have since learned that the heat of the season has more to do with their clustering on the outside of the hive than a propensity of swarming, especially so late in the season. About 15 years ago I bought my first colony of bees. I was a reader of the AMERICAN BEE JOURNAL for a few years, when printed in Washington, D. C. When I learned that it had become a weekly journal, I subscribed for it again, and I expect to take it as long as I have one colony of bees. With one or two exceptions, I never wrote a line for it or any other bee paper. As a goodly number of our professed bee-keepers give us their best ideas and new discoveries, I thought I would write a few lines and let the bee fraternity discuss what I believe to be entirely new, at least I never saw a line on the subject. I would like to apply to a practical use a discovery I made. It is this: I succeeded in making a number of swarms to come out of the parent colonies like a natural swarm does. I have done it as late in the day as 4 o'clock. By applying my process they swarm and cluster as any natural swarm does. I would like Mr. Heddon to consider this, and give the readers of the BEE JOURNAL the advantages that could be derived from it. I now have 78 colonies—spring count 25. Most of them in the surplus boxes. I use side and top surplus arrangement. I am not experienced in extracting, but will try it this week. I use a frame 11x12, which, I think, is 1 or 2 inches too deep. I believe a frame 9 inches deep by 12 long about the right size. I wintered on the summer stands last winter, and lost 60 colonies. I blame myself (as I believe all who lose heavily ought to) for losing so many, because I did not give them the proper winter protection. Allow me, in this connection, to ask whether there is among your many readers a person who has ever driven a swarm of bees as mentioned in this item.

J. R. ROENUCK.

Burton City, Ohio, July 14, 1883.

ANSWER.—Any cheap and practical method by which a colony can be made to cast a swarm at will, would be of great value to the fraternity.

In answer to your last question, I will say that several bee-keepers have reported causing their bees to swarm by inserting a queen-cell in the hive. This result, however, is only a possible one, and cannot be relied upon with any degree of certainty, and, undoubtedly, is entirely impracticable. As far as the size of your frame is concerned, I agree with you that it is too deep, and will say that could I now inaugurate an universal frame, I would, for one or two quite important reasons, make it not over seven inches deep, which is two inches shallower,

and I would have it a little longer than the Langstroth frame. But experience in thousands of cases, and in hundreds of apiaries, has demonstrated beyond all doubt, that there is less importance regarding the size of frame as adapted to breeding, wintering and surplus honey-storing than that we have one and the same size frame, in general use. I am always ready and anxious to put to the test all new methods which bid fair to prove valuable adjuncts to the science of apiculture. I would like to know of your method.

SELECTIONS FROM OUR LETTER BOX

Keeping the Colonies Strong.

The basswood has never yielded more honey in one season than this. My hives are 12x22 inches, and 13 inches deep, inside measure. About 12 frames 11 inches square fill a hive. On top of this I put a hive made for wide frames, holding 8 one-pound sections. I keep my colonies very strong, so that they will fill sections rapidly. Perhaps you would like to know how I keep them so strong. Some time before the basswood bloomed, the bees were gaining in stores from white clover; I examined some of the strongest, and found about 6 or 7 queen cells started. I destroyed all I could find in each hive, thinking this would prevent them from swarming for a while; but they built other cells immediately. Then the basswood commenced to bloom and they wanted to swarm; I let about a gallon of bees go out with the queen. I then shut the hive up until the swarming fever was over; I kept destroying all the queen cells in the old hive, except one, until the brood was too old to produce queens. The amount of bees which went with the queen was hardly missed from the old colony. The swarm which was hived I strengthen with hatching brood, when the rush of honey-gathering is over. A part of my hives have just one story, or at least without the sections to extract from, and, after doing so, I keep some of the whitest comb which has no brood in it, take out full sections and fill empty ones with this comb, and put in the place of the full ones.

WICKLIFFE FISHER.

Handler, O., July 26, 1883.

Never Saw the Like Before.

My 27 colonies in the spring have given 2,700 lbs. of extracted and some comb honey, besides increasing to 65 colonies and some nuclei. Basswood is now in full bloom. I never saw the like in the 18 years I have been in Minnesota.

H. H. ROSEBROCK.

Owatonna, Minn., July 25, 1883.

Queen Laying in the Sections.

My spring yield of honey is over. I took out the last on the latter part of June. The amount from my 60 colonies is 3,000 pounds of extracted honey. I will probably get half as much more in the fall. Is there any way to restrain the bees from making brood in the upper story? My bees seem to have a particular fancy for that this season. Please tell me about the Bokhara clover, whether or not it is very desirable as a honey plant.

M. M. LINDSAY.

Fulton, Tenn., July 24, 1882.

[Some use what is called queen excluders—sheets of zinc with holes large enough to admit the workers, but through which the queen cannot pass. Bokhara is the imported sweet clover, and is an excellent honey-producer.—ED.]

Best Honey Harvest for Years.

We have had the best honey harvest here for years. The bees are just booming. It is in fact the best we ever had.

H. C. WHITE.

Madison, Ind., July 17, 1883.

Troubles of a Beginner.

The flood of last winter left me with but 3 colonies of bees. They each swarmed about the middle of June; in 7 days I listened for the piping of the queen, and heard it in one of the hives, but not in the others. A swarm followed, and the piping went on until 4 swarms came off. In one hive, that night, the piping was as loud as ever, but no swarm followed, nor have I heard any piping since. The night after, the fourth swarm came out, but there was no piping or swarming in the others. They put surplus in the upper story (box hives). My difficulty was this, in hiving a swarm that came off on June 16, the cluster was low, on a grape vine. I set a Langstroth hive on the ground and shook the bees down, but they clustered on the hive in front, and refused to enter. I brushed them down, and repeatedly changed the hive, took out some of the frames, but to no purpose; there they staid all night, and got the benefit of a drenching shower. On the morning of the 17th, I sent for a neighbor of greater experience, not liking to lose the bees (a very large swarm). He put in the frames, also put on the boxes, and went to work with smoker and stick, working faithfully in the rain for an hour, and literally drove them in. I carried them to the stand and had no further trouble. But, on the 9th inst., I took off the boxes and found a very few boxes of nice clover honey, the rest were filled with brood in all stages, young bees, sealed and unsealed brood, and cells with eggs just deposited. Cells that from their color seemed to have been used before, and from which I am convinced young bees had come very lately. After taking the combs out, I watched them for an hour or two, and was rewarded by seeing bee after bee biting

off the cap and emerging from their cells. I do not know whether I could have saved any of this brood, by placing the combs under a box hive, or whether I was all wrong in putting on the boxes at the start, and as the bees must have entered the boxes when hived (only 21 days intervening), have I probably lost the queen, and how am I to know? We are having a famous honey season; white clover covers the land, and bees work prodigiously.

THOS. MARTIN.

Coal Valley, Ill., July 10, 1883.

[Had you given the swarm sheets of foundation in the brood-chamber, they would not have gone up to the surplus arrangement to build comb, and use it for brood-rearing. If no comb foundation was given the swarm when hived, or old combs, the surplus arrangement should not have been put on. If the queen was "lost," where did the brood come from?—ED.]

White Honey Harvest Short.

Basswood, which is very abundant in our vicinity, has just gone out of bloom. From some cause, there was not one blossom to many thousands last year, when the weather was favorable but a part of the time, so the yield has been very light from it, this year. White clover has never bloomed so abundantly with us, as it has this season; but the weather has been too cold and wet to give us much from that source, consequently our white honey harvest will be very short. White clover is still in bloom, and we may get a small amount from it yet. We have extracted 2,000 pounds, and have taken 400 pounds of comb honey, and still have in the hives enough to make the former 2,500, and the latter 500 or 600 pounds, from 100 colonies, in splendid condition. Last season we got nearly twice the amount from 50 colonies. We would like to inquire of those having had experience with Alsike clover, if cattle pastured upon it are as liable to become bloated as upon red clover. If the Alsike is free from this objection, it can be largely introduced among the farmers, and will be a great benefit to bee-keepers.

A. J. HATFIELD & SON.

New Carlisle, Ind., July 24, 1883.

How I Build Up My Colonies.

My bees are just booming, and have been most of the time since white clover came in, some 4 or 5 weeks ago, and it looks now as if it would last well for 2 or 3 weeks yet. From our present prospects, we will get as good a yield as we did last season. I began the spring with 11 colonies, all in fair condition except one which proved to be queenless; but I kept it going by giving it brood from other colonies, until a new queen was reared, so now it is one of my best. I have bees in 23 hives, but do not count all true colonies until the queen is laying. I make my increase by dividing on the nuclei plan, which I like best, for it leaves the main colonies strong for

making new comb, rearing brood, and storing surplus honey. I usually get nice comb built (when I do not have foundation), by putting in 2 or 3 empty frames at a time, near the center of each colony, one frame in a place. By this plan I build up my young colonies gradually, without drawing much on the old ones. Here I will state how I prepare brood sections for the Langstroth hive, so that they hold either natural comb or comb foundation, without sagging or breaking out when handling the combs, either in the extractor or otherwise. I take good broom wire and stretch it tightly across the middle of the section. To do this, I make a hole in the end pieces, put the wire through, fasten one end, and draw it tightly and fasten it, before cutting the wire. Fasten the ends by bending over and twisting around the wire, and I find the bees nearly always build the comb with the wire in the center, with perfect cells on each side. I filled several sections prepared this way last season, with foundation, and it all proved a success without trouble. After fastening at the top, lightly press the wire into the sheet of foundation, and the bees will draw it out alike on both sides. In sections fixed in this way, you will always find that the comb is strong and will stay to its place. I have had them in use several years. From my 11 colonies about two weeks ago, I extracted 200 lbs. of fine white clover honey, and I can take about the same now, and about 100 lbs. of fine comb honey in two-pound sections.

J. W. SANDERS.

Le Grand, Iowa, July 20, 1883.

Abundance of Rain.

Rain still reigns in this neighborhood. We have had rain nearly every day this month, until about a week ago, when it ended with the heaviest storm of the season, overflowing the banks of the river, and caused great destruction and loss of life and property in the parts of this city lying low. One bee-keeper in this city had to carry his bees upon the top of his house; another saved only one colony out of his whole yard, being more fortunate than some others who lost every colony. I am happy to say mine are doing very well, and I am satisfied they will pay me a very good interest on my investment. Basswood has started to bloom, and clover is still in blossom; so if we have two or three weeks of dry weather now, we will be all right until fall flowers appear.

W. H. WESTON.

London, Ont., July 20, 1883.

Giant Ladies' Slipper as a Honey Plant.

I see that the German word, "Riesen Balsamine" was translated wrong on page 355. It should have been the *Giant Ladies' Slipper*.

L. KNORR, M. D.

Savannah, Ga., July 22, 1883.

[If any of our readers know of this plant yielding honey in America, we should be pleased to hear from them on the subject.—ED.]

Excessive Swarming.

It has been out of the question to keep bees from swarming. The weather has been too wet and cold, all through the white clover season; with only enough of sunshine to give the bees a chance to swarm; swarm they would, and swarm they did. Pasturage has been good all the spring and summer, so far, but the weather has been so bad that they could not gather the crop, which has been most abundant, if it could have been saved. Basswood opened the 15th, and would have given us a large surplus, had the weather been favorable; bees are very strong, and would do well if they could.

A. W. OSBURN.

Water Valley, N. Y., July 23, 1883.

Sweet Clover, etc.

I enclose samples of honey plants. Please give me the name of plant No. 1, and also state whether it is honey-producing. My bees have not found it yet, as it grows by the kitchen door, and they never come about the house. Is No. 2 the famous Mollie O'Large's honey plant, that we read so much about? Is smartweed and heart's-ease the same plant? Please answer in the BEE JOURNAL.

Mrs. J. N. HEATER.

Columbus, Neb., July 2, 1883.

[Number 1 is sweet clover (*Melilotus officinalis*), a well-known honey plant, and for its large and long continued nectar-product, very justly esteemed by apiarists. Another species much like the present one, has white flowers, while these are yellow. Both are natives of Europe, but are now widely disseminated throughout our country, and spontaneously (as would appear) spring up about the yards, roadsides and waste places anywhere. They are biennial plants, flowering or not the first year, according to the earliness, vigor, etc., of the seedling, and the length of the season, but springing up from the root the second year, and making rapid and large growth with an abundance of flowers, each of which is richly filled with honey of excellent quality. The plants are very hardy, and in most places propagate themselves sufficiently to keep up the supply. The first part of the generic name, *Mel*, means honey; so conspicuous, this substance seemed to be to Tournefort, the French botanist, as he examined and named the plant.

Now comes another side to the story. Only last week an appeal came from Livingston County, Ill., for information as to how to exterminate this sweet clover from the roadsides, the officer in charge finding it a veritable nuisance as a weed. Neither is this the first request of the kind

that has come to your correspondent from the region of country southwest from Chicago, within a radius of a hundred miles. Cattle do not commonly eat the plant, and no enemies among the insect tribe appear to follow it. The long, hard stems, with open foliage, make a poor substitute for many better plants which are crowded out in the special localities where this clover prominently thrives. This again opens up a very interesting, and in many ways, important question, much too intricate and involved, however, to be entered upon here, except as a simple statement—the question of the peculiar growth of certain plants in certain regions.

We used to have an idea that plants succeeded best in their native country, or at any rate in places most nearly resembling in soil, climate, etc., the original home of the species, but this is by no means the fact. Our worst weeds are such from their vigor and abundant reproductive powers, but nearly all these worst ones are importations from abroad, largely from across the ocean. On the other hand, some American plants, not specially obnoxious at home, are the pests of the fields, gardens, etc., of other countries. Our evening primrose is well-nigh an occupant of the whole land area of the temperate zones, sometimes scattered and scarcely noticeable, sometimes pestiferous as a weed. The same fact may be noted in regard to the plant growth in different parts of our country. In central Illinois Canada thistles do not thrive, no seed at all is produced. Those pests of the eastern pastures and meadows, "hard-hack" and "white weed," are rarely seen in the West, and if introduced, more rarely maintain their unenviable reputation. Any one may multiply these examples, but it is not so easy to answer why such peculiarities exist. Without attempting it here in any way, attention is called to the importance of proper knowledge in this respect, when introducing or harboring plants strange to the vicinity. A pest may be kept out or readily exterminated perhaps at first, which, after a time, becomes a continual nuisance in spite of efforts at eradication. The bee men are blamed in the locality referred to for the existence there of sweet clover, whether justly or not is another matter.

Number 2 belongs to the mustard family, and seems to be a *Dentaria*.

The specimen is not sufficiently developed to permit accurate determination.

The plants usually called smartweed and heart's-ease are not the same species, though similar in appearance, and belong to the same botanical genus (*Polygonum*). The former—there are several of them—have a sharp or peppery taste, the latter is quite free from this property, and contains a gland mucilage not found in the other. When, however, bee-keepers speak of the product from "smartweed" the non-acrid species of *Polygonum* are meant, for these are by far the best honey plants.—T. J. BURRILL, Champaign, Ill.

Width of Sections.

In reply to G. H. Denman (see page 363), I would say that my sections were a sixteenth less than two inches wide, and in racks holding 21 sections.

L. C. WHITING.

East Saginaw, Mich., July 20, 1883.

Gibson Co., (Tenn.) Association.

Too much rain this season for a good flow of honey. The crop is almost a failure, in this section. I will get some more yet, but in all that I get from the spring harvest will be about 1,500 pounds of comb honey. My bees are bringing in pollen rapidly now, and rearing bees for the fall crop, and with favorable weather we may expect a good fall crop of honey. Bee-keepers are getting somewhat more interested in bees, in this country, than before; and have organized the "Gibson County Bee-keepers' Association," a report of which you will get next week. The BEE JOURNAL comes regularly, and is a welcome visitor to Honey Hill apiary.

J. W. HOWELL.

Kenton, Tenn., July 17, 1883.

Poor Honey Prospect in New York.

We had a hard fight to get our bees through the cold spring, and many colonies fell by the way. Since then an almost continual rain blighted our good prospects for a large yield of honey. We had a good show of white clover, but heavy rains prevented the bees from gathering much honey from it. Basswood has helped bees to fill the brood-chambers some, but gave only a little surplus honey. The result is, there is but very little surplus honey in this section, up to this date. We may get some fall honey.

R. BACON.

Verona, N. Y., July 24, 1883.

Basswood Come and Gone.

Basswood began to bloom 10 days ago, and it is now gone. Sumac is in its prime, and will last for 3 weeks yet. I have had about 50 pounds of surplus so far, on an average, per colony, and more is nearly ready to take away.

H. L. JEFFREY.

Washington Depot, Ct., July 23, 1883.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price still lower, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00, or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Do not send coins in a letter. It is dangerous and increases the postage unnecessarily. Always send postage stamps, for fractions of a dollar, and, if you can get them—one-cent stamps; if not, any denomination of postage stamps will do.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quimby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper, shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter, on your label, notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a statement of account every week.

May we ask you, dear reader, to speak a good word for the BEE JOURNAL to neighbors who keep bees, and send on at least one new subscription with your own? Our premium, "Bees and Honey," in cloth, for one new subscriber to the Weekly, or two for the Monthly, besides your own subscription to either edition, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

Bingham Smoker Corner.

Large Smokers need wide shields. Bingham's have them, and springs that do not rust and break, and bellows that sparks and smoke do not enter. The Conqueror has all improvements made to date, and a 3x7 inch stove, and 5x7 inch bellows. Sent post-paid for \$1.75. Address,

BINGHAM & HETHERINGTON,

Abronia Mich.

The Very Best.

The Bingham "Conqueror" smoker is the very best thing I have tried in that line.

M. M. LINDSAY.

Fulton, Tenn., July 24, 1883.

All Excelling.—Messrs. Bingham & Hetherington, Dear Sirs:—I am now selling your Smokers almost exclusively. You are excelling yourselves in smokers all the time.

Respectfully, J. G. TAYLOR.

Austin, Texas, May 10, 1883.

Cyprians Conquered.

All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am "boss." Bingham's "Conqueror Smoker" did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham.

G. M. DOOLITTLE.

Borodino, N. Y., Aug. 15, 1882.

During the following three months, Bingham Smokers will be sent post-paid, per mail, on receipt of the following prices:

The "Doctor" (wide shield)—3½ in. fire tube, \$2.00
 The Conqueror (wide shield)—3 in. fire tube, 1.75
 Large (wide shield)—2½ in. fire tube, 1.50
 Extra (wide shield)—2 in. fire tube, 1.25
 Plain (nar. shield)—2 in. fire tube, 1.00
 Little Wonder (nar. shield)—1¾ in. fire tube, .65
 Bingham & Hetherington Uncapping Knife, 1.15

With thanks for letters of encouragement, and the absence of complaining ones, we tender to our thirty-five thousand patrons our best wishes.

Very Respectfully Yours,

BINGHAM & HETHERINGTON.

Abronia, Mich., June 1, 1883.

The New York and Lake City Mining Company.

A prominent engineer, who is well acquainted with Mines in all parts of Colorado, was recently invited to examine the property of this Company. He gave it as his opinion, and he is perfectly disinterested, that the property is the richest he had ever seen, and is worth \$5,000,000.—*Adv.*

Advertisers' Opinion.

The queen business is *rushing*, and we think the BEE JOURNAL deserves much credit as an advertising medium.

BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS C. NEWMAN.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

It contains 160 profusely illustrated pages, in "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most honey in its best and most attractive condition.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—Farmer, Lancaster, Pa.

PRICE—Bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

THOMAS G. NEWMAN,

THE AMERICAN BEE JOURNAL

ESTABLISHED
IN 1861

VOL. XIX.

CHICAGO, ILL., AUGUST 8, 1883.

No. 32.

THE AMERICAN
BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

The Hive and Frame Controversy.

The BEE JOURNAL for July 25, contained an article by Dr. E. B. Southwick, setting forth the advantages of square frame hives, and one from Mr. G. W. Demaree, giving the arguments in favor of rectangular frames.

It was not the intention of the editor of the BEE JOURNAL to take any part in the argument, and had he not been singled out for a personal thrust by Dr. Southwick, no word of comment would have been made.

Our remarks on page 365 were soothing and courteous, but even kind words seem to have irritated him.

After giving positive proof of the correctness of Mr. Root's assertion that "more shallow-frame [Langstroth] hives were in use than all others put together," we remarked as follows:

We do not endorse the opinions of Mr. Root, Dr. Southwick, "or any other man," unless they commend themselves to our judgment! But we hope never to indulge in uncharitable words or feelings against any one for a frank statement or opinion, and, hence, we shall exercise this *generosity* towards Dr. Southwick, when he states that "not $\frac{1}{4}$ of those that use movable frames, use what is to-day considered the Langstroth frame, and that number is silently growing less!" The Doctor's statement is so far from the facts, as settled by the only statistics available, that we have here an excellent opportunity to let "charity cover a multitude" of errors!

The above was intended to pacify, but it evidently had the opposite effect; at least we should think so, by the following from Dr. Southwick:

MR. EDITOR:—On page 369, of the BEE JOURNAL, I notice an error that puts me in a rather odd position, in the last column near the bottom. It

reads thus: "Containing white clover comb, made to order by my bees, last fall." Who ever heard of white clover in the fall? The word *clover* should be *drome*, to make sense.

I see in your editorial that you allow one more article from each on the subject; thanks for your generosity, but that was not in my proposal, as I consider these long discussions which appear in the BEE JOURNAL, the greatest bore the readers have to endure. I, therefore, made my proposition so as to avoid anything like a discussion. Mr. Demaree can take the advantage of your generosity if he chooses, but I respectfully decline.

I did not expect that you would attempt to prejudice the reader against me and my article, before they had a chance to read it, by trying to show that what I said I believed (not stated as you have it) was not the fact, and indicate to them that I did not believe what I wrote; that it was for fun, etc. I did hope to get two articles before the readers of the BEE JOURNAL, setting forth the qualities of the two frames without any editorial influence accompanying them, but your criticism on Doolittle's article, and now on mine, convince me that I cannot. Mr. Demaree is fully competent for his side of the question, and the Langstroth frame men certainly will not suffer from my incompetency, and if the two articles could have gone out untrameled, an impartial decision might have been arrived at by some.

As I have done with the frame question, you will, no doubt, allow me a little space to reply to your editorial, and let me first state that I mean every word that I say, and just what I say.

If I understand you correctly, you endorse Mr. Root's statement, by speaking of its correctness being settled, etc., and, as your proof, you bring forward statistics, and state they were gotten from reports of the readers of the BEE JOURNAL. In order to get at the reliability of statistics, we must go to the source from which they were obtained; you say, from the readers of the BEE JOURNAL; now, as the BEE JOURNAL has advocated, and always recommended the use of the Langstroth frame, is it not reasonable to conclude that a much larger number in proportion would be of that faith than where some other, or none at all, were recommended? Again, what portion of the bee-keepers read the BEE JOURNAL?

If one in twenty took it, I think the number of your subscribers would be increased; but we will say one in ten read it, and now what portion of its readers made a report? I think if you count your subscribers, and then your reports, you will find that the reports would have to be increased four or five times before it would equal the other, but we will admit that one-half report, and which one-half is that? I think it much more likely that the one-half that has advised with you, and obey you in using the Langstroth frame, would be the first to report; while such as myself and many others would consider the utter impossibility of getting anything reliable from it, would pay no attention to it. Now, as we admit one-tenth of the bee-keepers read the BEE JOURNAL, and one-half of them reported (I think I have been very generous in so doing), we have one-twentieth that reported, and as nearly one-half of them use the box hive, we have a little more than one-fortieth of the bee-keepers to use for statistics, and those are they that you have brought up and educated in the theory that the Langstroth frame is the "*ne plus ultra*" of all frames, and as you find a majority of these use the Langstroth frame, you declare that there is a majority in the whole United States. As well might Brigham Young have declared that there were more Mormons than all other religions put together, just because there were in Utah!

I think I discover a twinkle of fun behind those glasses, and an expression on your face that says: "Ain't I soft-soaping the Doctor good, with my statistics?" Oh my; what statistics!

In the last column you say you will "exercise generosity." Now, Mr. Editor, just hold on; keep your generosity until you can quote my article as it is. If you made that quotation, thinking what you did, it is downright meanness, after what I had written a few lines before. I hope the readers will take the article and not the quotation. You say that "my statement is so far from facts." Now, if I have made a statement that is not a fact, I am a liar, and I do not want it covered up with charity—that fertilizer of hypocrisy and rascality! That licenser of villainy, and all kinds of meanness! That which covers up a man's sins that he may commit more! No, do not cover up my errors with charity. You hint that

they are many—expose them to the world, that others seeing may avoid them, and I, knowing them, may improve by such knowledge. You say my excuse for A. I. Root "is exceedingly thin." Well, it is the thickest I could find, and if that does not excuse him, I do not know what will. But it does not begin to be as *thin* as your statistics!

Now, as I understand you to convey the idea to your readers, it is about thus: "The Doctor's statements are far from the facts; his errors are multitudinous; but he is jolly fellow and we won't mention them; he does not believe half he writes!" Why do you throw out these hints? Do you think you readers are fools, and cannot understand as well as you? Now, I defy you, or any one else, to show that one statement that I have made in that article is not in accordance with facts. What I state to be facts are, with me, known facts; and what I believe are not known facts to me, for if they were known facts, they would be no longer subjects of belief, but of actual knowledge. I explained this in my article, I thought, so plain that "a wayfaring man, though a fool, need not err therein." I do not think I ought to blame you, for it appears to be a second nature for Langstroth men to state what they think, as actual facts; but when you lug me into that association, I assure you that it hurts, for if "jolly" I have some regard for the truth of what I say.

Now, I will give the reasons for believing what I said I believed, and as you think so much of statistics, I will give some in that form. There are, in this vicinity, 36 bee-keepers that I know of; and I think there are none that I do not know, and these all use frame hives; there is not a box-hive among them. Out of this number 3 claim to use the Langstroth hive; one of these has increased the height of his hive so as to use a frame 12 inches deep; another has made his frames to go crosswise of the hive; the other is a man that knows but little about bee-keeping, and gets another man to take care of them, and that man condemns the Langstroth hive every time he has anything to do with it.

Now the statistics: 36 bee men, 3 Langstroth hive men, 33 that use hives taking the square frames, 2 of the Langstroth hive men have changed their frames from the long and shallow to the short and deep frame, so these 2 will have to be reckoned on the side of the square frame, which will make our statistics foot up thus: 35 square frame men, 1 shallow frame man, 36 in all. These statistics, I claim, are much more reliable than yours, for they come from a more enlightened set of men, as shown by their having no old box hives; while almost half of the community from which you get your information are back in the heathen darkness and ignorance of the old box hive and gum.

Again, I read a report a short time ago of a convention, and I think there were about 30 present, and only 2 used

the Langstroth frame, but say there were 24 present and 3 used the Langstroth frame, their statistics would show only $\frac{1}{8}$ using the Langstroth frame, which is only half of what I had it. Now, do not these statistics "settle it" that the Langstroth frame is a small minority, and that minority is gradually growing less? and the neglect of the square frame neighbor, who cares for the Langstroth frame; many bees would soon drive the last one out to sea.

Another reason is, I think, many of our oldest, most experienced, most scientific, and most successful bee men who use and recommend the square frame, say but little about it; but I have frequently noticed that the greatest noise generally comes from the biggest fools. I might add many more reasons for my belief, but I do not wish to occupy the space, nor have I the time at present.

Mr. Demaree will please accept my thanks for the candor he has exhibited in his article. He has written me that he is satisfied that he "holds the fort." I wrote him there was but little danger that he would not hold it, when he has so strong a corps of editors to guard it; but I advised him to withdraw while his laurels were fresh, lest the people "arise in their might," demolish the fort, destroy him and his guard, and tread his laurels in the mud. Now, hoping that what has been said may not disturb our former friendship, I remain yours truly,
E. B. SOUTHWICK.

It is *useless* to attempt a discussion of any subject, when a mild and kindly-worded argument calls out such a *fierce* reply as the foregoing. Such *harsh* words as liar, fools, downright meanness, hypocrisy, rascality, villianry, etc., are not calculated to induce an impartial decision of any question!

The discussion of the comparative merits of the "square and rectangular frame hives" will, therefore, cease, for the present, in the BEE JOURNAL, with the exception of one article from Mr. Demaree (if he should desire to reply) as promised, two weeks ago, and one from the Rev. L. L. Langstroth, which he is now preparing, by request. Our correspondents will please "take due notice, and govern themselves accordingly."

When it can be discussed impassionately will be time enough to resume—until then, let us take up some other questions, from a review of which some good may result.

☞ The summer meeting of the Cortland, N. Y., Union Bee-Keeper's Association, will be held at Cortland, N. Y., on Tuesday, Aug. 14, 1883.

M. C. BEAN, Sec.

☞ Articles for publication must be written on a separate piece of paper from items of business.

The National Convention.

The National Bee-Keepers' Association, will hold its Annual Convention in the City Hall and Council Chamber in the city of Toronto, on Tuesday, Wednesday and Thursday, the 18th, 19th and 20th days of September, during the second week of Canada's Great Fair. All the railroads in Canada will issue tickets during this week, good to return, up to Saturday night 22d, at single fare for the round trip. Special excursion rates will be arranged from various parts of the United States, of which due notice will be given. Those who intend being present may be kept posted on the latest excursion rates, etc., by addresssing me, and also that I may arrange hotel accommodation. Private lodgings will, if possible, be secured for those who desire it, and every effort will be made to make everybody comfortable. A grand meeting is anticipated.

D. A. JONES, President.

☞ Mr. E. T. Flanagan informs us that at the St. Louis Fair, the privilege has been granted of selling honey on the grounds, during the exhibition, to all bee-keepers that make a *first-class exhibit* and keep their exhibits intact. This will aid honey consumption very much, and should prevail at all fairs.

Fairs.—To any one exhibiting at Fairs, we will send samples of the BEE JOURNAL and a colored Poster, to aid in getting up a club. The Premiums we offer will pay them for so doing. For a club of 8 subscribers to the Monthly BEE JOURNAL, or 4 we will present Dzierzon's Rational Bee-Keeping, price \$2.00.

Postage on Queens to Canada.—On any package of merchandise sent to Canada, of 8 ounces or less, the postage is 10 cents. Queens, therefore, cannot be sent for less than 10 cents each. Canadians ordering queens from the United States, should add 10 cents for each queen, if they are to be sent by mail, for that extra 10 cents will usually eat up all the profits on queen bees, if they are reared as they should be.

☞ The pamphlet, "Honey, as Food and Medicine," is in such demand, that we find it necessary to print them in still larger quantities, and can, therefore, still further reduce the price, as noted on page 399. Let them be scattered like "autumn leaves," and the result, we feel sure, will fully reward honey-producers for both the labor and the small expense.

Local Convention Directory.

1883. *Time and Place of Meeting.*
- Aug. 14.—Cortland, N. Y. Union, at Cortland, N. Y.

- Oct.—Northern Ohio, at Norwalk, O.
S. F. Newman, Sec.
- Dec. 5-6, Michigan State, at Flint.
H. D. Cutting, Sec., Clinton, Mich.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

From Deep to Shallow Frames.

Mr. J. B. Mason, of Mechanics' Falls, Maine, gives the following reasons, in the *Home Farm*, for changing from the deep to the shallow frame:

My prejudices have for a long time led me to favor a deep frame, and so strong were they that I would not give the standard Langstroth frame a fair trial. This prejudice arose, I suppose, from accepting the theories of the opponents of the Langstroth frame, which theories seemed so plausible that I was led to accept them without proof, and adopt them as being absolutely correct. I suffered a large per cent. of loss with the deeper frames, but this I laid to various causes and any, as it proved, but the right one. At last, after seeing so many accounts from various sources of the success that disinterested beekeepers met with in using the standard Langstroth, I was led to try it, and as a matter of fact it proved a success with me. Now I claim to be honest in the matter of apiculture, and as I am not interested pecuniarily in the success of the Langstroth or any other frame, consequently I cannot be accused of self-interest in adopting it for myself or advising its use by others. I have in the last two years transferred over 50 colonies from the deep frames to the standard Langstroth, and packed away the old hives which are worthless to me, and as James Heddon said, two years ago, I think I have saved money by so doing, and to show how the tendency is for the Langstroth frame, I will say that out of over 70 orders in the State of Maine for bees, all but 4 were for the Langstroth frame.

Again, I have not as yet attained that profound knowledge of apiculture which would lead me to think that I know it all, and that no one can teach me anything; neither am I ashamed to admit errors, when by study and observation I find my previous opinions, deep-seated though they are, to be incorrect. I had a deep battle with myself before I was

willing to admit, to myself even, that the Langstroth frame would and did winter better than deeper ones, but the results in my own apiary, and not only in mine, but in apiaries generally throughout this State, forced me to change my mind, and having so changed, in justice to those who had been taught differently by me, caused me to give my new views to the public. So far from being changeable in matters of bee-culture, I have heretofore clung to my pre-conceived ideas with great tenacity, and have been led to change them only by proof of the most solid character. He who sticks to his opinions does well, but he who changes when he is fully proved in error does better, and I trust to always stand among those who are ready to give up an opinion when proved to be wrong.

Having stated my position and the reason that led me to change my views in regard to the relative merits of deep and shallow frames, I will say, that while all open-top, movable, sectional, hanging frames are Langstroth, and were fully covered by his patent, the term "L" frame, for convenience sake, was given to the particular form, that Mr. Langstroth advised; while those of different form were called after their originators.

Alley's Shipping Cage Food.—Mr. Henry Alley, of Wenham, Mass., has sent us a black queen and some bees in a cage supplied with his new kind of food. They came in excellent condition, and we returned them to him to see how they stand the journey of 2,000 miles. The food is soft, but does not run, and there is not the slightest chance for its "daubing the mails," and it does not have the disagreeable feature of crumbling and rattling about the cage. The bees ate it with the greatest avidity, and with apparent relish. We hope it will prove to "just the thing" we have long been wanting for use in shipping cages.

The Fremont, Mich., *Indicator* says: "George Hilton says you can take your dish to his apiary and get pure extracted honey for a shilling a pound. This is almost as cheap as the adulterated syrups of commerce, and a great deal better for the children." That is the way to say it. It gives health; not disease like the vile syrups! and yet costs no more than the adulterated trash!

The Rev. W. F. Clark, who went to Winnipeg, last summer, is about to return to the States, and possibly may locate in Chicago, as an attaché of the agricultural press here.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL.
Monday, 10 a. m., Aug. 6, 1883.

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The honey harvest in this neighborhood is over, and was very satisfactory every where. Large crops were produced in my immediate neighborhood of bulk extracted and comb honey, and our Kentucky neighbors seem to belong to that favored class of mortals with whom there is no such word as failure. While we had very poor seasons for 5 years in succession, they harvested medium to good crops every time, and this season eclipses all previous ones with them, in quantity. Their quality cannot be excelled. We have had very large arrivals, and, our commission houses being well supplied, the market is overstocked at the present.

There was almost no demand for the last 3 or 4 weeks for our small packages—1 and 2 lb. jars. We sell for table use, and there is a very slow demand for such quantities as are used in barrels for manufacturing purposes. Honey being pushed on the market in such quantities, is sold at all prices, and our friends have the best show in the world for running prices down to a point from which they may be hard to recover.

Our prices, of late, for extracted honey, have been 7@9c. on arrival, and for choice comb honey 14@16c.

BEESWAX—Has been in fair supply, and sold at 30@32c. for good, on arrival. CHAS. F. MUTH.

NEW YORK.

HONEY—We take pleasure in quoting the following prices on honey, obtainable in our market: Fancy white clover, 1 lb. sections (no glass) 20@21c; fancy white clover, 2 lb. sections (glassed) 18@20c; fair white clover, 1 and 2 lb. sections (glassed) 16@17c; fancy buckwheat, 1 lb. sections (no glass) 15c; fancy buckwheat, 2 lb. sections (glassed) 13@14c; ordinary buckwheat, 1 and 1 lb. sections (glassed) 11@13c; extracted clover honey in kegs or barrels 9@10c; extracted buckwheat honey in kegs or barrels 7@8c.

BEESWAX—Prime yellow beeswax 31@33c. H. K. & F. B. THURBER & Co.

CHICAGO.

HONEY—New crop of comb honey is being offered, and some sales of it have been made at 16@18c in 1 and 1½ frames. The receipts of extracted are liberal, and there is a good deal of complaint about unripe honey; consumers holding off. Market, 16@18c for white. Very little dark left, and some inquiry for it.

BEESWAX—36@38c. R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Gloomy accounts continue to be received from the Southern coast counties regarding the honey crop. In the region of Tulare there is a good yield. Some Tulare comb, crossed and mixed, was placed at 13@c., and extracted of the crop of 1881 sold at 7@c. White to extra white comb 16@20c; dark to good 10@13c; extracted, choice to extra white 7@9c; dark and candied 6@8c.

BEESWAX—Wholesale, 27@28c.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—New, in liberal offering, but little sold in quantities—held higher; extracted or strained at 7@8c, and comb at 16c. Lots in fancy packages bring more in a small way, while old and inferior sells less.

BEESWAX—Inactive and easy, at 27@28c.

W. T. ANDERSON & Co., 104 N. 3d Street.

CLEVELAND.

HONEY—There is a very good demand for new white honey at 18@20c. for 1 lb. sections; 2 lb. new 17@18c; old, 15@16c. No extracted has been received, and none seems wanted in our market.

BEESWAX—32@33c.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—We are now just commencing a new season, and the prospect is very bright. We are receiving letters from all over the country reporting an abundant supply. Our principal New England supply comes from J. E. Crane, who writes us that his estimate, made 4 weeks ago, was a safe one, and that instead of from 15,000 to 25,000 lbs., he will have from 25,000 to 30,000 one lb. combs; the finest he ever saw. He will make us his first shipment this week. We had a shipment of 8 cases of one lb. combs from J. A. Green, of Dayton, Ill., the first we have had. About 4,000 lbs. of orange blossom extracted honey from Alderman & Roberts, of Iowa, West Florida, and sold at 9c.

We quote our market prices, as follows: White clover, one lb. combs 20@22c; white clover, 2 lb. combs 18@20c; extracted from 9@10c.

BEESWAX—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatham Street.

CORRESPONDENCE

For the American Bee Journal.

The Naughty Hybrid.

JAMES HEDDON.

I will venture to say, had it not been for the sharp and business end of bees, there would have been more failures in our business than we can now boast of, which is no small number. Almost everybody would keep some bees, "just a few for their own use," were it not for their poisonous little javlins. This is an established and well-known law in human nature. This same law applies forcibly to the "naughty hybrid."

Had it not been for the fact that hybrids, crosses between the German and Italian bees, were far more irascible than either of the races from which they sprung, these bees would long ago have been the bee of present apiculture. Now it seems a little peculiar that a tolerably good-natured German bee, and a better-behaved Italian should produce offspring meaner than either race; but such is well known to have been a fact. I have told you several times before, that I had crosses between the brown German and leather-colored Italian, that were as well, or better behaved, and I think I may well say "better" than any other bees I have ever seen.

In this short article I wish to point out the reason for these two different conditions of affairs, and how I exchanged one for the other. I began my crossings as I have said before, from not only the best honey gathering strains of each race, but likewise the best behaved, viz.: the leather-colored Italians, and the larger brown, or gray variety of Germans. I took, and still take the ground, that the German bee is much better-natured than the Italians. The reverse of this has been supposed to be the case by bee-keepers who have used both, and from the quite reasonable reason that they have received more stings from handling German bees.

Now let us see if such results come about because the Germans have the meanest disposition. Bees seldom crawl on the hands to sting. We receive almost entirely all of our stings (except where bees are pinched, in which case all bees sting alike) from bees that take wing while being handled when opening hives, etc. Now one marked difference between Germans and Italians is that German bees fly into the air, and roll and tumble off the combs, falling into the air, and then taking wing very much more than do Italians. Considering the number they put into the air, we do not receive half as many stings from Germans as from Italians, though at the same time we may receive as many or more. Evidences of the innate mean disposition of the Italian bee are numerous. Their obstinacy in heeding the admonitions

of the smoker, on being driven from one point to another, when hiving or forcing swarms; their readiness to all tip up their abdomen and stick out their stings when the hive is opened during cool weather and many others.

Now, if this more irascible Italian bee is crossed with Germans, and the offspring inherit the mean, surly disposition of the Italians, at the same time the loose footed, and very ready tendency to take wing of the Germans, their product will be nearly as mean as Cyprians or Syrians are reported to be, and you have the old-fashioned "naughty hybrid." But on the other hand, if in our crossings we carefully foster that valuable propensity of the Italian of crawling about the combs, keeping themselves quiet and evenly distributed over them while being handled, in the point of gentleness you gain whatever your bees inherit of the really more amiable disposition of the Germans. Upon this plan I have worked, and in this way I have produced the strain of bees I now possess—one which surprises visitors and students when they see hybrids more gentle than any other bees they are used to handling.

Whenever any of the disposition to fly into the air or tumble off combs crops out among our stock, we make haste to weed it out, replacing it with the best in the apiary. All the above points are simple, and I think well known facts and deductions.

Dowagiac, Mich., July 26, 1883.

For the American Bee Journal.

Hunt Co., Texas, Convention.

Pursuant to a call published by the leading bee-keepers in Hunt County, Texas, a convention was held at Dr. Wm. R. Howard's residence, on the 19th day of July, 1883, for the purpose of effecting a permanent organization.

I. H. Hightower was called to the chair, and D. W. Yeager was chosen secretary *pro tem*.

The object of the convention was explained by the chairman, and a few timely remarks on the importance of thus associating ourselves together were made by several persons.

The convention went into permanent organization with the following named members:

Wm. R. Graham, Rev. C. A. Russell, Greenville; Rev. I. H. Hightower, Rev. D. W. Yeager, L. J. Green, J. E. Spoonemore, Wm. M. Matthews, Jasper McCullough, R. N. Guest, Rev. W. H. Fitz, J. W. Farmer, J. H. Maxwell, Wm. T. Hodges, Dr. Wm. R. Howard, Kingston; Wm. E. Lowry, White Rock; S. E. Smith, Leonard, Fannin County, Lady members: Mrs. W. R. Graham, Greenville; Mrs. S. E. Smith, Mrs. J. H. Manlove, Leonard; Mrs. Wm. R. Howard, Kingston.

The organization then proceeded to the election of officers with the following result:

William R. Graham, President, Greenville; I. H. Hightower, Vice-President, Kingston; William R.

Howard, Secretary, Kingston; D. W. Yeager, Treasurer, Kingston.

The constitution and by-laws of the State, with the necessary changes, were adopted.

The organization shall be known as the Hunt County (Texas) Bee-Keepers' Association, and shall hold its meetings semi-annually.

Several important subjects were discussed with interest to all present, and a general good time prevailed.

Dr. Howard exhibited all kinds of improved appliances used in modern bee-keeping, as well as fine Italian bees, which were remarkable for the gentle and quiet manner in which they moved about upon the combs, when handled without smoke or protection.

A general expression of thanks was tendered Mrs. Howard for her kind hospitality in entertaining her guests, and to the Doctor for his efforts to make the meeting pleasant.

The convention adjourned to meet on Thursday, Oct. 25, 1883.

WM. R. HOWARD, Sec.

For the American Bee Journal.

The Use of Broad Frames, etc.

W. Z. HUTCHINSON.

Please allow me to thank Mr. W. H. Harmer for his article on page 357. I now see that my article copied from the *Country Gentleman*, might give the impression that I advocated the use of broad frames for holding sections. Such is *not* the case, and, if obliged to use them, I should give up the production of comb honey. It was that very "Heddon section rack," or rather case, that converted me to a comb-honey man. "Eight sections in a broad frame," is an argument often used in favor of frames 17½ inches long, and at present it has weight, but it will "grow smaller by degrees and beautifully less." I have used broad frames "just a little," just enough to know what they will do. They will give the bees too much surplus room at once; they will allow the bees to finish the lower tier of sections first, and then "tramp" over them while filling the upper tier; they will bother the bee-keeper when trying to reverse the sections. Why, I can take the whole 28 sections from the Heddon case while somebody else is getting out the first section from a broad frame! Broad frames may hang on quite a while, but they are doomed. Separators ditto. When the Heddon case and sections 13¼ inches wide, filled with foundation, are used, separators are entirely useless.

Just a few words more in regard to the standard Langstroth frame. Webster defines the word standard as "that which is established by authority." If Mr. Langstroth is not authority upon this subject, who is? If he cannot change the standard, who can? We all know that standards can be changed. France changed her standard of weights and measures to the metric system; our school boards often change the stan-

dard of the text books, and Mr. Langstroth has changed his standard frame. It has been intimated that "somebody else" changed the size of the frame, and then Mr. Langstroth's sanction was "wrenched" from him. If my memory serves me right, when Mr. A. I. Root began making the Langstroth frame, he sent to Mr. Langstroth for a frame, and this frame was used as a pattern. Not much "wrenching" there. But it is immaterial as to what were the causes that induced Mr. Langstroth to make the change.

But the practical question in regard to this matter is, which is and will be in the majority? Where the $17\frac{3}{8}$ frames are already in the majority, and the largest manufactories, and the most of them, the editors of the principal bee papers, and Mr. Langstroth himself, have adopted this size, what else can we expect than that it will remain in the majority.

Rogersville, Mich.

For the American Bee Journal.

The Standard Langstroth Frame.

M. M. BALDRIDGE.

There is not a particle of "proof" in the two column editorial, on page 305 of the BEE JOURNAL, that the "standard" Langstroth frame—the only point at issue—is $17\frac{3}{8}$ inches long, outside measure, nor anything of value, when properly interpreted, to show why Mr. Langstroth should prefer a frame $\frac{1}{4}$ inch longer than the standard.

In the December BEE JOURNAL for 1878, page 427, appears an article from my pen showing that a mistake had been made by some in making the frame $17\frac{3}{8}$ instead of $17\frac{3}{4}$ inches long, outside measure, and calling it the standard Langstroth. Appended to that article are remarks, credited to Mr. Langstroth, which do not deny the correctness of my position, namely, that the standard Langstroth frame should be $17\frac{3}{8}$ inches long, outside measure, but simply that Mr. L., at that date, preferred a frame $\frac{1}{4}$ inch longer! But what Mr. L. preferred, at that time, was foreign to the point at issue, as was fully explained by me in an article on the same topic, on page 163, April BEE JOURNAL for 1879, to which the reader is referred for details. As Mr. L. has never responded to that article, I have a right to assume that he became satisfied that he did not fully understand my position when he replied, as is claimed, to my previous article.

Now, let me examine the "reasons (?) " credited to Mr. Langstroth, why he prefers a frame $\frac{1}{4}$ inch longer than the standard: "Considering the accuracy which may be obtained in making the frames stiff and perfectly square, I prefer the Root and Newman measurements."

Now, if any one can explain how the Langstroth frame can be made "stiff and perfectly square" with less trouble, or greater "accuracy," by making it simply $\frac{1}{4}$ inch longer than

the standard, he can do more than I or any one else whom I have talked with on this subject! If it be true that a longer and larger frame can be made stiffer and squarer, and with less difficulty, than a shorter and smaller one, and that, for such "reasons (?) " simply, we should adopt the longer and larger frame for the standard, then why not adopt the size and shape of the Langstroth frame preferred by Mr. Quinby? But this is also foreign to the subject—the text being, What are the correct dimensions of the standard Langstroth frame? and not what anybody "prefers," nor what shall we adopt as the standard.

On page 163, April BEE JOURNAL for 1879, the "Ed." appended some remarks to my reply to Mr. Langstroth, from which I now quote: "Many will vary the size of the frame from $\frac{1}{4}$ inch to 2 inches just to suit a notion, which should never be done. Nothing is more annoying than to have frames vary just enough to be useless for interchanging." I can endorse every word in that citation.

I am satisfied that the frame $17\frac{3}{8}$ inches long, now known to some as the "Root and Newman frame," was never made that length "to suit a notion," nor for any valid reasons whatever, nor for the purpose of obtaining any advantages over the standard Langstroth, but simply because it was copied after a blunder in the making of the standard frame, the blunder having first been made by old man Blunderer himself! The pretense that the length was changed from $17\frac{3}{8}$ to $17\frac{3}{4}$ inches so as to fit the one-pound section is sheer nonsense, as Mr. Root made the blundered frame several years before a one-pound box was even thought of—in fact, the blunder was made more than ten years ago!

Mr. Langstroth is credited with saying that "Mr. Baldrige is in error." But in what respect? In regard to the correct length of the standard Langstroth frame? By no means. But simply "in error" that $\frac{1}{4}$ inch in the length of the frame destroys its "interchangeableness." Now, is that true? As the inside length of the box that holds the $17\frac{3}{8}$ inch frames is $18\frac{1}{8}$ inches long (see page 331 of Mr. L.'s book), this would leave a space of only $\frac{1}{4}$ inch between the ends of the $17\frac{3}{8}$ inch frames and the box. Now, is that sufficient space for a good practical hive? It may be for some, but it won't do for me. And if the frame, as well as the hive, are each made $\frac{1}{4}$ inch too long, the projections of the top-piece will also be $\frac{1}{4}$ inch too long, and these must be cut off before such frames can be used in a box, properly made, to hold the $17\frac{3}{8}$ inch frames. So it will be seen that the proper "interchangeableness" of the frames is very disagreeable to say the least.

The 3d revised edition of Mr. Langstroth's book is dated March, 1859, over 24 years ago. But since that date there have been several editions published, and, I presume, one or more have been issued since

Mr. L. is credited with what appears on page 427 in December BEE JOURNAL for 1878. In the 3d revised edition, and in every edition of that revised edition that I have examined, full and explicit directions are given for making what has become known as the "standard" Langstroth frame and hive, and I am not aware that any change has been given therein by foot note, or otherwise, in the length of the frames from $17\frac{3}{8}$ to $17\frac{3}{4}$ inches, nor in the dimensions of the boards that enter into the construction of the box that holds the frames. It is true that the book is "stereotyped," but that is no excuse for not calling attention to the change in the length of the frame and the hive by foot note, or otherwise, if Mr. Langstroth thought such change was really to be desired. Now, when a writer of influence, like Mr. L., "prefers" a change, and especially one of so much importance as a change in the dimensions of a "standard" frame and hive for beekeepers, he should not only give at least one or more valid reasons, in case he attempts to give any, for making such a change, but he, or his publishers, should likewise give proper notice of such change in his only authorized work on bees, so that the purchasers of the book will not be misled by its teachings. Either this should be done or else the sale of the book should be discouraged by the advocates of the "blundered" frame, which, perhaps, should henceforth be designated as the Root and Newman "progressive" frame!

St. Charles, Ill.

["Mr. Baldrige is in error" in "presuming" that there have been "one or more" revised editions of Mr. Langstroth's book published since the item from him was printed in the BEE JOURNAL for 1878, page 427. No revision has been made since March, 1859. At our request Mr. Langstroth is preparing an article on this subject for the BEE JOURNAL, and one, we hope, that will forever settle this unprofitable controversy.—ED.]

For the American Bee Journal.

A Few Conundrums on Bees.

A. E. FOSTER.

Why is honey like liberty? Because eternal vigilance is the price thereof.

Why is the bee business like a poor man's purse? Because there is no money in it; or to suit everybody. Why is a well kept apiary like an old cheese? Because there are millions in it.

Why are bees, during the honey season, like clowns? Because they are pleasant and agreeable, doing their managers all the good they can.

Why are bees like merchants? Because they have stores and "cell" honey.

Why are bees seeking among flowers like young fellows going to see their

sweethearts? Because they are seeking their honeys.

Why are bees like the English nation? Because they are loyal to their Queen.

Why are bees like old toppers? Because they sometimes carry intoxicating beverages to their homes and drink themselves to death. (This thought is produced by the cider mill.)

Why is an occasional colony of bees like some government offices? Because they are filled with drones.

Why are bees like good sailors? Because they always know their latitude and longitude.

Why are bees like rich young swells who visit our watering places? Because they fly around all summer spending an active life, then loaf in winter.

Why do not bees believe in God? Because they obey not his laws; they murder, steal and break the Sabbath. Covington, Ky.

For the American Bee Journal.

Kindness to Bees.

W. H. SHIRLEY.

Kindness to bees produces kind bees to a great extent. When we had from 6 to 18 colonies, we could call them "little pets," "nice little bees," etc., and take an hour to do a little work with them, where, now, ten minutes must suffice. Then our bees were good-natured enough.

In breeding, especially, we were gentle in handling them at that time. In the fall of 1881, just before the surplus honey was removed from the hives, in our apiary, some one, for sport or mischief, tried one night to take a little honey, but the bees made it too hot for them, and they only succeeded in partly removing the sections, and left the hive so covered up that we did not notice it until the time came for removing the honey from all of the hives. I came to this hive, as to all others, and removed the cover, but I took "leg bail" for shelter. After they quieted down again, I approached more carefully, and succeeded in taking off the honey with but few stings.

Next year, 1882, we reared two queens from that colony, to see if that cross feeling was hereditary. It proved to be, in that case, as I know by the feelings of the past.

Now, our first point in breeding is to handle the breeding colonies carefully, especially when rearing queens, giving our first choice to the "bread and butter" colonies, regardless of color.

I had started out to show where my humble stand-point was, on the strain of bees that suited me, but I have just received the prescription for strained bees from Dr. E. B. Southwick, Mendon, Mich., and as he gives us permission to have it published, I will give place for the Doctor's letter, as he has done it up in much better shape; only adding first, that our fancy strain is about $\frac{3}{4}$ brown German and $\frac{1}{4}$ dark leather-colored Italian, as my experience leads me to

think that black bees have $\frac{3}{4}$ of the "bread and butter" qualities.

2. I select young queens to breed from that are from 1 to 2 years old, as a rule, with exceptions.

3. I do not like old combs to rear bees in, as I have seen combs old enough to dwarf the bees, that were hatched in them. If a good deal of age in combs will make smaller bees, will not a little help do the same thing?

4. Before God gave the honey bee the command to gather honey from flowers, perhaps they lived on manna, buckwheat flour, maize, etc. I guess now almost any bee will gather the honey if God will furnish the shower. I for one will take my chances on it.

Dr. Southwick's letter is as follows:

The Careful Breeding of Bees.

E. B. SOUTHWICK.

Concerning the different strains of bees—the coming bee, the yellow, the leather-colored, the blacks, or this man's peculiar kind, or that man's extra bred, I never have expressed an opinion. There are so many writing on that subject, that there appears to be scarcely room for one who is as contrary as I am in everything; but my ideas and opinions are always free when I have time to give them.

It is my opinion that men, animals and insects (the bee included), are just what they are, through the force of circumstances; that is, a family of man and its descendants can be brought to a high state of intelligence or size and strength, by circumstances, or they may be brought down to idiots or pignys by circumstances. So it is with everything that has life, either animal or vegetable.

The Italian bee, when brought to this country, had peculiarities that the blacks had not; they were more docile and easier handled, and some other things that they were noted for, and puffed very highly, and sold at high prices, and the breeders and dealers gave them every chance to improve in the very qualities they were noted for, and the purchaser gave them the same extra chance. For instance, all the visitors were taken to see the new bees—the hive slowly approached, the cover carefully removed, the nice little fellows exhibited and carefully shown, with their beautiful yellow rings and their mild disposition. But the blacks are approached in a hurry, the hive jerked open, the smoke puffed in, the frames jerked apart, and everything done in a rough manner, for they are nothing but cross blacks,—not thinking that that is just what makes them cross.

The same can be said of all other bees, that I have said of the Italians and blacks. I do not wish to be understood that the foreign bee has no qualities superior to the blacks. I think they have, and I think the blacks have qualities superior to the Italians. I think that if either kind are taken, and in every respect given the best chance, they will become the best bees. In proof of that I will cite a case: When the Holstein cattle

were first imported, a man bought a two-year-old heifer; his neighbor had a common one of the same age; they both came in at the same time. The neighbor thought he would see what he could do with his, so he fed his stock plentifully with the best milk-producing articles he could get, which so increased the power of their milk-secreting organs, that the third generation beat the Holstein in milk and price.

But, of the particular strain, different men have, some one color, some another, and each contending that his or her particular color is the best.

To explain all, I will give you my opinion of Mr. Heddon's strain. He bought some black bees that were large and great honey-gatherers. The question is, how came they such? My opinion is, that their race had, at some previous time, been located in a place where there was a continual flow of honey during the entire summer, and, as they had continual work to do, they acquired the habit of steady industry, and, as they were continually at work, their size, strength and ability to gather honey increased also, until they would outdo all others not under as favorable circumstances. Had they been light-yellow Italians, they would have been just as good and no better. His crossing with the Italians, I should care but little about.

Others having extra strains of bees may have those that have been improved by some peculiar circumstance, and are really better than the common bee.

Bees that have good qualities that are the result of long-continued usage, are worth more, as it takes as long to breed out a good quality, as it does to breed it in, and they will retain these good points as long as circumstances will permit.

You will perceive that in bees I have no respect to color or nationality; my bees are mostly Italians, but I have some blacks, and I would not wish to part with them, for I am a little more certain to find comb honey with them, and I can make a little better exhibit of nice white comb honey from them than the Italians.

Perhaps you would like to know what I think on the condition that will insure an improvement in any kind of bees. Well, I believe that a locality where there is an even and plentiful flow of honey from pussy willows in spring, until frost kills the goldenrod and hearts-ease in the fall, is the best. This, with even weather and light winds, I think, would insure improvement, without any crosses; and did I wish to buy bees and knew of such a locality, and of bees that had been bred in-and-in there, for the last 10 years, I would buy, with my eyes closed to color or pedigree.

You may ask if I think importation has done any good to the business? I will say that I think it has much, and the importers are worthy of much credit for what they have done. Did not the introduction of the Holstein heifer into that neighborhood improve the milking qualities of the cows there?

Mendon, Mich.

For the American Bee Journal.

To Michigan Bee-Keepers.

PROF. A. J. COOK.

We Michigan bee-keepers are unfortunate this year, as the Toronto meeting of the North American Association and our State Fair come at the same time. The American Association offers great inducements. It is the first meeting held in Canada, and everything will be done to make it a grand success. The hope and prospect of having our great and venerable Mr. Langstroth with us will give this occasion a rare prestige. I hear of delegates coming from Florida, Texas, and many from the States nearer by. Who will want to miss it?

Our State Agricultural Society have done everything we have asked to make our State exhibition a glory to us and to the State, so we have extra inducements to remain at home. Some, of course, must do the one, and some the other. Now I wish to appeal most earnestly for all to do the one or the other. I would ask with equal emphasis that our Michigan bee-keepers send to me quite accurate reports of the season's harvest, that I may carry up to Toronto a report that will do Michigan credit. The vice-president in each State should receive full reports from the various apiarists.

Let me then urge all bee-keepers in every State to pay most earnest heed to these two valuable points. See that your own State Fair is grand in its honey exhibit, and that your vice-president goes up to the North American meeting with a hat full of valuable statistics. In both these ways, apiculture will be greatly advanced.

Lansing, Mich., July 28, 1883.

For the American Bee Journal.

Size of Standard Langstroth Frame.

W. P. T.

I have been looking on at the controversy on this question, and being somewhat interested in it, I have not failed to form my own opinion on the matter. It is true that my first knowledge of bee-keeping was received from the perusal of "The Hive and Honey Bee," which you will, perhaps, say "is something akin to going back to the dark ages of the past."

There appears to be something definite and positive in the assertions and quotations of Messrs. Baldridge and Heddon, whereas there are doubtful and inaccurate statements on the other side; thus "the last edition of Mr. Langstroth's book (the fourth) was published about 25 years ago;" on reference, however, I find that the third edition was published in 1863.

In commencing I tried to make my hives from Mr. Langstroth's description, but in 1869, I sent to Messrs. Langstroth & Son for a pattern. This, when received, I found to be somewhat different from the hive described, the back and front were of $1\frac{1}{2}$ inch stuff, which admitted of

deeper rabbets for frame ends. Thin strips of hard wood were put in for the frames to rest on, and instead of the large triangular top-bar, a small piece was worked out of the top-bar for comb guide. In fact, it might be said to be "the improved Langstroth hive." But with all these changes the dimension of the hive $18\frac{1}{8}$ and the outside dimensions of the frame $17\frac{3}{8}$ were preserved. With this model I went to work and made hives and frames, and it was not until some years later, when I got a supply of frames from a dealer, which were made up and used without measuring, that I discovered that the bees would almost invariably stick these last named frames fast, and that they were $\frac{1}{4}$ inch larger than those received directly from Mr. Langstroth. I look upon it that the $4\frac{1}{4} \times 4\frac{1}{4}$ section had nothing to do with the maker, being of much more recent introduction, and again, the frame as sent out by its inventor, was only $16\frac{3}{8}$ inside (vide third edition, page 372).

I have now a lot of the $17\frac{3}{8}$ frames on hand, which I will not make up, finding that it does as stated by Mr. Baldridge, "destroy the interchangeableness," and if any one doubts it, let him try to use a $17\frac{3}{8}$ inch frame in $18\frac{1}{8}$ inch hive, for I do not see that it has been asserted that Mr. Langstroth has sanctioned a change in the size of the hive.

Ontario, Canada, June 25, 1883.

[The only thing worth commenting upon in the above communication, is the mistake made by W. P. T. about the third edition of Mr. Langstroth's book being published in 1863. If he will take the trouble to look at page viii. of the "Preface," he will see that Mr. Langstroth's Preface to his last edition is dated "March 1859!" The date on the title page is the date when a fresh supply was printed from the old plates. It is therefore not an "inaccurate statement" to say that "the last edition of Mr. Langstroth's book (the fourth) was published about 25 years ago"—the full 25 years being up next March.—Ed.]

For the American Bee Journal.

Side Storing Sections a Failure.

J. CRAYCRAFT.

The controversy between Dr. Southwick and Mr. Demaree is very interesting, and each can and will be sustained by the voices of many bee-keepers. I take sides with the shallow frame for this latitude, but not so long as the standard Langstroth; greatly preferring a frame of the same depth, $9\frac{1}{2} \times 13\frac{1}{2}$, as being far better for the production of comb honey and building up, in the spring; the space being more compact, requiring a less number of bees to keep a given space the proper degree of temperature, at a time when all the working bees are needed in the fields; and for success-

ful and economical queen-rearing, it is far ahead of the standard Langstroth. I think the Doctor's digression, on page 369, fits the experience of many bee-keepers that use the broad section frame. I have tried both to my sorrow and loss, this season, here in the apiary of Dr. Allen. I find it almost impossible to get bees to work above in a 10-frame Langstroth hive, until you have sections drawn out in the broad frame below, on either side of the brood, first removing three frames, and then you will find pollen, and sometime eggs and brood, in them, when you remove them above, and by the time you have had all this work done, and the three frames replaced, and the bees at work, you will have lost the best part of the season (at least here, where clover is our crop). I do not think I could ever make a success in the production of comb honey, in the broad hanging frames for sections. I have removed all of them from my hives, and will pile them up as relics of the dark ages, in bee-keeping.

I hope many of the readers of the BEE JOURNAL will take the advantages offered on page 366, to attend the Kentucky State Bee-Keepers' Convention to be held at the Exposition building in Louisville, Ky., Aug. 29 and 30, and also avail themselves of the opportunity of exhibiting their bees there. This will be a grand opportunity for queen breeders to show their stock. The secretary, Dr. N. P. Allen, Smith's Grove, Ky., extends a cordial invitation to all bee-keepers to come and be with us, and help to make this a grand show of our little industrious friends.

The honey season is about over here, with the exception of some of our finest colonies, that are still building comb and storing honey in sections from the red clover, of which there is an abundance here. I wish our bees were only all "red clover bees;" they are "the coming bee."

Smith's Grove, Ky., July 30, 1883.

For the American Bee Journal.

Changing a Standard.

S. GOODRICH.

The question of a standard frame has been agitated through the columns of the BEE JOURNAL for sometime, and each advocate of a standard frame would, no doubt, be very glad to have the fraternity adopt a standard frame, provided it should be his particular "pet frame," but how many would be willing to make a change. Take the class of men who have several hundred colonies, or even 50 colonies, it would be attended with considerable expense; then if the "standard" should happen to be a larger or longer frame than the one they were using, the real expense would be greater than to the party that is now using a larger or longer frame than what would be decided as a standard. In the former case the lumber in the hives might be a total loss, where, in the latter, much of it could be worked over.

I imagine there are but few of us who would feel that we could stand the expense and trouble of changing, and should a standard be adopted just after a poor honey season, then to have this expense stare us in the face, I doubt whether there are many of us that would be zealous enough in the cause to make any change, but let us look at the other side of the picture. Apiculture is but in its infancy in this country. Every practical apiarist can see at a glance the advantages to be derived from the use of a standard frame, both to themselves and the fraternity in general, to manufactories, supply dealers, and all who want a dollar's worth of fixtures.

I would suggest that this matter be brought up before the convention at Chicago, this fall. Let there be a committee appointed to hear the arguments in favor of each frame, by its friends, and select one as a standard. Let this decision be final. Let every member of the society work for this frame to bring it into general use.

It is natural for every man to think he has the best frame, and has his reasons for thinking thusly. Let such put in an appearance at the convention in Chicago, this fall, and satisfy this committee that he has the best frame, all points taken into consideration, and he will, undoubtedly, have the honor of introducing the "standard frame of America."

I, for one, hope that some of the leading apiarists of the country will take up and push this matter of a "standard frame" to a final settlement, and do it before the country is filled with all sizes and descriptions of frames.

Urbana, Ill.

For the American Bee Journal.

Theory Reviewed by Practice.

G. M. ALVES.

Dr. E. B. Southwick gives us an article on "the best size of frame." At the outset the Doctor tells us that he prefers theory to experience, and in justice to him we must admit that he maintains his preference throughout.

Indeed, it matters not with the Doctor that statistics show that bees winter as well in the Langstroth hive as in others.

It matters not that statistics show that there are more Langstroth hives in use than all other hives combined.

It matters not that the great majority of our hive makers turn out almost exclusively the Langstroth hive.

It matters not that there are scarcely over two or three hive makers in the West who make a square frame hive.

It matters not that the Doctor is told that the queen enters the sections only when she is blocked below, and that experience shows the Langstroth to be as free of this trouble as other hives.

It matters not what statistics are offered. The Doctor's *theory* "hath

a stomach for them all." His *theory* shatters the statistics and annihilates the facts in a twinkling.

Many of us have been wont to admire the slow and steady accumulation of the world's knowledge; and to gaze with interest upon facts gotten by toil, as they go to help make up the world's progress. A progress rising slowly but surely upon the indestructible basis of facts—but in the presence of the Doctor, I suppose we should do so no more.

When I first glanced over the Doctor's article, some old lines ran in my head, and as they are quite *apropos* to the Doctor's very peculiar ideas, I know I will be pardoned for quoting them.

Philosopher.—"Dost thou know the thing of theory?"

Herdsmen.—"Nay, good sir, I know not the word, but this truly I do know—I saw it with my own eyes."

Philos.—"Out, common fellow! canst thou persuade the learned by thy vulgar seeing?"

Henderson, Ky., July 25, 1883.

For the American Bee Journal.

Pollen, Breeding in Winter, etc.

A. R. KOHNKE.

When I wrote to Mr. Heddon my observations on this subject, I was under the impression that he still held that bacteria in honey or pollen caused dysentery, which theory I could not bring into harmony with observed facts. Mr. Heddon and myself have discussed this subject personally quite often; in some points we agree, and in others we do not. As Mr. Heddon quotes only part of my letter, I will take the liberty to add the remainder of my conclusion, to which I have come by observed facts, not by already finished experiments, hence can be called a theory only.

For a simile I will draw on the one given by Dr. A. B. Mason, as quoted by Mr. Heddon. A man is hung until he is dead. A bee eats pollen until it is dead. Is there a man alive who will ask no questions after having observed the man's hanging and dying, or the bee's eating and dying? Man wants to know the whys and wherefores which constitute the largest part of the progress in science, as well as everything else. And now for the first question after having seen the dead man or bee. Nobody would ask, why did the man die, or why did the bee die; but why was the man hung, and *why did the bee eat pollen?*

These are pertinent questions, and the ones the answer to which will enhance our knowledge on the subject. An answer to the first question would be, the man committed murder, and with reference to bees, they had nothing else to eat, just where they had clustered.

To be wholly informed with reference to the dead man, we would, perhaps, ask many more questions, such as, why did he commit the murder; he may have done it out of revenge, or to rob, or to hide a crime, by killing

the witness, etc. To prevent his hanging, it would not be practicable to confiscate the ropes, nor would it be practicable for an extensive apiarist to confiscate the pollen. That may be done with a few colonies, but when the number runs up to a hundred or more it will be found to be a little too much of a job to examine all the frames and take away those containing pollen, with, perhaps, a large part of the honey. I am convinced that bees will not eat pollen if they have hydro-carbon sweets in the form of honey or sugar candy.

Another reason for this untimely consumption of pollen, is breeding, which is caused by their being housed or covered too warm. A translated article from a German paper seems to point in that direction; if bees have plenty of honey or candy they do not freeze to death so easily as some are inclined to believe they do, and I think, by what I have seen, that this housing and packing business is largely overdone. They do not pack bees in Sweden or Russia; not much, but leave them enough honey to last them from 6 to 8 months. Hence, dysentery is chargeable not to the presence of pollen, but to the absence of proper food, or such other causes as will induce the bees to untimely breeding, of which I have named one, viz.: packing or housing too warm. Still there are other causes having the same effect; for instance, frequent disturbance. Also too much open, or poor honey may cause the same disease. In each case the apiarist should strive to avoid the remotest cause, not the direct; that being the safest way to act.

I intended to make some more experiments next winter before touching this subject in a paper, but since Mr. Heddon cited my observations to substantiate his theory, I thought best to give all I think I know about it, and have the bee-keeping fraternity combine in making further experiments and observations.

Youngstown, Ohio, July, 1883.

For the American Bee Journal.

Winter and Summer Frame.

J. E. VAN ETEN.

I have been very much interested in the discussion carried on in the BEE JOURNAL as to which is the best frame, the shallow or the square frame. The subject has been very ably handled, and the comparative merits and demerits of each very clearly pointed out. Two points, I think, have been established:

1. That the shallow frames are best in summer, because from them the bees more readily enter the sections above.

2. That the square frames are best in winter, because they better enable the bees to cluster in a spherical form and retain their heat.

Granting both these propositions to be sound, then why could not a frame be made to answer both purposes by changing its position? Take, for instance, a Quinby standing frame

which is about 9x17. In its usual position it is a shallow frame, and as such well adapted to summer use; placed on its end it would give every advantage of the square frame for winter use, and I find, upon trial, that the same case will cover the frames in these different positions. Will not some of the abler writers for the BEE JOURNAL express their views upon this point?

Kingston, N. Y., July 27, 1883.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Getting Pollen Out of Frames.

Is there any way of getting the pollen out of the combs?

Whitby, Ont.

IRA ORVIS.

ANSWER.—So far as I know, no practical method of getting pollen out of combs, has yet been discovered.

Ripening Honey, etc.

Please answer the following through the BEE JOURNAL:

1. Intending to buy several colonies of bees of a neighbor, $\frac{1}{2}$ mile distant, how shall I move them to my place, at this season, without losing any?

2. Can extracted basswood honey, which is a little green, be kept from souring in a barrel, and if so, how?

3. How shall I clip queens' wings? I find it a difficult task to clip them with scissors.

W. FISHER.

Hamler, Ohio.

ANSWERS.—1. Twice I have moved my whole apiary about 10 to 15 rods, and once $\frac{3}{4}$ of a mile. Select a cool, rainy day, when bees are not flying. Close up the hive and give them thorough ventilation above. I give the whole top of the hive a covering with wire cloth or mosquito bar, and, if the bees are any way strong, I place the mosquito bar over a rim, over this open top, several inches in height. Smoke the bees thoroughly—move them to the new stand, and let them set a few hours, and, if the weather is cool, say 10 to 20 hours, until they quiet down, sprinkling them several times with water during that time. Let them out to fly just at sun down. Smoke, and rap upon the hive before you open it. Place a small board up in front of the entrance of each hive, so that each bee must come out cautiously or bump its nose, which will cause it to mark its new location. No other bees should be left in the yard from which you make your removal, and the old yard should be cleared and cleaned up from anything in the line

of bee fixtures, and made to look as different as possible. If a few should return, they will cluster somewhere about the old location, and can be easily brought back. If there are colonies left after you take yours away, I would advise you not to move them until winter.

2. I have never extracted honey so thin as to have it sour. Thin honey should be kept in one gallon crocks, having their tops exposed to the air. I am not sure that I know of anything just exactly adapted to your case, but perhaps a little salicylic acid dissolved in the smallest amount of hot water possible to dissolve it, and stirred into the honey, would prevent souring.

3. After stating that I am opposed to clipping queens' wings for any purpose whatever, I will say that the best method I know of is to tangle them up in a small mosquito bar sack, or any sack made of similar material, the meshes of which are just small enough to prevent the queen passing through. As soon as she becomes tangled up her wings will stick through the meshes. Any sharp scissors are the best thing to clip them with.

SELECTIONS FROM OUR LETTER BOX

State Convention for Iowa.

Bees have done well here this season. White clover is now over, and we have a good crop of white honey. I would like to say a few words to the Iowa bee-keepers in regard to calling a State convention on or about the time of the State Fair at Des Moines. The Iowa State Agricultural Society offer \$106.50 in premiums to the bee-keepers of Iowa. Now let us have a State convention organized this fall. What say you, Iowa bee-keepers, speak out and let us know what you all think about it through the BEE JOURNAL.

D. S. BURBANK.

Grundy Centre, Iowa, July 30, 1883.

Good Honey Crop and Increase.

Since I have adopted the chaff-packing in winter, I have never lost a colony, and I have no trouble with the moth, nor with disease that some speak of. Neither have I had any spring dwindling, to amount to any thing. Last year I had 140 colonies, from which I obtained about 8,000 pounds of nice honey; a large proportion of which I extracted. I sold it all, readily, at 15 cents per pound. This year I have realized from my 140 colonies, about 350 swarms, which I have doubled up to about 160, which now makes about 350 colonies of bees in good condition. My doubling up process, I find, works well, for with

two or three swarms to a hive, I could tier up, with section cases, three or four high, and as a result, I have on many of my new colonies from 48 to 96 pounds of beautiful white clover honey; and up to this date I shall receive about 7,000 or 8,000 pounds, of as nice honey as ever went into the market, for which I shall realize, probably, from 10 to 15 cents per pound, and if there comes a fall supply of honey, I shall realize about as much more. But we are in a honey drouth now, and there is no telling how long it will continue.

WM. A. DUSTEN.

Bees in Texas.

My bees are doing well. I extracted last week, and found my bees rich for the time. On examination, to-day, I find that I can take another 1,000 pounds of honey in ten days. The strange part of this story is, that my neighbors, with black bees, get no honey. One man with 30 colonies of black bees, living a mile distant, has no honey, and he did not have a swarm this spring; and for miles around, there has not been a swarm among the native black bees; every one complaining of a bad year for bees. I had 20 colonies in the spring, and had 20 swarms. My bees are all pure Italians, bred for their honey-gathering qualities. I think the above comparison is good evidence in favor of Italian bees, in Texas. I believe that my method of managing bees will, in time, to a certain extent, improve them, as the winters here are so mild, no bees would die from cold, only by starvation; so, in the fall, I dispense with colonies that did not prove valuable during the honey season, by killing the queens and uniting the bees with others and saving the combs for swarms, the next spring. Thanks to you for the article on "Sweet clover for the South," in the BEE JOURNAL last year. Your suggestion caused me to give it a trial. It is not old enough to bloom yet, but I see that it is a success without a doubt. I shall plant several acres of it this fall.

DR. J. R. REEVE.

Martinsburgh, Texas, July 21, 1883.

Bee Pasturage.

1. Would it not be an excellent plan to turn a drove of pigs into the clover pasture, letting them subsist wholly on sweet clover until July, after which it can grow for the bees to utilize?

2. Would it be well to mix seven-top turnip seed with tuckwheat before sowing for the bees?

F. M. CHENEY.

[1. It would.

2. Yes, for the "turnip seed" would come up in the fall, and in the following spring yield nice bloom for the bees. They get both honey and pollen from it.—Ed.)

Honey is of the Best Quality.

This has been the best year for honey I have ever seen, and the honey is of best quality.

G. A. DE LOÑO.

Key West, Fla., July 20, 1883.

Honey Crop in Mississippi.

Since my last report we have had an unusual amount of rain, which has been quite a drawback to the bee-keeper. There was one advantage therefrom, viz.: the white clover continued to bloom, and every day that the bees could work was taken advantage of by them. Now we have the swamp woodbine (cow-itch) in full bloom; also the button or elbow bush (*cephalanthus occidentalis*), and last not least, the Indian corn yields a most delicious honey. All that is needed now is sunshine. I have now taken off over 11,000 pounds.

O. M. BLANTON.

Greenville, Miss.

How to Keep Fire in a Smoker.

I have been plagued for some years with an 1½ inch smoker. I have had a great deal of difficulty in making it burn and hold a fire. I think I have overcome the trouble, the knowledge of which may be of use to others using a small bellows. I made a solution of saltpetre, mixing a heaping tablespoonful of saltpetre with about a pint of water. In this I saturate the rags or wrapping paper, and when dried, I find that they burn entirely up, giving a strong and prolonged smoke. It might be, that by using a stronger solution of saltpetre, porous or half-decayed oakwood could be used to advantage, but I have not tried it yet. THOS. P. BONFIELD.

Kankakee, Ill., July 30, 1883.

Stock Peas for Honey.

For the benefit of bee-keepers who live in the sourwood country of Tennessee, and where there is a gap between sourwood and other honey yielding blossoms (such as heart's-ease and rough sumac), I will say that stock peas, the whip-poor-will variety, will just fill the gap, if planted on May 15, and they will continue to yield honey for 2 months. The bees worked on peas, last year, from daylight till dark. I saw them working on peas until it was so dark that I had to stoop down very low to see them. It is just 2 months from the time of planting till they blossom.

J. A. P. FANCHER.

Fancher's Mills, Tenn., July 27, 1883.

Industry of Bee-Keepers.

Be up early in the morning; be up late at night; be here; be there; be on the watch. "Eternal vigilance" some one gave as the watch word of bee-keeping, and a truer one never was given.

"No manual labor about bee-keeping," some man remarked the other day, "Well, I would like to have one of those easy laborers start in with me in the morning, and I will guarantee that the pillow will feel good to his head at night, hiving from 10 to 18 swarms per day."

To keep up with a heavy honey flow, with other work, will keep one good able-bodied man on the jump 15 hours out of the 24. And now, what is the outlook for pay for all this work? The question with me is, How

cheap can I produce honey to sell, and keep my family. If we only had a strain of bees that could raise potatoes, wheat, corn, sugar, wool, etc., etc., then we would be independent. I think honey will come down to bed-rock prices before long. If it does not, let us bee-keepers, who are in the business now, try and get every person we can to embark in this great non-laboring money-making pursuit. Mr. Bingham once said to me: "A bee-keeper wants to live two lives; one to learn the business, and one to learn to make anything in the way of this world's goods," and I think he had it about right. W. H. SHIRLEY.

Glenwood, Mich., July 19, 1883.

A "Boss Colony."

I have one colony from which I have extracted 143 pounds of white clover honey, and I expect to get enough more to make it 175 pounds or more, before buckwheat blooms. We have no basswood here, of any account. G. H. KNICKERBOCKER.

Pine Plains, N. Y., July 25, 1883.

Strained vs. Extracted Honey.

Bee-keepers in this section are very despondent; the honey crop is not more than a third of what it should have been. One of my neighbors, who has 600 colonies in three apiaries, has taken only 12,000 pounds of extracted honey; at the commencement of the season he was confident of taking 140,000 pounds; but as it is almost time to stop extracting, he will not obtain much more. From 185 colonies I have taken 9,600 pounds instead of 30,000 pounds as I expected. Please inform me, by means of the BEE JOURNAL, the difference between strained and extracted honey. Our honey is always classed as strained honey; as it does not sell for as much as extracted, we are inclined to object. I hope we have had the last article on the standard frame; to me it is very dry and uninteresting reading, and as they will never agree, I cannot see much use in arguing the matter any longer. M. T. HEWES.

New Rhodes, La., July 30, 1883.

[Extracted honey is obtained by the frames being uncapped and placed into a basket or frame holder, which being attached to a single rod is placed into a large can and revolved—the centrifugal force throwing out the honey from the combs, which runs down the sides of the can and is drawn off and placed in jars or some other desirable receptacle. Extracted honey is the *pure liquid*—minus the comb.

"Strained honey" is another thing—the result of hanging up combs, used in the breeding apartment of the hive, and pieces of comb containing bee-bread, dead bees, etc., and catching what passes through the cloth—that is strained honey, and is quite different from the pure virgin

honey, extracted as before described, still having the flavor of the bloom from which it came.

The strained honey known to commerce, is the adulterated—that which will not granulate. Consumers help to impose upon themselves by the false idea that pure honey will not granulate. They desire ungranulated honey, and dealers will attempt to supply the demand. Almost all pure honey will granulate when exposed for some time to light and cold. The granulated state is one evidence of purity. Much of the jar honey heretofore sold in the markets, and recommended not to granulate, is a very inferior article, composed largely of glucose.—ED.]

About Drones.

I have reason to believe that many bee-keepers allow the accumulation of too many useless drones, thereby lessening the paying qualities of an apiary. I have been in yards that seemed to be alive with the hum of big, fat, lazy drones, whereas we may as well have had those eggs deposited in worker cells. When I look at a drone, I think it takes a good deal of honey to keep it, and that honey comes out of my pocket. Permit just as little drone comb in the apiary as possible, and use the knife to cut off the heads of drones when capped over. Only a few drones, from choice queens, are necessary, and these are all that it pays to keep. In going through your bees, watch (as a hawk does a chicken) for the signs of the moth worm, and when found follow these signs at the point of the knife, and when the destructive enemy is found, exterminate without mercy.

A. E. FOSTER.

Covington, Ky., July 30, 1883.

Working on Basswood.

It is rainy, cold and wet here still, but between the showers and when it is warm enough, the bees work at a tremendous rate on the basswood, which is now on its "last legs." Some of my colonies have completed 30 two-pound sections from that source, during the past 10 days, while others have 40 combs nearly sealed, for extracting. Basswood beats the world for honey. G. M. DOOLITTLE.

Borodino, N. Y., July 30, 1883.

The Usual Dearth of Honey Now.

Bees are doing nothing here now, but it is the usual slack between basswood and sumac, and the late flow, which usually begins about Aug. 10 or 15. The prospects look favorable for a good yield of late honey. My bees increased from 18 to 33, and I have taken about 600 pounds of early honey, and about 30 pounds of comb. There are no practical bee men here in my neighborhood; all get comb honey in box hives, and consequently have no surplus yet. L. G. TRAVIS.

Oregon, Mo., July 30, 1883.

A Beginner's Experience.

In May, 1882, I bought 2 colonies of bees; one Italian and one brown. Last year my Italian colony increased to 5. I wintered them all safely. My brown colony increased to 3 by natural swarming, and they wintered all right. I wintered the 5 in a tight house, built for the purpose, and the 3 were wintered on the summer stands, by placing them in a tight store-box, a little larger than each hive; the front of the box I left partly open, so that they could fly whenever they desired. When spring came they were strong and ready for business, and so were my yellow bees, except one colony that swarmed on Aug. 5. They were very weak, though I had fed them all winter, whenever the weather would admit, but they soon recruited up and gave 2 as good swarms as I ever had. My 5 Italian colonies have now increased to 24, in good condition, and my brown bees have increased from 3 to 11, making 35 in all, from 2 colonies, since a year from last May, when I got about 49 pounds of comb honey; this year I have taken 150 pounds of comb honey. Up to the 1st of this month I did not extract any, as I had no extractor. I had one Italian swarm go to the woods, and 3 others that I hived lost their queens and went back to the old stand and remained.

R. A. ROSSER.

Nelsonville, Ohio, July 29, 1883.

Texas Honey Crop a Failure.

The Texas honey crop for this year may be set down now as a failure. The bees may gather enough to keep them in "rations" till the end of the summer, but I doubt whether they will get sufficient to winter on. I have already began to feed to stimulate them to make decent colonies for autumn, and I expect to keep on, more or less, till they get their full winter supply. We can expect no more honey of any importance this year. The leading bee man of this neighborhood has already fed some 600 pounds of old honey to his bees, some 36 colonies, and reports of feeding are heard all around. This is my first year as a bee-keeper, and it is a tough initiation into the mysteries of the craft. But *nil desperandum*, and better luck next time.

R. J. KENDALL.

Austin, Texas, July 27, 1883.

Cyprian Bees Ahead.

I have done well this summer. I started in the spring with 29 colonies, in good condition. They were wintered without loss. We now have 56 colonies. This country is "flowing with milk and honey," on account of the immense yield of clover pasture, both for cows and bees. The wet weather is now bringing on the second crop of clover. I still like the Cyprian bees best, and believe they are "the coming bee." My Cyprians are at work before the Italians, and are working on red clover to-day.

D. R. ROSEBROUGH.

Casey, Ill., July 26, 1883.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00, or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Do not send coins in a letter. It is dangerous and increases the postage unnecessarily. Always send postage stamps, for fractions of a dollar, and, if you can get them—one-cent stamps; if not, any denomination of postage stamps will do.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper, shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter, on your label, notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a statement of account every week.

May we ask you, dear reader, to speak a good word for the BEE JOURNAL to neighbors who keep bees, and send on *at least one new* subscription with your own? Our premium, "Bees and Honey," in cloth, for one *new* subscriber to the Weekly, or two for the Monthly, besides your own subscription to either edition, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

Bingham Smoker Corner.

Large Smokers need wide shields. Bingham's have them, and springs that do not rust and break, and bellows that sparks and smoke do not enter. The Conqueror has all improvements made to date, and a 3x7 inch stove, and 5x7 inch bellows. Sent post-paid for \$1.75. Address,

BINGHAM & HETHERINGTON,
Aubonia Mich.

The Very Best.

The Bingham "Conqueror" smoker is the very best thing I have tried in that line. M. M. LINDSAY.
Fulton, Tenn., July 24, 1883.

All Excelling. — Messrs. Bingham & Hetherington, Dear Sirs:—I am now selling your Smokers almost exclusively. You are excelling yourselves in smokers all the time.

Respectfully, J. G. TAYLOR.
Austin, Texas, May 10, 1883.

Cyprians Conquered.

All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am "boss." Bingham's "Conqueror Smoker" did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham.

G. M. DOOLITTLE.
Borodino, N. Y., Aug. 15, 1882.

During the following three months, Bingham Smokers will be sent post-paid, per mail, on receipt of the following prices:

The "Doctor" (wide shield) — 3½ in. fire tube,	\$2.00
The Conqueror (wide shield) — 3 in. fire tube,	1.75
Large (wide shield) — 2½ in. fire tube,	1.50
Extra (wide shield) — 2 in. fire tube,	1.25
Plain (bar. shield) — 2 in. fire tube,	1.00
Little Wonder (bar. shield) — 1¾ in. fire tube,	.85
Bingham & Hetherington Uncapping Knife,	1.15

With thanks for letters of encouragement, and the absence of complaining ones, we tender to our thirty-five thousand patrons our best wishes.

Very Respectfully Yours,

BINGHAM & HETHERINGTON.
Aubonia, Mich., June 1, 1883.

Special Notice.—We will, hereafter, supply the Weekly BEE JOURNAL for one year, and the seventh edition of Prof. Cook's Manual of the Apiary, bound in fine cloth, for \$2.75, or the Monthly Bee Journal, and the Manual in cloth for \$1.75. As this offer will soon be withdrawn, those who desire it should send for the book at once.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Sample Copies of the AMERICAN BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

The new two cent rate of postage for letters goes into effect on October 1. Three cent postage stamps will then be but little used. For all fractions of a dollar sent to us hereafter we should prefer either one-cent, or else five or ten-cent postage stamps. Do not send coins in any letter.

Do not let your numbers of the BEE JOURNAL for 1883 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

Mrs. J. F. Upton gives the following notice of this book in the Bath, Maine, *Sentinel*:

A guide to the management of the apiary for profit and pleasure, by Thomas G. Newman. This work is designed to initiate beginners in bee-keeping in all the secrets of successful bee-culture. Beginning with the different races of bees, the author takes his readers along step by step, carefully explaining the different kinds of bees, illustrating each kind with the eggs and brood, explaining the terms used, the production of wax and comb, and the work done by these wonderful insects. The establishment of an apiary is next considered; the best location, time to commence, how many colonies to begin with, what kind of bees to get, how to care for a first colony, keeping bees on shares, changing the location, all of which it is indispensable for a beginner to know. It is also important to know which kind of hive is the best, how to procure the best comb honey, how to procure it for market, how it should be marketed, what to do with candied comb honey, and how to extract honey. The scientific management of an apiary is then entered into, and illustrations of all the necessary appliances introduced. There is a chapter devoted to the honey extractor and its use, and another to comb foundation and its use. The various honey-producing plants and trees are named and illustrated. Various methods for exhibiting bees and honey at county and state fairs are described. The best and safest plans for wintering bees are discussed, the book closing with some general advice to beginners. The author says of his book on Bees and Honey, "it was not designed to supersede or supplant any of the valuable works on apiculture already published, but to supply a want for a cheap work for the beginners." We most cordially recommend this work not only to beginners, who will find it invaluable, but to all who are not already familiar with the lives and movements of these industrious and intelligent little workers. The information to be gained as to their habits, manner of breeding, intelligence, energy and wonderful instincts, by reading this book alone, is enough to make one regard the bee with admiration and amazement.

PRICE—Bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

A Few Seasonable Hints.

The usual dearth of honey in August set in a few days earlier than usual, and caused a stoppage of the honey flow in many localities—strong colonies have been gathering barely enough to supply the daily wants—and others have been living on their stores already collected. Sweet clover, catnip, mustard, etc., have been in bloom, but only yield sparingly of honey as yet—the weather has been too cool to allow the nectar to be abundant in them. In some cases, through carelessness in opening hives, robbing has been induced. In other localities but little cessation has been observed in the honey flow. Mr. Dougherty thus describes the matter in the *Indiana Farmer*:

It is encouraging to know that we have escaped the drouth which usually occurs during the latter part of July and first of August, while, of course, the bees ceased to gather a surplus, they have secured sufficient to keep them breeding right along. This enables the weak colonies to grow in fine condition, and putting the small after-swarms in fair condition to take advantage of the fall flow of honey, which, in most localities, promises to be exceptionally good, while in others insures a good supply of winter stores.

Weak colonies or nuclei can be built up very fast now. If you have empty comb or foundation to give them, they will build up rapidly on a moderate yield. Good colonies can spare a frame of brood and honey every few days, which, if given to nuclei, will build them up very fast. And just now is the time to begin to prepare for winter. See that all colonies have good laying queens, and that the queen has room to lay. If you have more colonies than you want double up the weak ones, making one good one, selecting, of course, the

fullest and best frames, for the one hive.

The honey market is developing—and there is some call for honey, but it is too early yet for a very extended sale. We hope that bee men will see to it that the local markets are well worked up, and then there will be no fear of overstocking the large markets, and thus running the prices down.

A bee-keeper, who called at our office last week, reported having worked up a nice trade in a city near by, and he confidently expected to sell not only his own crop in that way, but also the crops of all his neighboring bee-keepers. The pamphlets on "Honey as Food," that he had distributed to those he interviewed, had made much inquiry and consequent sale of honey. That is the way to do it—work up the local trade, and see that the surrounding towns are fully supplied.

Mr. W. Chitty, organist at Pewsey, Wiltshire, England, has sent us a copy of his newly-arranged music for the "Te Deum Landamus." It is partly founded on an air from Mendelssohn, and chiefly composed by Mr. Chitty, who will send it by mail for 12 cents, to any address. It is an excellent piece of music.

The new two-cent postage stamp is to be of a metallic red color, with a vignette of Washington. It will supersede the present three-cent stamp on the 1st of October.

The pamphlet "Honey, as Food and Medicine" is an excellent thing to give away at Fairs, where a good exhibit is made. A thousand copies will sell almost a fabulous quantity of honey, if judiciously given—say given to every one who buys a package of honey. Try it.

Articles for publication must be written on a separate piece of paper from items of business.

Trial Trip—25 Cents.

As the season for Fairs has arrived, and wishing to be able to reach several thousands of the old-fashioned bee-men, and by the aid of the BEE JOURNAL to lift them up to higher ground, adopting newer methods and progressive ideas, we make the following very liberal offer: We will send the Weekly BEE JOURNAL *three months on trial, for 25 cents*. In order to pay for getting up Clubs, we will give a copy of Fisher's Grain Tables, or Scribner's Lumber and Log Book, to any one who will send us five trial subscriptions (with \$1.25); for a club of ten we will give a cloth copy of Bees and Honey; for a club of 15, a cloth copy of the 7th edition of Cook's Manual of the Apiary; for a club of 25, we will present both the Manual and Bees and Honey. If any one wants these Books for nothing, here is an excellent opportunity to get them for a little exertion.

It is unwise to rush the honey into the market as soon as it is gathered, for it will cause a temporary glut in the market, and run the prices down. As soon as the fruit season is over, it will sell more readily.

Speaking of the usual August dearth in honey, an exchange remarks as follows:

There is, during August, a notable scarcity of honey flowers. This dearth commences sometimes in July. When this absence of bloom occurs, the bees are idle, and with this comes a consequent indolence of the queen.

It is desirable to provide artificial pasturage. By proper planting, we may have nectar-secreting bloom all the season, and there will be no need of supplemental feeding. The Syrian bees seem to breed on all the same, whether there are flowers or not. It is probable that in the desert regions of Syria, natural selection has produced this race, well fortified against those famous famines which, of old, sent the patriarch to Egypt for bread and corn.

Local Convention Directory.

1883. *Time and Place of Meeting.*

Aug. 14.	Cortland, N. Y. Union, at Cortland, N. Y.	M. C. Bean, Sec.
Aug. 29.	S. W. Iowa, at Red Oak, Iowa.	R. C. Alkin, Sec.
Aug. 29.	Iowa Central, at Winterset Fair Grounds.	Z. G. Cooley, Sec. <i>Pro tem.</i>
Aug. 29, 30.	Ky. State, at Louisville, Ky.	Dr. N. P. Allen, Sec., Smith's Grove, Ky.
Sept. 4.	N. W. Iowa & S. W. Wis., at Ridot, Ill.	Jonathan Stewart, Sec.
Sept. 12-14.	Tri-State, at Toledo, Ohio.	Dr. A. B. Mason, Sec., Wagon Works, O.
Sept. 18-20.	North American, at Toronto, Ont.	A. I. Root, Sec., Medina, O.
Oct. 9, 10.	Northern Mich. at Sheridan, Mich.	O. R. Goodno, Sec., Carson City, Mich.
Oct. 17, 18.	Northwestern, at Chicago, Ill.	Thomas G. Newman, Sec.
Oct.	Northern Ohio, at Norwalk, O.	S. F. Newman, Sec.
Dec. 5-6.	Michigan State, at Flint.	H. D. Cutting, Sec., Clinton, Mich.

 In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Posey County, Ind., Honey Show.

The twenty-fifth annual fair of the Posey County Agricultural Society, to be held at New Harmony, Ind., on Tuesday, Wednesday, Thursday and Friday, Sept. 11, 12, 13 and 14, 1883. The premiums for bees and honey are as follows :

Stand of Italian bees.....	\$2 00	\$1 00
Stand of native bees.....	1 00	50
Imported or Italian bred queen.....	1 00	50
20 pounds of honey, in comb	2 00	1 00
20 pounds honey, extracted	2 00	1 00
5 pounds beeswax.....	1 00	50
Bee hive.....	1 00	50
Display of apiary imple-		
ments.....	3 00	1 50
Foundation for brood-		
chamber.....	1 00	50
Display of comb and ex-		
tracted honey.....	2 00	1 00
5 pounds honey in comb...	1 00	50
5 pounds of honey, strained	1 00	50
Each exhibitor to arrange and take care of his own exhibit.		

We understand that Mr. J. M. Hyne, of Stewartsville, Ind., will make an exhibit, and we hope others will do so, and that the display will be very sweet and enticing.

 The new Postal Note will be obtainable in a few days at the Post-offices all over the country. Then any sum from one cent to five dollars can be sent in a letter, by obtaining a Postal Note, costing only 3 cents. After October 1, small sums can be easily sent to this office for 5 cents (3 cents for the Postal Note and 2 cents postage on the letter), and there will be no need of sending postage stamps in letters, which often get all stuck together by the damp weather, or being handled while perspiring.

Mailing Queens to Canada.

It has been the practice, for some-time, for breeders to send queens by mail to Canada, and usually they are never heard from after, on account of their being unmailable. A breeder suggested, a few weeks ago, that the rate of 10 cents on samples of merchandise should be paid on queens, and to satisfy him we made a statement in the BEE JOURNAL to that effect. Now, we have an official letter from Joseph H. Blackfan, Esq., superintendent of foreign mails, on the matter. It was written in reply to a question from Mr. J. Rutherford, of Buffalo, N. Y., relative to sending queens by mail to Canada. Mr. Rutherford placed the letter on our desk, for the information of breeders generally. It is as follows :

WASHINGTON, D. C., July 17, 1883.—*Sir:* In reply to your letter of the 14th inst., relative to the refusal of the postmaster of Buffalo, N. Y., to receive, for mailing, a package containing queen bees addressed to Canada. I have to inform you that the transmission of articles of merchandise by mail between the United States and Canada is limited, by the postal arrangement in force between the two countries, to *bona fide trade patterns or samples* (specimens) not exceeding 8 ounces in weight; and that articles of merchandise, such as queen bees, sent for sale, in execution of an order, or as gifts, are not *bona fide* samples, and are not transmissible by mail from one country to the other.

If queen bees have been forwarded by mail between this country and Canada, except as *bona fide* trade samples, they have been so forwarded either through inadvertence, or in disregard and violation of the postal arrangement referred to.

I am, very respectfully, your obedient servant,

JOSEPH H. BLACKFAN.
Supt. of Foreign Mails.

Fairs.—To any one exhibiting at Fairs, we will send samples of the BEE JOURNAL and a colored Poster, to aid in getting up a club. The Premiums we offer will pay them for so doing. For a club of 8 subscribers to the Monthly BEE JOURNAL, or 4 Weekly, we will present Dzierzon's Rational Bee-Keeping, price \$2.00.

Honey Wanted!!—That sounds well. Two weeks ago an advertiser wanted some tons of extracted honey. This week an advertisement may be seen on page 412, calling for tons of comb honey. It can easily be obtained, and the honey this season is magnificent. That is universally conceded.

Dividing Colonies.

The Indiana *Farmer* remarks as follows on judiciously dividing colonies, and the effect of such dividing on honey gathering :

Artificial swarming or dividing is much preferable to that of natural swarming, when rightly understood; but by those who will not stop to think or learn the laws of instinct by which the bees are governed it cannot be successful. Only yesterday we were called upon to hear the grievances of a brother bee-keeper, who had lost almost the entire honey crop of this season, by his manner of dividing. The first principle, the key to success, is in keeping the old bees and the old queen in the new hive. That is where the work is to be done, and where the working bees and queen should be put. In making divisions not more than one frame of brood should be taken from the old hive; then move the old hive to the new location, leaving the new hive on the old stand, thus throwing all the working bees in the new hive where the work is to be done. The few bees left, and those hatching, will be able to do all the work necessary in the old hive until the advent of the new queen. Our friend mentioned above took exactly the opposite plan, and the old hives with all old bees commenced throwing off swarms as fast as the young queens hatched.

Nebraska Bee and Honey Show.

I desire to call the attention of the members of the Nebraska State Bee-Keepers' Association, and all others engaged in apiculture, to the liberal premiums offered by the Nebraska State Agricultural Society in Class VII., entitled "Bees, honey and apiarian goods," and especially the premium of \$25 offered for the best colony of bees. The test of colonies will be net gain, and will be weighed and sealed Aug. 28, and weighed again Sept. 11. Each colony must be the progeny of the queen and colony on trial. All shipments in this department can be made to the Hon. B. E. B. Kennedy, superintendent of Class VII.; and the bees should be on the ground on or before Aug. 27. All other articles may be entered, up to noon of Sept. 10.

M. L. TRESTER,
Sec. N. B. K. Association.
Greenwood, Neb.

 The pamphlet, "Honey, as Food and Medicine," is in such demand, that we find it necessary to print them in still larger quantities, and can, therefore, still further reduce the price, as noted on page 411. Let them be scattered like "autumn leaves," and the result, we feel sure, will fully reward honey-producers for both the labor and the small expense.

Bees and Honey at Louisville.

Under this heading Mrs. L. Harrison, of Peoria, Ill., makes the following pertinent remarks:

It is comforting to know that in some parts of this country at least, if not in Illinois, the production of honey is worthy of a place among other industries. During 1881 and 1882, acting as vice-president of the North American Bee-Keepers' Society for this State, we interviewed the Board, requesting a building, or a separate apartment, for the honey exhibit, also that special premiums be allowed. The prominent bee-keepers of this State, with one exception, responded liberally to the application for special premiums, as did also the editor of the AMERICAN BEE JOURNAL, and those of other States. The request was denied, but a mollifying ointment given instead, by more than doubling the premiums ever before offered for this exhibit. As the present incumbent is a man endowed with a vote, greater things were expected; but in looking over the catalogue for the coming fair, it is apparent that the old ground is maintained, but no more territory is acquired. The great Southern Exposition at Louisville, Ky., (as we see by the Louisville Courier Journal of July 8), appreciates the importance of honey production. It says: "While ever day during the Exposition, from Aug. 1, until the closing, will be full of the most interesting features, certain days have been set apart for special attractions, which will be of direct interest to a large number of people. The programme, on the opening day, will be very elaborate. Business throughout the city will be suspended, and the Exposition will be opened by the President of the United States. On Tuesday, Aug. 28, begins a week known as 'Bee-Keepers' and Horticulturists' week.' Prizes will be awarded, and arrangements have been made by the Kentucky Bee Association to have many hives of many kinds of bees within the grounds." Horticulture and apiculture are Columbia's twins, united by inseparable ties, the severance of which would result in the death of both. Then let the devotees of each worship at the same shrine, regardless on the one hand of the grub in the core, as well as the sting in the narrative of the other.

We were rather astonished when Mr. J. Rutherford, of Buffalo, N. Y., called on us last week, and said he had started for the Louisville Exposition to make an exhibit of honey, but owing to having received the following letter, he had concluded not to go. The letter was in reply to an application for space, and is from the general manager, and reads as follows:

J. RUTHERFORD, Esq.—*Dear Sir:* We cannot accept your exhibit unless you pay \$25 and 15 per cent. of the gross proceeds. J. M. WRIGHT, *Gen. Manager.*

The Basswood or Linden.

The following parody, says the B. K. Magazine, was read at a national convention at Cleveland, Ohio, about ten years ago. The wonderful yields of honey from basswood (linden) taken for three successive years by J. W. Hosmer, Esq., of Janesville, Minn., has made his fame as a bee-master proverbial, and the recital of the facts by Mr. Hosmer himself, so worked upon the poetic feelings of Mr. Whitford, that he at once transformed a sublime poem, recounting the results of the conflict of mighty armies at war into that of a more numerous host busily engaged in pursuing the arts of peace:

On Linden when the sun was low
(All ready were the combs of snow)
The bees began a feat to show,
Of honey gathering rapidly.

'Twas noon—and yet the July sun
Was half bee-clouded by the run,
That streamed to show what can be done
From Mr. Hosmer's apiary.

With tiny trumpets fast arrayed,
Each stinger sheathed her battle-blade,
Nor laggard natives long delayed,
But joined the merry revelry.

Then shook old heads with wonder risen,
As past the bees their teams were driven,
For swiftly through the light of heaven,
Fair flashed the bright Ligurians.

And wider yet their fame shall grow,
On Linden's sweets in combs of snow,
And greater yet shall be the show
Of honey gathered rapidly.

Well, Hosmer saw a splendid sight,
As forth he went to weigh that night,
Commanding John, his man, to light
The darkness of his apiary.

The gain that day, per single hive
Was two pounds less than fifty-five;
No wonder, then, bee-keepers thrive
Who understand their bees' idleness.

The interest deepens. On, ye brave,
Whose work and glory 'tis to save
Our friends, the bees, from cruel grave
Beneath a sulphurous canopy.

Ah! few shall fall, and many meet
Success like this authentic feat,
When every flower beneath our feet
Shall feed some dainty epicure.

The National Convention.

The National Bee-Keepers' Association, will hold its Annual Convention in the City Hall and Council Chamber in the city of Toronto, on Tuesday, Wednesday and Thursday, the 18th, 19th and 20th days of September, during the second week of Canada's Great Fair. All the railroads in Canada will issue tickets during this week, good to return, up to Saturday night 22d, at single fare for the round trip. Special excursion rates will be arranged from various parts of the United States, of which due notice will be given. Those who intend being present may be kept posted on the latest excursion rates,

etc., by addressing me, and also that I may arrange hotel accommodation. Private lodgings will, if possible, be secured for those who desire it, and every effort will be made to make everybody comfortable. A grand meeting is anticipated.

D. A. JONES, *President.*

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL,
Monday, 10 a. m., Aug. 13, 1883.

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The honey harvest in this neighborhood is over, and was very satisfactory every where. Large crops were produced in my immediate neighborhood of bulk extracted and comb honey, and our Kentucky neighbors seem to belong to that favored class of mortals with whom there is no such word as failure. While we had very poor seasons for 5 years in succession, they harvested medium to good crops every time, and this season eclipses all previous ones with them, in quantity. Their quality cannot be excelled. We have had very large arrivals, and, our commission houses being well supplied, the market is overstocked at the present.

There was almost no demand for the last 3 or 4 weeks for our small packages—1 and 2 lb. jars. We sell for table use, and there is a very slow demand for such quantities as are used in barrels for manufacturing purposes. Honey being scarce on the market in such quantities, is sold at all prices, and our friends have the best show in the world for running prices down to a point from which they may be hard to recover.

Our prices, of late, for extracted honey, have been 76¢, on arrival, and for choice comb honey 146¢.

BEESWAX—Has been in fair supply, and sold at 30¢ to 32¢, for good, on arrival. CHAS. F. MUTH.

NEW YORK.

HONEY—We take pleasure in quoting the following prices on honey, obtainable in our market: Fancy white clover, 1 lb. sections (no glass) 20¢ to 21¢; fancy white clover, 2 lb. sections (no glass) 40¢ to 41¢; fair white clover, 1 and 2 lb. sections (no glass) 16¢ to 17¢; fancy buckwheat, 1 lb. sections (no glass) 15¢; fancy buckwheat, 2 lb. sections (no glass) 13¢ to 14¢; ordinary buckwheat, 1 and 2 lb. sections (no glass) 11¢ to 13¢; extracted clover honey in kegs or barrels 75¢ to 80¢; extracted buckwheat honey in kegs or barrels 75¢ to 80¢.

BEESWAX—Prime yellow beeswax 31¢ to 33¢.

H. K. & F. B. THURBER & CO.

CHICAGO.

HONEY—There has been a marked increase in sales this week of comb honey. New crop, prime 1 lb. frames (pure white) have sold at 20¢, when in fancy cases, in a small way, good many sales at 15¢, for some grade 1½ to 2 lb. frames (or prize package) when well-filled and white, 16¢ to 17¢; not quite so well filled, 15¢.

Extracted is still slow, but late receipts have been riper, and there is more inquiry; 9¢ to 10¢, for choice clover; dark and buckwheat, 7¢ to 8¢.

BEESWAX—36¢ to 35¢, for prime yellow.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Gloomy accounts continue to be received from the Southern coast counties regarding the honey crop. In the region of Tulare there is a good yield. Some Tulare comb, crossed and mixed, was placed at 13¢, and, extracted of the crop of 1881 sold at 7¢. White to extra white comb 16¢ to 20¢; dark to good 10¢ to 13¢; extracted, choice to extra white 7¢ to 9¢; dark and candied 6¢ to 6½¢.

BEESWAX—Wholesale, 27¢ to 28¢.

STEARNS & SMITH, 425 Front Street.

ST. LOUIS.

HONEY—New, in liberal offering, but little sold in quantities—held higher; extracted or strained at 7¢ to 8¢, and comb at 16¢. Lots in fancy packages bring more in a small way, while old and inferior sells less.

BEESWAX—Inactive and easy, at 27¢ to 28¢.

W. T. ANDERSON & CO., 104 N. 3d Street.

CLEVELAND.

HONEY—New honey continues in good demand at 18¢ to 19¢, for choice 1 lb. sections, and such are readily placed as fast as received; 2 lbs. not so active, at 16¢ to 18¢. Second quality sells 14¢ to 17¢. Extracted, not in demand.

BEESWAX—None in Market.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

We quote our market prices, as follows: White clover, one lb. combs 20¢ to 22¢; white clover, 2 lb. combs 18¢ to 20¢; extracted from 19¢ to 16¢.

BEESWAX—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatham Street.

CORRESPONDENCE.

For the American Bee Journal.

Miscellaneous Experiments.

FRANK R. ROE.

1. Some are in doubt as to whether a swarm of bees will issue from a hive and go off without settling; but they undoubtedly will, sometimes, and that, too, oftener than some estimate, as it has been placed at not more than one in every hundred. For several years past, we have had a swarm or two (out of no more than 25 or 30) to "try it," and they succeeded pretty well this season, as we had a large swarm to come out, and I saw them issue; I watched for the queen, but did not get her, and they started off immediately. I succeeded in cutting off about one-third of them by throwing part of a "potato patch" at them, but the rest seemed determined to go, and I was just as determined to see where they were going; so I followed after them two miles, over fences, through flax, oats, barley, corn, woods, logs and brush, and had to ford a river besides, and then did not get them, but I found out that they did not intend to just go a little ways, and then settle before going to their new home. The entrance to the hive they came from is $\frac{3}{8}$ of an inch wide by 8 inches long. They had a pure Italian laying queen with them. Oh, yes! I must tell how long it took me to go the four miles—two there and two back—it took just three-quarters of an hour. The reason I came back in such a hurry was, I had left a swarm hanging on a limb in the bee-yard, and the bees I had cut off from the swarm that went to the woods, settled with them. I had only been back about a minute when they began to come off the cluster. I grabbed a basket, rushed up the ladder, which had been placed there before; shook what few remaining bees there were in it, then poured them in the hive they came from, and by throwing water at the remainder, while they were low, and clubs after they had got out of the reach of water, we succeeded in settling them again.

MORAL.—When a swarm tries to go off, it does not pay to give up until the last minute.

2. I had a queen to hatch, after which the cap to the cell sprung back, the bees then sealed it up and swarmed. There was no other cell, and no larvæ in the hive.

3. After a queen had hatched from another cell, a worker bee was sealed up in it, and I had another case where a colony was building cells and sealed a worker up in one. Why did not those workers gnaw out the same as a queen? They were both dead when I found them. If I had not peeped into the last mentioned cell, I would have inserted it in a nuclei, and waited for a queen to hatch.

4. When I am in doubt as to whether a cell is good, or do not know when it will hatch, I open it on the side with a sharp knife and look in, then seal it up again, and if a good job is done, the occupant will never know the difference, but a good job must be done, or the bees will tear the cell down. It can be done by warming a knife blade and running it over the place. I have taken queens out into my hands three or four days before their time to hatch, and then put them back and sealed them up, and they hatched as if they had never been disturbed.

5. I had two swarms issue at once and settle together, and as they settled on the body of a tree, I smoked them into a nail-keg and tied burlap over the top, so that I could bring them down. As dinner was ready, I set them in the shade, and when I came back, you may just guess the temperature was "up" in that nail-keg. The most of them sought refuge in the bottom, without finding it. When I poured them out they were wet all over with honey, and the honey also ran out of the keg in a stream. They had taken it from the hive before swarming, and when they began to get too hot, they disgorged it. There was scarcely any of them dead when I opened the keg, but they nearly all died soon after.

6. The reason why some swarms will sting, and others will not while swarming, is this: If the hive from which they issue is well filled with honey, they will fill themselves before coming out, and a bee, gorged with honey, will not sting from choice; while upon the other hand, if there is scarcely any honey in the hive when they swarm, they will not be filled, and are in perfect trim for stinging.

Jordan, Ind., July 25, 1883.

Read before the Texas Association.

Comb or Extracted Honey.

W. K. MARSHALL.

The question whether comb or extracted honey will pay best, is one that is attracting the attention of bee-keepers. To decide this question we must take all the surrounding circumstances into consideration. It is admitted that comb honey will sell higher than extracted. In a locality convenient to market, where the honey would not have to be transported any distance, or handled often, it might be doubtful which would pay best. It is admitted that bees will gather more extracted honey than comb; with comb foundation, however, the amount would not vary so much. Say that a colony would produce 100 pounds of comb honey, and that it would bring 20 cents per pound, making \$20, it would require the same colony to produce 200 pounds at 10 cents to bring the same amount.

The expense in producing the comb honey is greater than that of extracted. The sections and cases in which to pack it, would cost say 2 cents per pound. The difficulty in transporting comb honey any distance

to market, is so great that for those at a distance from market it amounts almost to a prohibition. I have never been able to transport comb honey any distance without having it broken and injured, so as materially effect the sale. I believe the only way to market comb honey safely is to go with it, and handle it yourself. Taking into consideration the additional expense of producing comb honey, and the difficulty of getting it to market, I am convinced that our true policy is to work for extracted honey. There may be exceptions to this rule; there may be localities where there is a demand for comb honey, and not much for extracted honey. The demand for extracted honey has been largely on the increase, and there has been more and more demand for it every year. I believe the demand for it will very soon be unlimited. The ease and comparative cheapness of sending it to market, and the fact that a colony will produce decidedly more honey, all combine to point us to extracted honey as our principal production. We can, for the present, find a market for all we will produce near home. Extracted honey, at present prices, will pay. Anything like a good colony ought to produce 100 pounds, which, at present prices, would be \$10. This, after deducting all expenses, ought to clear \$5. This is a moderate calculation, and I think could be realized with anything like good management.

Marshall, Texas.

For the American Bee Journal.

Italian and Hybrid Bees, etc.

S. A. SHUCK.

I have found bees in the timber in Ohio, Iowa, Kansas, Missouri and Illinois. Seven years ago last April, I purchased my first colony of bees for the purpose of studying and practicing modern apiculture. They were the so-called brown bees, in box hives. My first young queen mated with a hybrid drone, giving me bees that, one in every 25 or 50 showed the so-called second yellow band. Since then, I have had hybrids of every grade, from black and brown queens to Italian queens. I have owned black, brown and Italian bees, that at certain times in the season I could, without difficulty, handle without smoke, while many of the same bees, at other times, were intolerably vicious when disturbed. I have to-day, in my apiary, Italian bees, or those showing all the necessary markings in color, and that, too, without the window or "studing" tests; that with honey coming in, as it is, in abundance, can be called amiable and well behaved, but under destitute circumstances, it is almost out of the question to handle them without protection. I have others, Italians, that in all weather that is fit to handle bees at all, and from the point of starvation to honey in the greatest abundance, can be handled without smoke or protection.

In 1881, I had as fine hybrid bees as could have been found anywhere. They were excellent honey-gatherers and comb builders, produced in the same way that the "celebrated red clover strain," mentioned in the BEE JOURNAL not long since, was produced, by crossing the large Italians with the brown bees; that is, I guess, they came in this way, as they were the Italian queens, producing very large hybrid bees that were gentle and "boss" workers when there was plenty of white clover and basswood. The stripes on them were very dark, and much smaller than "kittens," and they did not have very long hair on their "hind legs," and when the extremely hot and dry weather set in, they "sat" in (their hives); while our Italians that did not appear to do near so well during clover and basswood, went far and near visiting every nook and corner in search of the scanty bloom; maintained their stores and gained a moderate supply for winter. These hybrids consumed their stores in brood-rearing, and for winter supplies had plenty of bees and empty combs. This was not all, shortly after the bloom failed, two of those hybrids swarmed, another two balled and killed their queens, but the Italians "toiled leisurely on."

In 1880, a friend and I purchased a selected imported queen, that I have mentioned before in the BEE JOURNAL. She was one of the most prolific queens I have ever seen, but her bees, which were gentle and excellent workers, spent nearly all their energies in the early part of the season, in brood-rearing. They were the most excessive builders of drone comb I ever saw, and while other queens in my apiary refused to lay drone eggs until their hives were crowded with bees, this queen would occupy every available cell.

For these reasons I discarded the imported stock. Besides the qualities of the imported stock, the bees were small and the drones very dark. I made the discovery in June, 1881, that I was losing ground by breeding from imported stock, and during the remainder of the season I disposed of all the daughters of the imported queen but three. During July and August, 1881, I reared several queens from the best home-bred stock I had, for the express purpose of producing my drones in 1882. In the spring of 1882, drone combs were excluded from the few colonies of hybrids and imported stock, and supplied in abundance to those from which we wanted drones. Our queens of 1882 were all reared from four home-bred queens. About 10 per cent. of our queens mated. The hybrids were all destroyed last fall. Two queens were superseded late in the fall, and the young queens both mated, one of which was destroyed this spring, so that, to-day, in 56 colonies, we have but one hybrid queen.

For two reasons I have given the above short history of my efforts in breeding for good bees.

1. To give the reader some knowledge of my experience with bees.

2. That a comparison of my experi-

ence with that of those whose experience appears from time to time in the BEE JOURNAL, and who are advocating hybrid bees may be had.

It is not my intention in this communication to discuss the merits or demerits in a definite way of either hybrids of Italians, but I wish to drop a few hints that may tend to encourage apiarists to think solidly for themselves, and not allow others to think too much for them; and to do this in a practical way, I will introduce a question here. If such a happy hybrid cross can be "hit upon" so easily as some of our bee-keeping friends are contending for, why is it that, with Italian bees in this country for more than 25 years, our most prominent breeders have never made the discovery? And, again, if such hybrids are so easily produced, why is it that younger apiarists like myself and hundreds of others who are readers of the BEE JOURNAL, cannot produce the same results, especially when we have the instructions how it is done repeated over and over again to us?

These hybrids have been represented as the "celebrated red-clover strain," and "the coming bee;" yet the reports in honey from those having this "celebrated" stock are no greater than the reports of novices. Italian bees from my apiary, numbering 100 colonies or more, have worked on red clover every season since I purchased them. I have not had time yet this season to visit the fields, but some of my neighbors told me yesterday that the yellow bees were working on the red clover "thickly." Hybrids from our bees, as would be expected, work largely on red clover, and I do not see why hybrids from any other good strain of Italians should not work on it.

One thing about red clover, but few apiarists seem to have realized, and that is its failure to secrete nectar. Our bees have worked on it best when the weather is warm both day and night, and making the most thrifty growth. Cool nights stop the secretion of its nectar, and there are but few plants that fail as quickly in dry hot weather as red clover.

Bryant, Ill., June 18, 1883.

For the American Bee Journal.

The Humidity Question.

S. CORNEIL.

The relation of the humidity of the atmosphere to the mortality of bees in winter, is referred to by the writer of "Bee Notes" in the *American Agriculturist* for January and February last, and quotations therefrom appear on page 68 of the present volume of the BEE JOURNAL. After very fairly summarizing some points in an article of mine on page 728 of the BEE JOURNAL for 1882, he says:

"The writer then asserts that in those winters most remarkable for bee mortality, the air has been very moist. We have the data whereby this can be determined, as in this place the condition of the atmosphere

as to moisture has been recorded daily for 19 years. We will compare the figures with the loss of bees, and give it to the readers of the *American Agriculturist* in February. If this be true, it shows well why sub-earth ventilation has been so successful, as by that method the air is kept from getting moist. The appearance of the bees that die of dysentery is also favorable to this view. They look dropsical, and seem fairly oozing with liquid excreta."

In his "Notes" for February, he says: "An examination of the condition of the atmosphere, as to the point of saturation, shows that there is not the least evidence in favor of the idea that excessive moisture was in any single case the cause of the great losses of bees. It also appears that in all the seasons of bad wintering, severe cold was experienced. It is further shown that when the cold occurred early in the winter, the mortality commenced at an early period. If late, the bees did not appear diseased till near the end of the winter."

I find no fault with the criticism, but the records examined must have been very different from those of the Signal Service in connection with the War Department at Washington. The Chief Signal Service Officer of the United States Army has, at the expense of a great deal of trouble and labor, very courteously supplied me with data from which I have compiled the accompanying table, an examination of which will show that at most points the humidity, as well as the cold in the winter of 1880-1, was excessive. The temperature for each month of that winter has been compared with the monthly average at each station since it was established, and so with regard to the relative humidity. In the columns for temperature the figures preceded by the minus sign indicate that the temperature was so many degrees colder than the average. Those having the plus sign signify the reverse. In the columns for humidity, the figures preceded by the plus sign indicate that the moisture was so much in excess of the average, dry air being represented by 0, and the point of saturation by 100. Those having the minus sign show that the air was so much drier than the average.

The way in which cold and moisture affect bees injuriously in winter, I conceive to be somewhat as follows. But first let me say that I think it is fully established that the temperature of a cluster of bees is not constant, like that of mammalia and birds, but varies, through a considerable range, with the temperature of the surrounding air, yet never falling as low, as in some of the lower orders of the cold-blooded animals, without producing death. It is also established that bees do not hibernate perfectly, but are at all times more or less active and consume food, and that this activity and consumption of food are increased by severe cold. Since severe cold reduces the temperature of the bees, the air permeating the cluster will also have a lower temperature, and will, in consequence, have

TABLE—Showing the average Temperature and Relative Humidity during the Winter Months, also the Monthly difference from the average, and the total difference for the winter months at the respective Stations during the winter of 1880-81.

less capacity for evaporating the water from the bees, and may be incapable of taking up the larger quantity produced in consequence of the low temperature, unless the air is undergoing constant change by proper ventilation. This evil will be very seriously increased, if the external air is already overloaded with vapor, for the more humid the air the less its capacity for absorbing more water. But a moist external air increases the trouble in another way. We all know that the cold of a damp day is more felt than that of a colder dry

one, because the humid air, being a better conductor, the heat of the body is carried off more rapidly, and so with regard to the bees. A damp external atmosphere tends to reduce their temperature still lower, and aggravates the evil first mentioned.

If these views are correct, the losses in 1880-81, in some parts of the country (the eastern part of the State of Maine for instance), should not have been much greater than usual, because there the table shows the temperature and humidity were about normal. Dr. Finker collected more

information regarding the losses of bees and the attendant circumstances that season than any other private bee-keeper. Probably his reports would show the localities in which the losses were least, and those in which they were greatest. It would be interesting to know if a comparison of his reports with the table will show that the localities in which the losses were heaviest correspond with those in which the humidity was greatest. If the reports collected by the editor of the BEE JOURNAL were classified, as to the humidity of different localities, I dare say they would throw light on this branch of the subject.

In connection with the foregoing table, I invite attention to the statement that "in winters, when the cold occurred early, the mortality commenced at an early period; if late, the bees did not appear diseased till near the end of the winter." In this part of the country it was just the reverse in 1880-81, and I would almost venture to say that the reports will show that such was the case generally. The table shows that the cold was most intense in December and January, and that it moderated in February and March; but that, as it did so, the humidity increased to excess in the two latter months. On the 6th of March, I had 4 colonies dead, out of 44 packed in chaff, on Mr. Townley's plan. Before the swarming season came around, I had only 13 good ones and 6 nuclei left. The report of Mr. Geo. Garlick (page 158, BEE JOURNAL for 1881), whose apiary is located about 50 miles east of this place, very fairly shows how the bees died in this part of Canada. On Feb. 1, he had 137 alive, out of 140, on their summer stands, some being packed in sawdust. On March 1, he had 88 alive; on the 6th, 62; on the 15th, 55; on the 1st of April, 42; on the 10th, 12, and on the 6th of May, only 7 were left of the whole lot.

From an inspection of the table one would think it should not be much of a trick to winter bees in some localities, the neighborhood of Cincinnati for example. The ventilation and protection sufficient for hives in that locality would be quite inadequate for the climate of Port Huron or Toronto; the average winter temperature at these points being about 13° colder, and the average relative humidity being over 80°, while at Cincinnati it is less than 68°.

Many other interesting points might be considered, but I trust the table will assist the readers of the BEE JOURNAL to form opinions for themselves, as to the two most important elements of the climate in which they have to winter their bees, and whether they are most injured by severe cold or by cold and excessive moisture combined; the former being present in the early part of the winter of 1880-81, and the latter occurring towards its close.

Lindsay, Ont., June 22, 1883.

For the American Bee Journal.

Two Queens in a Hive.

W. H. SHIRLEY.

There seems to be quite a number of reports of two queens in one hive, this season. I have instanced two queens where the bees were superseding a queen. In the following letter which I have received from J. O. Shearman, he mentions having two queens in a hive:

Our bees seem to not be doing much since the nights turned cool, though button willow is just opening, it does not seem to yield much. I guess it is because the water is so high yet, as to flood it. Bees go to it a little, and then run on red clover the rest of the time. I had a case of two queens in a hive. I saw them both on the 2d of August, on one comb, and not excited at all, and did not seem to notice each other. I had clipped the old queen's wing, to avoid swarming, and I guess I slashed her pretty severely, as I did it with my knife, not having the scissors handy. I think they undertook to supersede her, as I found queen-cells cut up on other combs, or she might have swarmed and then crawled back. She appeared to be "slimmed up," as we used to call it, same as for swarming. The young queen was the largest and brightest colored. What was the cause of your two queens in a hive? Do you know? I left both of mine in, to see how they made out, as they both seemed quiet. How would it do to answer in the BEE JOURNAL the cause of yours? If you do, you might send this in too. I look for a fall run of honey yet, as feed of all sorts is fresh, though the ground is fast getting dry. J. O. SHEARMAN.

New Richmond, Mich.

The case in the BEE JOURNAL, page 373, was of a different kind. I had introduced a young queen, after killing the old one in the hive. Quite a number of young queens get lost on their bridal trip, from nuclei, on an average say 10 per cent. of them. Now, I think it was one of these queens that dropped down by this hive, where I had introduced one some days before, and was received by the bees all right.

I have found three young queens balled in front of the hives, this season, and in swarming time I frequently find one and two young queens that the swarm had caught when on the wing.

Glenwood, Mich., Aug. 8, 1883.

For the American Bee Journal.

Instinct Compared with Reason.

W. H. STEWART.

Volumes on volumes have been written concerning the organization, powers and doings of the honey-bee without in any way exhausting the subject. The field is unbounded, and ever fruitful. The song of the grove, the aroma of the flowers, and the industry of the bee, have ever been favorite themes with the poet. Dull indeed must be that class of persons who experience no pleasing and inspiring emotions, who are able to read no new and useful lessons from the many facts of pleasing interest that shine out like so many golden threads, so beautifully woven, all through and through the warp and woof of plant and insect life, and more especially that of bees and flowers. How wonderful each new phenomena manifested on every hand as we contemplate the ample field—in the co-relation and inseparable interblending of the vegetable and animal kingdoms; their mutual dependence on each other for the power of reproduction, etc. The new born honey-bee, inexperienced and independent of all instruction, reads on the page of instinct the truth that it is altogether dependent upon vegetable fruitfulness for the only food that can sustain its life.

The plant also, through all its manifold changes from earliest germination in spring-time, feels the delicate touch of the vibrating chord of inter-dependence; and guided by the same law that gave birth and direction to instinct, unfolds its form, ever taking on new and more complex conditions, slowly, yet surely, concentrating its own best life-juices in the forming of the pure nectar to be negotiated with the yet unborn honey bee for a precious morsel of fertilizing pollen.

As we muse, blending our life with these truths, our soul drinks at the fountain of harmony that vibrates along this æolian chord that whispers instinct to the little speck of animate life at its one end, and law to the unfolding plant at the other.

Could we draw aside the mystic curtain that seems to divide between the human and insect planes of life, we should, perhaps, learn that the common Creator had in no way been partial in the bestowal of blessings on his creatures. We would be likely to discover that where one power had been withheld, another, of more vital importance to the individual, had been given.

Man may boast of his reasoning powers, and claim to be the "lord of creation," and to be the rightful possessor of the summit plane of animated life. How few who engage in mechanics or commerce become successful masters even after the labor and experience of many years; yet the little honey-bee emerges from its cradle a master mechanic, able also to move off in the right direction to do its part in obtaining a livelihood for itself and its fellows.

Not only so, but the bee may rightfully claim a more striking superiority over man. At its birth the bee is endowed with the power to step upon the plane of equality with its fellows; to hold and enjoy every right that can in any way enhance the happiness of itself and the colony; able and willing, from birth to old age, to do its part in the support of a regularly-organized government, that administrators all needful rights to all concerned. A government that gives full satisfaction through thousands of generations without the necessity of the repeal or modification of a single rule or law.

Should not reason hide its blushing face when it remembers that after thousands of generations of men have labored to discover and frame a government that would give satisfaction to all its members, they have failed to make one rule, or enact one law against which some one or more of their fellows would not rebel.

"Raise reason o'er instinct as you can,
In this 'tis God directs; in that 'tis man."

Could bees impart their knowledge by the use of human language, would we not do well to sit in quiet silence and learn wisdom as spoken from an instinctive standpoint? It has been said that "actions speak louder than words," be this as it may, "one truth is clear." The careful observer may glean many fine and important lessons from the works, habits and unfoldings of the lower forms of life.

O, for the power to penetrate,
Or lift the mystic veil,
And scan each creature's full estate
As each their mission fill.

Granite, stratum, or verdant plane—
Insects, beasts, birds, man,
Trace along the unbroken chain—
My mission in the plan.

To best improve what me is lent,
Nor covet what's withheld;
Act well my part and be content,
In life's most fruitful field.

Orion, Wis., Aug. 2, 1883.

Ohio State Bee-Keepers' Convention.

The Ohio State Bee-Keepers' Association will hold a convention during State Fair week, commencing on Tuesday evening. The following programme has been arranged:

Tuesday Evening, Sept. 4.—1. Greetings and organization. 2. Annual report of Secretary and Treasurer. 3. Election of officers. 4. Annual address of the President. 5. General discussion of topics presented by members present.

Wednesday Evening, Sept. 5.—1. Address by S. D. Riegel on improvement in bee-culture as deduced from the season's operations, followed by discussion on the same. 2. Question drawer and discussion on topics presented.

Thursday Evening, Sept. 6.—1. Address or general talk by Vice-President Aaron Benedict, on the rearing and management of queens, followed by discussions of the same. 2. Question drawer and discussion of topics presented.

Conference meetings of bee-keepers and those interested will also be held

each afternoon at 1 o'clock in Apiarian Hall, on Fair grounds.

The place of meeting of the convention to be decided at time of the Fair, probably in the upper room of Apiarian Hall.

Everybody who is at all interested in bees is invited to meet with the Association, and all who can bring articles for exhibition, as efforts are being made to render this department a grand success.

The State Board of Agriculture has furnished the bee-keepers a separate hall for their exhibits at the State Fair, with an upper room in which to hold meetings. Ample room will be furnished for all exhibits.

Dr. H. BESSE, *Pres.*

D. SPEAR, *Sec.*
AARON BENEDICT, *Sup't. Apiary Hall.*

For the American Bee Journal.

Marketing, and Price of Honey.

JAMES HEDDON.

As our editor has told us in a late number of the BEE JOURNAL, "supply and demand" is the great cause of fluctuations in prices of all commodities, yet sometimes immediate ups and downs in prices are caused by sentiments flowing across the minds of producers; sometimes almost creating a panic in prices.

It is my opinion, at this time, that bee-keepers over the country generally have too much of an idea that our present crop is going to be enormous, and sell at a low figure. I got frightened myself, and put 200 pounds of comb honey on our market in the shape of an out and out sale, 2 cents lower than I need to have done. There is \$4 charged up to scare.

There is a considerable quantity of honey produced about here this season, notwithstanding the fact that we have not an average crop, because of the improvements in methods and fixtures. The crop coming in rather late, a good many country producers held off from putting honey on this market from the fact that so much was produced here in my apiaries. The merchants have held up the old-time prices, which, from all indications, will carry through the year. Notwithstanding I have been very busy with many other duties besides marketing honey, duties that most other producers do not have, I have thought it a duty, and have taken upon myself the burden of manufacturing honey stands. These I made with sloping shelves for jars of extracted honey, and case in top with glass front, and back door for comb honey. I have introduced, and am keeping supplied one of these in each of the principle groceries in our little city. By this means I hope to market 3 times as much honey at home as I did last year, even at the same price.

Two things make honey sell rapidly. First, putting up and keeping it in attractive shape and place; and second, reducing the price. Between the two I believe that the first is the best card for the producer, and is far less expensive. Let all honey pro-

ducers do this as far as possible. Let them also be in no great haste to market the crop. Honey sells best in cool weather, and is by no means a perishable article, and even grows of better quality if properly kept.

While there may be honey enough to glut the market of a month, it is my opinion that there is not enough to overstock the markets of the year. All we need is to act as a body, and put our honey into market along as demanded, at a reasonable price, instead of panic-stricken like, rushing it all in at once to catch what we believe to be the highest price, which will almost surely turn out to be the lowest price for us.

The best guide I can think of to be governed by as to when to put honey on the market, is to market it only when it seems to be called for at reasonable prices. This, of course, is owing to quality of honey and location. I will give you my own individual standard. We live in a pretty good honey-producing locality. We raise more honey than can be consumed at home. Some of it must be shipped to the great cities of this and other countries.

When I realize 18 cents per pound (it then sells at 20 cents retail) for a nice article of comb honey in one-pound sections, or 25 cents per pound in half-pound sections, and 15 and 20 cents per pound for colored fall honey in one and half-pound sections, and 12½ and 10 cents per pound for extracted, early and late, I am ready to supply such demand, not otherwise.

Just a word regarding half-pound sections. I intend, when the season is closed, to give the benefit of the experiments my class and myself have made regarding half-pound sections. How we like them, how the bees like them, and how my customers like them; also regarding honey boards, cases, broad frames, and various other things. But will say just here that the half-pound sections seem to be a great favorite in the markets around about our little country towns.

Dowagiac, Mich., Aug. 8, 1883.

For the American Bee Journal.

Excellencies of the German Bee.

A. W. OSBURN.

While the praise of the different races of bees, the Italians, the Holy Lands, Cyprians and others is being sounded far and wide; and while the best talent of our country is being engaged to bring more prominently before the public the superior qualities of the above named races, there are but few that have the boldness to come forward and advocate the good traits of character of the German bee (not the black). I know that one who has the independence to advocate the good qualities of the German race of bees, must expect to call down upon his head the scorn, the disapprobation and disgust of the great mass of bee-keepers of to-day.

Let us go carefully over the ground and see if the German bees have not some traits, that the honorable bee-

keeper is bound to respect. In the first place they excel as comb builders; they excel as rapid workers to draw out foundation; they excel as pioneers to strike out from the brood-chamber (and out of the queen's way) to store their honey; the queens thus having no honey to bother them, can fill their combs from top to bottom, and from end to end; they excel in keeping their hives full of workers to gather the crop; all other conditions being favorable, they excel as non-swarmer, when you give them plenty of room.

While I would not wish to be understood that I think the German bee possesses all the good traits to be desired in "the coming bee," yet I would wish them to have credit for what good there is in them; and that their good qualities shall not be ignored when looking around for material to make up that long-looked-for *Apis-Americana*. I am satisfied, from my own experience, that the crossing of the different races makes better business-bees than either bred pure. It is our intention to try the experiment of mixing the best strains of Italians, Germans and Holy Lands together, and see what the coming bee from these three races will be. I have no fear of the result; there is not one of the three but what have excellent qualities, but the fine point is to combine them all in one.

I am aware that some of our most successful apiarists are prejudiced against the German and Holy Land bees, but let them dispute the good traits I have mentioned in the Germans, if they can, or the prolificness, fleetness of wing, and ambition of the Holy Lands. For me to advocate the good qualities of the Italians would be for me to take up your valuable room for nothing, for they are too long and favorably known; but for me to say that they possess all the requisites of what we will wish "the coming bee" to possess, would be as foolish as the other.

Water Valley, N. Y.

For the American Bee Journal.

Finding the Queen.

F. M. CHENEY.

My method of finding the queen in populous colonies of black bees is as follows: Early in the morning, I go to the colony containing the queen I wish to supersede, and divide it, placing half the combs and bees into an empty hive. In a few minutes one of the hives will show queenlessness by the bees running over the front of the hive. I place this hive on the stand, and take the other, which contains the queen, several rods away. Near night this hive will be so thinned of bees that the queen can be easily found, and after obtained, the bees can be returned. I concluded one swarm was queenless, but by dividing I found it was not, and captured the queen which had ceased to lay, although she was only one year old, and had been prolific previous to this.

South Sutton, N. H., Aug. 1, 1883.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Getting Bees Out of the Cases.

Will Mr. Heddon please tell us how he gets the bees from the cases when he takes them from the hive?

SAMUEL FISH.

Milan, O., July 31, 1883.

ANSWER.—Our method of getting bees out of sections is as follows: Now, you will remember our sections all have open tops, and the opening is $\frac{3}{8}$ of an inch wide. When we uncover the case before removing, we blow the smoke between the sections, by passing the nozzle of the smoker across each row, as we press the bellows. Four repetitions of it, in rapid succession, starts nearly every bee downward. Inclined to fill himself with honey, and there being none uncapped above, he immediately starts below. We now blow with our mouth a lively cool blast across the ranges, the same as we did with the smoker. This drives them more than smoke, after being smoked. Now, as you lift your case, there should not be more than 40 to 100 bees left in it. Next we remove the case to our 6 foot square summer house; the upper half of which is wire cloth all around, and two of its sides are doors. In this house we pile up the cases crosswise to each other. The bees immediately go on to the screen, which screen is double, and prevents the feeding of outside robbers through the net work. Now you can remove the cases to the honey house free from bees. Throw open the doors and the bees return to their hives. In place of such a screen house, a revolving window, or similar device in any room, may be used.

Comb Foundation for Surplus Honey.

MR. HEDDON:—In the BEE JOURNAL of July 25, replying to W. B. Dresser, of Michigan, you say: "I use full size pieces of foundation," etc. You were referring to section boxes. Do folks generally eat comb honey made on comb foundation? Somehow I was under the impression that it is not very clean or wholesome, and was only intended for brood and extracted honey. I think I should bite it with my eyes shut, and not smack my lips much. But then, it may be I am prejudiced just a little, and not in the spirit of advanced and enlightened bee-culture. I use foundation, but in the brood-chamber, with a very small bit in the honey boxes for a starter, not enough, you know, to

hurt; and may be you will say, not enough to do any good, either. Please say something about this article (foundation) as to its purity as food, etc.

W. P. HANCOCK.

Salado, Texas, July 30, 1883.

ANSWER.—My rule in selling any commodity to my brother man, is the one laid down by that great and loving reformer, Christ. "Do unto others as ye would that they should do unto you." Almost all will admit that it is our duty to do so; but all do not see the fact that we likewise owe a duty to ourselves, and it is a second duty, to stop right there, in very many instances.

For three years, and at a time before manufacturers were making a very delicate foundation for surplus combs, or, at least, before I obtained any, I used full sheets of foundation in all my sections. No person in this county, except myself, knew there was such a thing as comb foundation. I sold this honey in my home market readily, and only one person during that three years ever made a remark regarding it, that came to my ears. Getting hold of an unfortunate piece, one man observed: "That honey I got of you seemed to have too tough a comb." Large numbers spoke the praises of my comb honey. So much for the effect upon the trade.

Now, in regard to the healthfulness of wax. So far as I can learn, nothing is more wholesome to take into the stomach than honey comb. Being perfectly indigestible by the human stomach, no effort is made to digest it. In eating warm biscuit, the particles of comb intermingle all through the dough in such a manner as to give the gastric juice of the stomach a better chance to do its work. Particles of wax are smooth, not harsh or irritating to the stomach or intestines, and the chemical effects are said to be slightly stimulating.

Now, as regards cleanliness of the foundation. Of course to persons who do not know what they are eating, if there are no ill effects, no harm is done. To those who do, and who are prejudiced against it, as Mr. H. may be, allow me to say, let us reason together. Trusting that the reader knows chemically of what impurities consist, we will pass by, asserting that high degrees of heat destroy all impurities. The degree of heat which is brought to bear, when rendering wax, destroys all impurities that may be lurking about the combs melted. I consider that when properly ren-

dered, beeswax is as pure and wholesome for chewing gum as any nugget found upon the spruce tree.

Since I have been making comb foundation, and receiving students, I have had a large number of assistants in the wax room, and I have never had one but was more or less of the time chewing scraps of wax. Neither have I ever had one, who has been with the honey, from the cake of beeswax to the delicate white combs upon the table, who splenored against the use of comb foundation for surplus honey. What is good enough for me is good enough for my customers. What is not good enough for me, is not good enough for my customers.

Kentucky Bee and Honey Show.

The Kentucky State Bee-Keepers' Association will hold its annual meeting in Louisville, Ky., Aug. 29 and 30, at the Southern Exposition building. We hope to have a large attendance of the bee-keepers of the State, and also of other States, both North and South, as the convention will be in session during the week of the Honey and Bee Exhibit. And premiums amounting to \$60 are offered by the commissioners of agriculture of Kentucky, for Kentucky honey, and \$40 by the Exposition, for the finest Italian bees in Observatory hives. The premium on bees is open to the world, and we hope to see a fine display.

The Bee-Keepers' Convention and Honey and Bee Show will be held in the same week of the great exhibition of fruit, for which over \$2,000 in cash premiums will be paid.

We extend a cordial invitation to all bee-keepers' societies, to editors of bee publications, to honey-producers, and queen breeders, and all who are interested in apiculture, to be with us. We hope to have the father of modern bee-keeping with us, the Rev. L. L. Langstroth, to whom a cordial invitation has been given.

Reduced fair on all railroads, both North and South, will be offered to all who attend the Great Southern Exposition. It will doubtless be the grandest exposition ever held in the United States, in magnitude, and nearly equal to the Centennial.

N. P. ALLEN, Sec.

The Northwestern Iowa, and Southwestern Wisconsin Bee-Keepers' Association, will hold its next meeting on Sept. 4, 1883, at John Swanzy's, 2 miles South of Ridot, Stephenson County, Ill. There will be facilities to take persons from the station to Mr. Swanzy's.

JONATHAN STEWART, Sec.

Do not let your numbers of the BEE JOURNAL for 1883 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

SELECTIONS FROM OUR LETTER BOX

Bees Feet Disabled.

I send eight worker bees (taken from as many hives) with clogs of something on their feet. Is it from some blossoms they are working on? I have kept bees now for ten years, but never saw the like before. The bees are carrying these all out of the hives. I find the most of these clog-footed bees in the colonies that are working the strongest. Bees have not done much since white clover bloom, until to-day, when they are working very brisk through the middle of the day. Please let me know through the BEE JOURNAL what it is on the bees' feet. Will it amount to enough to reduce the colonies? If so, what is the remedy? I had an immense run on clover.

E. J. SCOFIELD.

Hanover, Wis., Aug. 6, 1883.

Enclosed find foot, leg and something else. Two of my colonies of bees are affected, as you will see, by the foot and leg, as it is the foot and leg of a bee. Please examine and tell, in the BEE JOURNAL, what it is and the remedy. DR. J. COOPERIDER.

Taylorsville, Ind., July 31, 1883.

[The objects attached to the feet of the bees, are the pollen masses of milkweed (*Asclepias*). The bees visit the flowers for the nectar which is abundant, but the arrangement of the parts of the blossom is such that they cannot gain access to the sweet fluid without coming in contact with a sticky substance at the end of these pollen masses, which are thus pulled out and carried from flower to flower. There is no cure except the destruction of the plants.—T. J. BURRILL.]

Not Half a Crop of Honey.

My brother and I represent 400 colonies of bees, which have been handled scientifically for comb honey, in the best section of this State. The beginning of the honey flow was grand, but the sudden cut off ten days ago, has made it a certainty that not a half crop will be taken.

E. A. MORGAN.

Columbus, Wis., Aug. 2, 1883.

Cyprians for Honey Gathering.

Up to noon, to-day, I have, this season, taken 385 lbs. of pure white honey from one colony of Cyprians; the honey is remarkably fine, clear and heavy. For the last five days, particularly noted, the daily yield has been from 10 to 12 lbs., and I reasonably expect 400 to 500 lbs. of white honey, this season, from this colony. The queen is not yet a year old; she has had no help from any other of my 85 colonies in the same yard or from any other source; every bee of the colony that has aided in producing this 385

pounds, has been hatched from her eggs, and, besides, I have made 7 nuclei from her, and her young queens appear equally promising. Basswood bloom has been good, but is getting past its best now. White clover has been abundant. This locality has had a good honey harvest, notwithstanding the heavy rains and cool weather. There are about 500 colonies of bees kept within the area of half a square mile, and large apiaries within a few miles, are all prospering this season.

GEO. M. LAWRENCE.

Warsaw, N. Y., Aug. 7, 1883.

Bees in Georgia.

My bees are doing better than they have in several years. Up to June 1, they did not do much but swarm, but during the month of June they stored honey fast, and then it set in dry, and they did not do much for a while; but at this writing they are making the air sing with their delightful hum, and I am encouraged with the prospect, and am going to begin extracting in a few days. I have 76 colonies in fine condition; some of them have no room for brood rearing, and I must give them room. There is no other person with the movable frame hive in this section but myself; they say they cannot have luck with bees, but if they would take the BEE JOURNAL a few years, and use some *pluck*, they would have luck. I delight in working with bees, and am always glad to see the JOURNAL come. Success to it.

H. M. WILLIAMS, M. D.

Bowdon, Ga., Aug. 1, 1883.

Bee and Honey Show.

Our Inter-State Fair opens at St. Joseph, Mo., Sept. 5, 1883. We expect a large attendance of bee-keepers, and we shall try to make it a good bee and honey show. I wish to say, through the BEE JOURNAL, that all bee-keepers, of any State, are invited to assist us in making a good display of honey, bees, queens, and bee-keepers' tools. Those who cannot come may send articles to me, and they will be exhibited. Our Fair will be good place to advertise bee-keepers' goods, (by exhibiting), as bee-keeping is on the increase. I shall not show anything in this department, for premiums, (being superintendent), but expect to exhibit at other Fairs, and I am willing to exhibit all books, papers, and other light articles, for others, if requested to do so, free of charge. Our bees have swarmed a great deal, and gathered some nice honey. We are having plenty of rain, and look for a good fall crop.

D. G. PARKER.

St. Joseph, Mo., Aug. 2, 1883.

A Word about Transferring.

Three or four years ago I had occasion to transfer 4 or 5 colonies of bees from box to frame hives, and not liking cutting up brood combs and fitting them in frames (having tried it once), I placed the box hives on the top of the frame hives, full of comb, or full of sheets of foundation. This can be done with any shape of a box, as I nailed strips or thin pieces of boards on or under the uncovered parts, making it bee-tight, except the

entrance to the lower hive. This forces the bees to pass through their new home. Now, if you do your part right, you will be delighted to see how soon the transferring will commence; they will begin to occupy it for all purposes, store room, dining room, bed room, excepting a parlor, which is out of date with my bees (I bought some of them from James Heddon). In a few days (say a week) I lift the box hive off and examine the lower hive; if they are well started, and you find the queen there, remove the box to a new stand only a few feet away, if you wish to unite the second drive with the first. For uniting keep moving the hives nearer together, a few inches each day, so that they will be close together by the appointed time, which will be 21 days, in this case, when your old combs will be ready to extract from and melt up, after driving out the bees. Mr. Heddon has given other particulars to be observed in transferring so thoroughly that I take much pleasure in referring any one interested in transferring bees, to his article on page 367.

W. HARMER.

Manistee, Mich., Aug. 3, 1883.

Poor Dry Season in Texas.

We are having a pretty dry season just now. Bees are working on cotton bloom and scattering wild flowers. I had 3 colonies to start with in the spring; have 8 now, all in good condition. I have not taken much honey this season.

M. C. GRANBERRY.

Austin, Texas, Aug. 6, 1883.

Unprecedented Honey Crop.

The honey flow here has been unprecedented and unlooked for. My best colony has given over 600 pounds of honey, up to date—over 100 pounds being comb honey, and I expect to get upwards of 700 pounds from it. The colony spoken of, carried in from 20 to 28 pounds of honey per day for nearly a week. I think there are upwards of 100,000 bees in the hive; it is a two-story one.

E. F. SMITH.

Smyrna, N. Y., Aug. 7, 1883.

No Honey Glut, this Year.

It is interesting to read the items in regard to the honey production of the country. I have fully come to the conclusion that we have not, and their will not be a honey glut this season. Some bee men in the best part of the honey flow hawked their honey around at a shilling a pound. They should not be in haste. This section won't glut the honey market. I think that I live in a great honey-producing State, and white clover was bountiful, and is our greatest and best honey-producing plant. Basswood came and went without giving us a smell. Buckwheat is splendid, averaging 4 feet high, and gives a perfect sea of bloom, but producing little honey. I say, do not be in haste.

JOHN GOCHENOUR.

Freeport, Ill., Aug. 6, 1883.

[The way to keep up prices, is to supply the market only as fast as it is needed.—ED.]

Sweet Clover Honey.

Bees doing well, but not as well as H. W. Garrett's, of Coeyman's Hollow, N. Y. I was there yesterday, and Mr. Garrett took me through his apiary to show to me his box honey, which was very fine, and from 30 to 60 pounds on almost every hive, ready to come off. It was enough to make any bee man wish for acres and acres of sweet clover, that being what they have obtained so much honey from. No bee-keeper can afford to be without sweet clover. My opinion is that bee-keepers will have to cultivate honey-producing plants if they expect to make the business pay.

A. SNYDER.

Clarksville, N. Y., July 25, 1883.

Not Half a Crop of Honey Here.

We have had, so far, not half a crop of honey; not one-half of my bees have swarmed, which showed that honey was not plenty. My 50 colonies hardly making a living for the last two weeks; if it should continue a few weeks longer, I shall have to give them back the surplus, to save them. There was no honey from basswood this year.

H. T. HARTMAN.

Freeport, Ill., Aug. 4, 1883.

Hoary Vervain.

I send you two blossoms and two leaves of a plant that grows here in pastures and low ground. Bumble bees and honey bees work on it from morning until night. Is it a good honey plant, and what is its name (common name?) Bees have done very well so far, and we think there will be a good flow of fall honey if we have some more rain.

J. F. SELLERS.

Reynolds, Ill., July 24, 1883.

[The plant is the Hoary Vervain, or *Verbena stricta*. We have several wild verbenas which, though in appearance very unlike the popular cultivated flower of that name, are, botanically, closely allied, and are all good honey producers.—T. J. BURRILL.]

Poor Crop of White Honey.

The white honey crop in this section, the season for which is just closed, is light, and the prospect for a crop of dark honey is poor, the weather is so wet and cold. However, we shall have a large bloom, and if it should clear off warm, in a few days, I shall get some honey.

EDWIN THEW.

Saranac, N. Y., Aug. 5, 1883.

Italians Working on Red Clover.

We have had a heavy honey dew on the yellow willow since the 2d inst. The white clover and catnip bloom was immense. Bees are doing pretty well. I saw quite a large number of Italian bees working very busy on red clover this morning. I have both hybrids and Italians.

S. D. MCKINLEY, M. D.

Melrose, Iowa, Aug. 7, 1883.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00, or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Do not send coins in a letter. It is dangerous and increases the postage unnecessarily. Always send postage stamps, for fractions of a dollar, and, if you can get them—one-cent stamps; if not, any denomination of postage stamps will do.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper, shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter, on your label, notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a statement of account every week.

May we ask you, dear reader, to speak a good word for the BEE JOURNAL to neighbors who keep bees, and send on at least one new subscription with your own? Our premium, "Bees and Honey," in cloth, for one new subscriber to the Weekly, or two for the Monthly, besides your own subscription to either edition, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

Bingham Smoker Corner.

Large Smokers need wide shields, Bingham's have them, and springs that do not rust and break, and bellows that sparks and smoke do not enter. The Conqueror has all improvements made to date, and a 3x7 inch stove, and 5x7 inch bellows. Sent post-paid for \$3.75. Address,

BINGHAM & HETHERINGTON,
Abronia, Mich.

CYPRIAN CONQUERED.—All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am "boss." Bingham's "Conqueror Smoker" did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham.

G. M. DOOLITTLE,
Borodino, N. Y.,
Aug. 15, 1883.

EXCELLING ALL.—Messrs. Bingham & Hetherington, Dear Sirs:—I am now selling your Smokers almost exclusively. You are excelling yourselves in smokers all the time.

Respectfully,
J. G. TAYLOR, Patented, 1878.
Austin, Texas, May 10, 1883.

THE VERY BEST.—The Bingham "Conqueror" Smoker is the very best thing I have tried in that line.
M. M. LINDSAY,
Fulton, Tenn., July 24, 1883.

During the following three months, Bingham Smokers will be sent post-paid, per mail, on receipt of the following prices:

The "Doctor" (wide shield)—3½ in. fire tube, \$2.00
The Conqueror (wide shield)—3 in. fire tube, 1.75
Large (wide shield)—2½ in. fire tube, 1.50
Extra (wide shield)—2 in. fire tube, 1.25
Plum (nar. shield)—2 in. fire tube, 1.00
Little Wonder (nar. shield)—1½ in. fire tube, .75
Bingham & Hetherington Uncapping Knife... 1.15

With thanks for letters of encouragement, and the absence of complaining ones, we tender to our thirty-five thousand patrons our best wishes.

Very Respectfully Yours,

BINGHAM & HETHERINGTON.
Abronia, Mich., June 1, 1883.

Special Notice.—We will, hereafter, supply the Weekly BEE JOURNAL for one year, and the seventh edition of Prof. Cook's Manual of the Apiary, bound in fine cloth, for \$2.75, or the Monthly Bee Journal, and the Manual in cloth for \$1.75. As this offer will soon be withdrawn, those who desire it should send for the book at once.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Sample Copies of the AMERICAN BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

The Original BINGHAM Bee Smoker

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$5 per 100.

COMB HONEY WANTED.

We are prepared to purchase large lots of Fancy COMB HONEY in 1 and 2 lb. sections, or Harbison frames, for which we will pay an advance of 5 cts per pound over New York prices. CASH ON DELIVERY in sound condition in London; the price of extracted honey will be paid for all broken combs. This is an excellent opportunity for bee-keepers wishing to visit Europe. Correspondence solicited. **W. M. HOGE & CO.,**
The Apiary, Leconfield, Rd. N.,
33ABit LONDON, ENGLAND.

BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS C. NEWMAN.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

Mrs. J. F. Upton gives the following notice of this book in the Bath, Maine, *Sentinel*:

A guide to the management of the apiary for profit and pleasure, by Thomas G. Newman. This work is designed to initiate beginners in bee-keeping in all the secrets of successful bee-culture. Beginning with the different races of bees, the author takes his readers along step by step, carefully explaining the different kinds of bees, illustrating each kind with the eggs and brood, explaining the terms used, the production of wax and comb, and the work done by these wonderful insects. The establishment of an apiary is next considered; the best location, time to commence, how many colonies to begin with, what kind of bees to get, how to care for a first colony, keeping bees on shares, changing the location, all of which it is indispensable for a beginner to know. It is also important to know which kind of hive is the best, how to procure the best comb honey, how to procure it for market, how it should be marketed, what to do with candied comb honey, and how to extract honey. The scientific management of an apiary is then entered into, and illustrations of all the necessary appliances introduced. There is a chapter devoted to the honey extractor and its use, and another to comb foundation and its use. The various honey-producing plants and trees are named and illustrated. Various methods for exhibiting bees and honey at county and state fairs are described. The best and safest plans for wintering bees are discussed, the book closing with some general advice to beginners. The author says of his book on Bees and Honey, "it was not designed to supersede or supplant any of the valuable works on apiculture already published, but to supply a want for a cheap work for the beginners." We most cordially recommend this work not only to beginners, who will find it invaluable, but to all who are not already familiar with the lives and movements of these industrious and intelligent little workers. The information to be gained as to their habits, manner of breeding, intelligence, energy and wonderful instincts, by reading this book alone, is enough to make one regard the bee with admiration and amazement.

PRICE—Bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Canada Thistles for Honey.

Dr. J. C. Thom, of Streetsville, Ontario, has written to the *Canadian Farmer*, wondering why the Canada thistles should not be mentioned in the newest bee books among the honey-producers. It has often been mentioned in the BEE JOURNAL as such, but as it is an objectionable pest, and should not be encouraged, even if it is a good honey-producer. The Doctor says:

I can only account for the omission of any notice in these works of a very important source of honey in Canada by the supposition that it is rare in the United States. As the States of Michigan and New York are our immediate neighbors, I am at a loss to understand why it has not yet crossed the borders and taken the oath of allegiance, it being essentially aggressive, migratory and tenacious in its characteristics. It is now naturalized over the large extent of country, extending from Quebec to Sarnia. Its flowering season extends from the latter end of June to the same time in August. It may be fairly relied upon for a continuous flow of honey. It ranks, in my estimation, scarcely second to clover and basswood.

During the season of 1882, when all other sources of honey seemed to fail in this region (even clover and basswood), the thistle came to the rescue of 100 starving colonies in my apiary, and in the space of 15 days they had accumulated from that source alone sufficient winter stores. The present season, with an abundant flow from clover, and a partial one from basswood, the thistle has as usual made its delicious aroma perceptible in the extractor, making glad the hearts of bee-keepers. The honey from this source is rather thinner than that from clover, clear, not inclined to granulate, of a delicious flavor and

aroma, only to be recognized by those who have passed through fields of ripening grain purple with thistle heads nodding to the breeze.

Beeswax.—Concerning the boiling of beeswax and preparing it for the market, an exchange remarks as follows:

It is found that the larger the cakes of wax are the better it keeps, and the higher price it brings. Also, that the more gently it has been boiled, the better it likewise is; for too hasty boiling renders it hard, and this increases the difficulty in bleaching it.

The Premium List of the Maine State Agricultural Society is received. It shows premiums amounting to \$60 on bees and honey. Any one interested can get a premium list by sending to Mr. A. L. Dennison, Sec., Portland, Maine; or to Mr. Horace B. Cony, Augusta, Maine, who writes us as follows: "While our premiums are small compared with other States, still it is something, and if bee-keepers will attend and exhibit, we can do better hereafter. This is our first attempt, so we could not expect much."

Ontario Convention.

The third annual general meeting of the Ontario Bee-Keepers' Association will meet in the City Hall, Toronto, on Tuesday, the 20th day of September next, during the second week of the Industrial Exhibition. As the North American Bee Keepers' Convention meets at the same time and place, it has been arranged that the two bodies hold joint meetings in discussing matters pertaining to our common interests, as the leading bee-keepers of America are to be present. This will, undoubtedly, be the most interesting meeting of apiarists ever assembled in Canada. The venerable Mr. Langstroth and all the prominent bee-men of the United States are expected to be present. A profitable time is anticipated, and a good turnout requested. The convention will last three days. A meeting for the purely business work of our associa-

tion will be held sometime during the convention, of which due notice will be given.

R. McKnight,
Pres. Ontario Bee Association.

Preparing Bees for Winter.

In the *American Agriculturist* for September, Prof. Cook writes thus:

The apiarist should prepare his bees for winter as soon as the frost makes all farther gathering of honey impossible. Examination will show whether there is sufficient honey stored to winter the bees. If the frames, just as they are taken from the hives, containing bees, honey and comb, weigh 30 pounds in the aggregate, then there is enough honey. If not, good thick honey, or thick syrup, made by dissolving granulated sugar, should be fed at once, so that all cells may be capped over before the cold days of October check the labors of the hive. It is best that the honey be so abundant in the frames that we need not give the bees all the frames used in summer. It is better to use not more than 7 or 8 Gallup or American frames, and not more than 5 or 6 Langstroth frames. These are confined by division-boards. It is best to carefully exclude pollen. Frames of pollen are set aside, to be returned when breeding is resumed the succeeding spring.

The bees may easily change the position of the cluster in the cold days of winter, and it is desirable to cut small holes the size of a thimble through the combs, an inch or two above the centre. Cover above the bees with sacks of dry sawdust, which should be long enough to reach over the division-boards and to the bottom of the hive. These protect the bees from the extremes of heat and cold, and promote healthfulness. Thus prepared, the bees to be wintered in chaff hives on their summer stands, will need no further care until the succeeding April. If the bees are placed in the cellar, they need not be touched again until just before winter comes, when they are to be taken in.

Mr. E. F. Smith, Smyrna, N. Y., writes: "I should have been more explicit about my report. The colony, and its increase, have given 761 pounds to date. My apiary report will soon be forthcoming, and will show more than an average of 200 pounds per colony."

Another Bee Paper Dead.

It is but a year ago that we chronicled the death of the *Bee-Keepers' Instructor*, which died for the want of sufficient support; now the *Bee-Keepers' Exchange* has died from the same cause. The *Bee and Poultry Magazine* of New York City will fill out the unexpired subscriptions, and thus none of its subscribers will suffer pecuniary loss. Mr. T. O. Peet, the late editor of the *Exchange*, in the *Bee and Poultry Magazine* for August, says:

We remember writing, when the *Instructor* collapsed, that it was, perhaps, a victim to the law of the "survival of the fittest," and made our brags that the *Exchange* still lived. We did not think then that ere a year had elapsed we should be writing the obituary of the "*Exchange*," but so it is, and it corroborates the fact that we know very little of the future, and should be very careful how we talk and presume upon it.

"One comes and another goes." During the past year two bee papers have ceased to exist, but still the number remains the same as then, for two more have been born during that time—the *Apiarist* in Maine, and the *Apiculturist* in Massachusetts.

For some years there has been a mania for starting bee papers, which live but a few months or years, and then die for want of support. Which one is next to succumb, we know not, but we expect "the survival of the fittest."

The two that have lately died were selected to receive the support of the "co-operatives;" whether this was "the last straw that broke the camel's back," we do not know, but certain it is that they gave up the ghost in rapid succession. We learn that the co-operatives are casting around to make another selection for their organ—but it will be wisdom for the papers so approached to beware, and profit by the fate of those that have preceded them as organs of discontent. Bee-keepers generally have no relish for such elements of discord, and will surely stamp their disapprobation by withdrawing their support from papers that encourage discord and malevolence.

It will be far better not only for their personal comfort, but also for the public good—if these men will cease their efforts to set the bee-keepers of the East and West at variance, and unite heartily in every good work to extend the usefulness of the bee periodicals now existing,

and join in the bonds of unity the bee-keepers of the entire country, and thus aid the advancement of apiculture every where—for unity is strength; division is death.

Good.—The Fremont, Mich., *Indicator*, of Aug. 9, says:

George Hilton has taken 1,833 pounds of surplus honey up to Aug. 4, from his 35 colonies of bees, spring count. He says, judging from the amount now on hand, that they will double the amount before the season closes. His apiary now contains 58 colonies.

On Aug. 11, Mr. Hilton wrote us as follows: "I have to-day taken 383 pounds more of as fine comb honey as I ever saw, making 2,216 pounds up to date. Bees are still doing something on white clover. Our fall flow has not commenced yet."

Trial Trip—25 Cents.

As the season for Fairs has arrived, and wishing to be able to reach several thousands of the old-fashioned bee-men, and by the aid of the *BEE JOURNAL* to lift them up to higher ground, adopting newer methods and progressive ideas, we make the following very liberal offer: We will send the *Weekly BEE JOURNAL* three months on trial, for 25 cents. In order to pay for getting up Clubs, we will give a copy of Fisher's Grain Tables, or Scribner's Lumber and Log Book, to any one who will send us five trial subscriptions (with \$1.25); for a club of ten we will give a cloth copy of *Bees and Honey*; for a club of 15, a cloth copy of the 7th edition of Cook's Manual of the Apiary; for a club of 25, we will present both the Manual and *Bees and Honey*. If any one wants these Books for nothing, here is an excellent opportunity to get them for a little exertion.

The Mendota Union Fair will be held at Mendota, Ill., Sept. 3, 4, 5, 6, 7 and 8th, 1883. In the department for the apiary we notice the following premiums, Mr. H. W. Wixom being Superintendent:

Best and greatest display of honey.....	\$5	\$3
Best sample of honey, not less than 5 lbs.	3	2
Best swarm of bees.....	3	1
Best bee hive for all purposes, combined.	2	1
Best display of bees, hives and surp. honey. Diploma		

Committee—M. S. Tinker, Mendota; Andrew Winters, Mendota; Jos. Lewis, Arlington.

Articles for publication must be written on a separate piece of paper from items of business.

Bee Convention at Toledo, O.

The next annual meeting of the Tri-State Bee-Keepers' Association will be held on the 12, 13 and 14 of next Sept., during the week of the Tri-State Fair at Toledo, Ohio. It is customary to say that Messrs. So and So, "and other prominent bee men will be present," etc., etc. Well, we have quite a number of "prominent bee men" (prominent at home) in this region, and they know how to raise the bees, get the honey, cure foul brood, and winter the bees too; but if Mr. Heddon is well enough to be at the meeting and the fair, we will pump him on wintering, and Mr. Muth on foul brood, and Novice, if here, on general principles, and the editor of the *BEE JOURNAL* to fill in where the rest lack. We do not expect to have any long essays or speeches. It being the week of the fair, we expect the great attraction for bee-keepers will be the Bee and Honey Show, and such bee-keepers and their friends as desire to stay several days can bring their "eatables" and blankets with them, and camp on the fair grounds. One or more tents will be provided for such as make application to me a few days before the fair, at a cost that will pay for the use of the tents, but we hope to be able to borrow tents and so save expense.

A premium is offered for the foundation machine making the best foundation for the brood-chamber on the grounds, and two mills have already arrived for that purpose, and the makers of three other machines have promised to be here if possible.

A premium list with entry blank rules and regulations, railroad fares, and freight rates, etc., will be sent free to all applicants.

DR. A. B. MASON.

Wagon Works, Ohio.

The new two-cent postage stamp is to be of a metallic red color, with a vignette of Washington. It will supersede the present three-cent stamp on the 1st of October.

Fall Catalogues.—We have received Catalogues of Strawberry Plants, etc., for the autumn of 1883, from R. H. Haines, Moorestown, N. J., and Ellwanger & Barry, Rochester, N. Y.

Fairs.—To any one exhibiting at Fairs, we will send samples of the *BEE JOURNAL* and a colored Poster, to aid in getting up a club. The Premiums we offer will pay them for so doing. For a club of 8 subscribers to the Monthly *BEE JOURNAL*, or 4 Weekly, we will present Dzierzon's Rational Bee-Keeping, price \$2.00.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

A Clergyman's Success with Bees.

The Iowa City *Republican* has a long article concerning the apiary and management of the Rev. O. Clute, in that city, from which we extract the following:

Our townsman, Rev. O. Clute, has for several years made bee-keeping a recreation. Many gentlemen get relaxation and amusement with the horse, the gun, or the fishing-rod. Mr. Clute gets it among his bees. And in his case the pleasure brings profit also, for he makes bee-keeping a financial success.

A year ago he began the season with 110 colonies of bees, 80 in his apiary, and 30 in charge of Mr. Ed. Younkin on College Hill. The spring and early summer, last year, were most unfavorable for bees. The weather was cold and the rain was excessive, but by daily feeding he kept his bees rearing large quantities of brood, so that they were very strong in bees. After the middle of June the weather became favorable, and the white clover bloomed in great profusion. The constant rains of spring and early summer had saturated the ground so that the clover remained in bloom a long time. It yielded honey well; and the linden or basswood also yielded well. From these two sources an excellent harvest was secured.

In favorable seasons there is a good flow of honey here from the fall flowers, including asters, golden-rod, figwort, boneset, sunflowers, Spanish-needle, heart's-ease, and some others. In this locality heart's-ease is found in large quantities. Last fall it seemed especially abundant. The frost held off until late, so that the season was long. The clover, the linden, and the fall flowers combined, gave a splendid honey yield. When the season was over, the crop from the 110 colonies was found to be a little over 17,000 pounds, an average of 154 pounds per colony, spring count. In addition to this yield of honey, the stock of bees was nearly doubled.

A part of this excellent success was due to the good management given by Mr. Ed. Younkin to the 30 colonies in his care. From these he obtained more than 6,000 pounds of honey, a little more than 200 pounds per colony. He doubled the stock of bees also. Mr. Younkin had for his share one-half of the honey and one-half of the increase of bees, which gave him a very good return for his summer's work.

Mr. Clute manages his apiary mainly for extracted honey, which he thinks is more profitable in this locality than comb honey. Not nearly so many pounds of comb honey can be obtained per hive, and it is more difficult to store it after taken from the hives, to prepare it for market, and to send it to market in good condition. The extracted honey is simply thrown out of the combs, run from the extractor directly into nice kegs or barrels, bunged up, rolled into the store room, and gives no further

trouble. When time for marketing comes, it can be weighed, loaded on a dray, sent to the railroad station, and go thence around the world with no loss for broken combs and mused honey.

Within a few years the production of extracted honey and the demand for it have assumed large proportions. It can never supersede comb honey, for the latter has excellence and beauty which will always be in demand. But the demand for extracted honey will, in a few years, be immensely greater than it is now. People are learning that it is a delicious, healthful, and cheap article of food, and are beginning to use it in place of the inferior and unhealthy syrups with which the market has of late years been flooded.

Visit to a Scientific Apiary.

The Bloomington *Pentagraph* of the 9th inst., contains the following account of a visit to Mr. H. W. Funk's apiary:

A party of bee-keepers, about 15 in number, left Bloomington about 8:30 a. m. yesterday for a visit to the apiary of H. W. Funk, 9 miles northwest of Bloomington. Arriving about 10 o'clock, they met a cordial reception from Mr. and Mrs. Funk and their two daughters. The apiary consists of about 140 colonies of Italian bees. These are placed on a level plat of ground some 60 or 80 feet square, completely covered with sawdust, and as clean as a house floor. Not a sprig of grass is allowed to grow on the plat. The hives are all painted white and set in straight rows running north and south, each row covered with an awning high enough for a person to stand under it. Mr. Funk opened hive after hive, showing beautiful Italian queens. Some of them he values as high as \$20. A visit to his honey-house was the next in order, where the visitors saw some 6,000 or 7,000 pounds of nice honey, mostly comb honey in sections and extracted, in packages of from small sizes to barrels of 550 pounds; also a foundation press, large quantities of wax and every appliance required for an extensive apiary. They then visited the vineyard, about two acres, with a great variety of grapes, the vines looking splendidly, but some of the grapes blighted. Dinner was now announced. And such a dinner! The reporter will not attempt to describe it, but the company will bear him out in saying that there was nothing lacking in the substantial and delicacies of the season. The company then adjourned to the parlor and had a bee-keepers' meeting, at the close of which a committee was appointed to draft resolutions of thanks to the members of the family for their hospitality. But we must not omit the visit to the flower garden, where the guests saw an immense variety of flowers and a great variety of honey-producing plants. The last thing was sampling Mr. Funk's wine, but the reporter not being a good judge in

such matters, will not attempt a complete description. The visitors finally bade adieu to the family, with pleasant recollections.

Do not send coins in a letter. It is dangerous and increases the postage unnecessarily. Always send postage stamps, for fractions of a dollar, and, if you can get them—one-cent stamps; if not, any denomination of postage stamps will do.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL,
Monday, 10 a. m., Aug. 20, 1883.

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

Our prices, of late, for extracted honey, have been 75¢c. on arrival, and for choice comb honey 140¢15¢.

BEESWAX—Has been in fair supply, and sold at 30¢32¢, for good, on arrival. CHAS. F. MUTH.

NEW YORK.

HONEY—We take pleasure in quoting the following prices on honey, obtainable in our market: Fancy white clover, 1 lb. sections (no glass) 26¢21¢; fancy white clover, 2 lb. sections (glassed) 16¢21¢; fair white clover, 1 and 2 lb. sections (glassed) 16¢17¢; fancy buckwheat, 1 lb. sections (no glass) 15¢; fancy buckwheat, 2 lb. sections (glassed) 13¢14¢; ordinary buckwheat, 1 and 2 lb. sections (glassed) 11¢13¢; extracted clover honey in kegs or barrels 26¢10¢; extracted buckwheat honey in kegs or barrels 7¢8¢.

BEESWAX—Prime yellow beeswax 31¢33¢.
H. K. & F. B. THURMER & CO.

CHICAGO.

HONEY—There has been a marked increase in sales this week of comb honey. New crop, prime 1 lb. frames (pure white) have sold at 30¢ when in fancy cases, in a small way; good many sales at 18¢, for some grade 1½ to 2 lb. frames (or prize package) when well-filled and white, 16¢17¢; not quite so well filled, 15¢.

Extracted is still slow, but late receipts have been ripier, and there is more inquiry; 9¢10¢. For choice clover; dark and buckwheat, 7¢8¢.

BEESWAX—30¢35¢, for prime to pure yellow.
R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—A dry North wind in May made our honey crop short in the Southern counties, and of a crop is a full estimate for California. Not much arriving, and the small amount coming forward is mostly medium quality. For extra white, either comb or extracted, the market is firm. White to extra white comb 16¢20¢; dark to good 10¢13¢; extracted, choice to extra white 7¢9¢; dark and candied 6¢6½¢.

BEESWAX—Wholesale 27¢28¢.
STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—New, in liberal offering, but little sold in quantities—held higher; extracted or strained at 7¢8¢, and comb at 16¢. Lots in fancy packages bring more in a small way, while old and inferior sells less.

BEESWAX—Inactive and easy, at 27¢28¢.
W. T. ANDERSON & Co., 104 N. 3d Street.

CLEVELAND.

HONEY—New honey continues in good demand at 18¢19¢, for choice 1 lb. sections, and such are readily placed as fast as received; 2 lbs. not so active, at 10¢12¢. Second quality sells 14¢17¢. Extracted not in demand.

BEESWAX—None in Market.
A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—We have had a shipment the past week from J. E. Crame, and a good sized shipment from I. V. Caldwell, of Cambridge, Ill., whose honey we had last year.

We quote our market prices, as follows: White clover, one lb. combs 20¢22¢; white clover, 2 lb. combs 18¢20¢; extracted, 9¢10¢.

BEESWAX—Our supply is gone; we have none to quote.
CROCKER & BLAKE, 57 Chatham Street.

CORRESPONDENCE

For the American Bee Journal.

My Method of Introducing Queens.

G. M. DOOLITTLE.

By referring to page 344, the reader will see how I made my nuclei by placing a frame of hatching brood in a wire cloth cage, so made that it would hang in a hive like a frame. After the cage had been left in the hive 5 or 6 days it was found well filled with young bees, which would always stay when put. Then by placing a queen-cell nearly ready to hatch in the cage at the same time, with the frame of hatching brood, this nucleus would have a queen 4 or 5 days old when the nucleus was formed.

This was as far as I had got at that time, but the next trial proved that I had not yet found out all the good points of my cage. About this time I made a queen nursery according to the description given in Alley's book, and had therein several young queens three days old. By the way, the Alley nursery is the nicest of anything of the kind I ever saw, and is well worth several times the cost of the book to any one who desires to rear from 50 to 100 queens. As soon as your cells are sealed, they can be placed in the nursery, and the queens kept until you wish to use them, by simply picking the nursery in any hive having sufficient bees in it to keep up the desired warmth.

But to return: At this time, as I placed frames of hatching brood in my cages, I let one of those young queens three days old run into the cage. In 6 days the frames and cages were taken out of the hive in which they were placed, and put in hives where I wished my nucleus to stand, by withdrawing the frame from the cage and hanging it in the hive. This was done near sunset, so but few bees would take wing, for I find that if done in the middle of the day, one-half or more of the bees will fly while the frame is being lifted from the cage, they are so anxious to get at liberty. This causes them to take their markings at other places besides the entrance, which makes quite a confusion before they find their way into the hive through the entrance. The next day all these queens went on their bridal trip, and in two days more were laying. Thus I had a laying queen in each nucleus in three days after forming them.

Soon after this I received a choice queen from a distance, which I did not want to lose, so I went and got a frame of hatching brood, put it in one of the cages, turned my queen and her attendants into the cage, hung it in a hive, and left it for five days. Upon getting it at that time, I found the cage well crowded with bees, and the cells, wherever the bees had hatched, were filled with eggs. I now placed a hive where I wanted it

to stand, put the frame, bees, and all in it, together with a frame of honey, and drew up the division-board. In three days I gave it another frame of hatching brood, and in a week two more, when I had a colony ready for anything in a short time after. Here at least we have one plan by which any queen can be safely introduced at any time when there is brood in the hive; and the beauty of it is, that the merest novice can do it and know no failure. Repetitions of the above have been equally successful, so I know whereof I affirm.

Borodino, N. Y.

For the American Bee Journal.

Dysentery, its Cause and Cure.

A. L. KEAR.

No satisfactory explanation has been given by any one on the much-discussed question of bee dysentery. Theories are advanced and experiments explode the same, and each year brings with spring the report of great mortality among bees; and yet if we deduce from this and that theory we may learn, we trust soon, the cause and cure of the disease.

In addition to what has been said, I will give my experience, this spring, with dysentery in making up a nucleus in the latter part of May, from which something may be learned on the subject.

Being in a hurry on making up nuclei, to save some valuable queen cells, I put 2 frames of brood, with the usual amount of bees, into a hive from which I had in March taken a queen-less colony of bees, which spotted the hive, showing unmistakable signs of dysentery. The combs were all taken out in March, but the usual refuse was left in the hive. I closed the bees in the hive, as usual, in making up nuclei, until dusk, when I opened it and found that the bees had spotted the hive, the same as the bees did in March. The next morning the bodies of the bees were swollen, and the bees were in a stupor. I then proceeded to cleanse the hive, and found the refuse to be very offensive. After the hive was cleaned out, the bees soon commenced to move about more briskly, and a normal condition was soon assumed.

From the above, and numerous other experiments, I am of the opinion that the greatest trouble lies in the refuse on the bottom-board of the hives. We are asked why it is that two hives exactly alike should be differently affected, under the same treatment? It is certainly easily explained; one colony may so cluster that the refuse may fall in a part of the hive that is poorly ventilated, and therefore become very poisonous by the damp accumulation of the same; the other may drop the same in a dry part of the hive, and produce no bad results. And again, any one who will take the trouble to observe, that colonies with pollen in excess, after wintering, will find the refuse having a bad smell, being worse than in case of less pollen, hence the refuse assumes

a more offensive form, if it is wet. I am of the opinion that if we could cleanse the bottom-board without disturbing the bees, during the winter, we would not have any cause for dysentery, or so manage the bees that the refuse would be dry, the same result would be attained.

For some years past I have not had dysentery in my apiary, and this spring only in a very limited way, having carried all of my bees through (92 colonies) in sawdust hives, made porous, so as to be as dry as possible and yet warm. I made my hives from plasterer's laths (no patent) and covered the bees over with sawdust. Bees have done but very moderately here, this spring. We had too much rain. It rained 26 days in June; that is, it rained some time in every 24 hours, for 26 days, during the month. Pana, Ill., Aug. 8, 1883.

For the American Bee Journal.

Many Fertile Workers in a Hive.

B. F. CARROLL.

In reading the questions and answers in the "What and How" department of the BEE JOURNAL, I see some one wants to know why there are such a variety in drones in a colony of a mated pure Italian queen. I do not remember Mr. Heddon's reply, but I am satisfied I have found out the "why" long since, and I now have a colony of pure Cyprians that have a very fine young queen in it, and there are not less than 100 laying workers in there, too, and had been there a long time before I gave them a queen cell. I have seen 20 or more workers laying as regularly as if they were laying queens, but it takes them a little longer to perform the operation. I have seen them, after laying an egg in a drone cell, try to turn around in the cell, and often they would bend back their wings against their head. Now, what I want to say is this: I have long claimed that any bees (workers) are capable of laying eggs, and I earnestly believe a goodly portion of the drones in all hives are from the eggs of workers. The idea advanced by some that a fertile worker is a bee raised near queen cells, and received a portion of royal jelly cannot be true, for in the above mentioned colony, I believe over 1,000 bees were laying eggs; queen cells started would have 10 and as high as 16 eggs; drone cells would have 3 to 10; worker cells the same. I have watched this colony for an hour at a time, and the bees would lay while I held the comb in my hands, and would pay but little attention to me. I would open the hive several times per day, using no smoker, raise a comb and hold it up before my face and the bees would always be busy laying eggs, attending to the young larvae, and would seem too busy to notice me. I have seen this before, and have introduced laying queens to these fertile worker colonies, and I am satisfied that the bees would continue to lay drone eggs while the queen would be busy laying worker

eggs, and this is why I came to doubt the "Dzierzon drone theory." That is, "a pure queen mated will produce pure drones;" it may be true, but the colony containing this queen will not have all pure drones, if any.

I wish Mr. Heddon, or some able bee master, could have had this colony to have made observations from, for the benefit of us more illiterate bee-keepers. It seemed from the color of the bees that appeared to do the most of the laying, that they were bees not over three weeks old. I could not find one of those old, shiny, black-tail fellows at the egg business.

Our honey flow that promised us a good thing about the middle of July from the cotton bloom, is over on account of drouth; not a particle of rain have we had since June 12 until to-day, when we had a good rain; the thermometer averages from 96° to 104° in the shade. The cotton plant, and every other green plant, had about *petered out*.

Dresden, Texas, Aug. 6, 1883.

For the American Bee Journal.

A Report for One Year.

W. H. STEWART.

I will now try to give a report of my bee-keeping for one year, beginning May 1, 1882, and ending May 1, 1883. As I have never before given a report in the BEE JOURNAL, it may, perhaps, be proper to preface this one with a mere hint as to the reason why my bees were all very weak in the spring of 1882.

I have always wintered my bees on the summer stands, until the last two winters. In the fall of 1880 I had 85 colonies in first-class condition. In the spring of 1881, I had but 14 left alive. I ran them through the summer for increase, and increased to 45, but they were all quite light and weak when I put them in the cellar. This explains why they were weak in the spring of 1882. As the weather was wet and cold in the spring of 1882, I was compelled to feed them regularly, and give them extra attention up to June 10.

I use a very simple hive, one that I would not like to exchange for any of the so-called standards. It is just a plain box of inch boards; top and bottom both movable; box 17x17 outside, and 13½ deep. I use 10 frames 12x12 inside measure; end-bars ¾x¾, and 12 inches long (these end-bars admit of strong nailing); top-bars ¾x¼ inches; bottom bars ½x¼ inches; the bottom bars being narrow, allow dead bees to fall down between the combs without cloying the spaces. The grooves on which I hang the frames are ⅝ deep; this gives ⅜ passage over the frames, both summer and winter. The space between the end bars of the frames and the sides of the hive is ⅝ inches; this allows the handling of such deep frames with perfect ease and without danger of crushing the bees, and I have never found comb built between the frames and the side of the hive. The space between the bottom bars of the frames

and the bottom board is ⅝ inches, which gives ample room for dead bees to be carried along on the bottom, towards the entrance, without cloying under the frames.

I use no division boards. I consider them worse than useless. I never give the bees but two combs more than they can cover, and I always chose to keep weak colonies in the back part of the hive. I find that they will build towards the entrance much more readily than they will build back. I hang the frames with the sides towards the entrance. Cold winds do not drive in between the combs as bad as when the ends of the combs are towards the entrance.

My way of feeding is to go after dark and lift off the top board; lift out the empty comb on the back side of the cluster and pour into it thin syrup, or honey thinned up with thin flour starch. I give only enough to last one or two days. I then hang the comb in again, put the cover carefully on, and pass on to the next hive. This work may be done after dark without smoke, as the bees will not leave the combs when they cannot well see to get home again. A lantern may be used if it is not held too near the bees. Robbers are more apt to make trouble if fresh feed is placed on the side of the cluster nearest the entrance of the hive.

I found on June 10, 1882, fresh clover honey in these feed combs, and from that time we had rather a good honey season. We extracted 1,000 pounds of white clover honey up to July 14; then came basswood bloom, and we extracted 2,000 pounds; then we took of buckwheat and other late honey 1,000 pounds; making 4,000 pounds in all.

I use the hives 2 stories high during honey season, and in the last week of August, the upper stories were nearly full of capped honey, and the lower stories were full of brood. I then divided the bees, making two colonies of each one; giving each colony (as near as I could) one-half of the brood that was below, and of the capped honey that was above.

The queenless colony had to rear a new queen, and it only gathered about what they consumed during the balance of the season. I put them in the cellar on Nov. 16, after dark. I do not use the bottom boards of my hives in the cellar. The top boards are made 17x17, the same width of the hive, and do not project over. I nail a cleat on each end to prevent warping. This cleat is 3 inches wide, and sets up edgewise, and is on top of the cover. I lay down some loose boards on the bottom of the cellar, and then lay a top board on the loose boards.

When these top boards are thus arranged all around the cellar, I set the hives on top of them, and then another tier on the top board cleats of this first row, and so build them up 4 or 5 hives deep. You will understand that each hive thus arranged has a bottom ventilation 3 inches deep and 15 inches wide, both front and rear of the hive, which, all counted, makes 90 square inches of bottom ventilation. How is that

compared with ½ inch blocks, Mr. Doolittle?

I give not a particle of upward ventilation. No quilts, no chaff, no enameled cloth, or any such fluneries, but just the naked smooth hive board, and it is nicely made to fit close. I calculate for the vapor from the breathing of the bees to condense on the top board and keep a constant supply of water for the bees. I can at any time go into the cellar (and I go about once a week) with a tallow candle (a lamp gives too strong a light) and look under each hive and up among the combs, and see the bees as bright and lively as in summer. I can use a wing, or even my hand, and reach clear across under each hive, and brush off all the dead bees that have fallen from the frames of one hive down on top of the next one below it without making any jar or disturbing the bees in the least.

I kept 85 colonies through this last hard winter in a cellar just large enough to contain them by building them 4 deep on each side, and 5 deep at the back end; and, in the spring, there was not more than 3 quarts of dead bees on the cellar bottom, and no dead bees or mold at all among the combs. All came out of the cellar March 10 (after dark) in first-class condition (except 2 nucleus that starved), and have done splendidly up to the present date.

On May 1, at the expiration of the year for which I am now reporting, the bees were in better condition than in the middle of June, 1882. My bees are Italians, hybrids and blacks, about an equal number of each kind, and I must say that the hybrids are by far the best workers; the blacks the best breeders; the Italians the best to keep out moths, and I think that one kind is just as good on a sting as the other, but I use no veil for either. The only great advantage that I am able to see in keeping the Italians is to get the hybrids.

How sweet this May morning, fruit trees all in bloom,
Prophecies of summer, and a harvest to come,
All nature is crowned with her floral banquet,
O'erflowing with nectar, this bright morn in May.

But what of the nectar, and what of the bloom?
What of the sheen of the May morning sun?
And what of the spring time; no harvest could come,
Of unfertilized flowers to gladden our home.

Then hie away bees, sweet treasures bring home,
Go, scatter the pollen, o'er petal and bloom,
Go, make sure of the promise of a harvest to come,
O, grand is the lesson we learn in thy hum.

Orion, Wis., May 20, 1883.

Frankford, Pa., Herald.

Robbing—Words of Caution.

JOHN SHALLCROSS.

Young bee-keepers will, in their early experience, be frequently required to call a halt, while they inquire into the nature or remedy for some existing trouble. A few days ago there came a sudden cessation of the honey supply. The dry weather, the hot sun and the advanced season, had deprived the white clover bloom of its nectar-secreting properties. The linden blossoms had yielded to the en-

croachments of the incipient fruit. The holyhock and the sun-flower had not yet sent their cards of invitation to the insect world, and the bees, in consequence, lounged idly in front of their hives waiting for something to turn up. Such a condition of affairs is always a season of anxious watchfulness to the apiarist, for

"Satan finds some mischief still
For idle hands to do."

And, when he has that kind of an enterprise in contemplation, the bee is an active and pliant instrumentality in his hands. Suddenly, in a certain locality in our neighborhood, the bees were in commotion. Something unusual had taken place. The strong colonies were raiding the weak ones and robbing their stores. Each colony seemed to be testing the courage of the neighboring colony, until every thing was in indistinguishable commotion. What could have started this tumult? The cause was soon ascertained.

A young man, utterly ignorant of the first principles of bee-keeping, had witnessed the transfer of a colony a few weeks previous, by an experienced manipulator. He had seen him cut away the superabundant honey and hand it over for family use, while the empty comb and the young brood were carefully fastened in the frames, and placed in the new hive for the use of the bees. The colony soon repaired damages, built additional combs, and the young man, supposing that he knew just how to get the profits out of that hive, proceeded to take the honey by cutting out the well-filled cells, throwing away the brood and empty comb as worthless, and leaving the yard well smeared with the spilled sweets. The bees were left to get back to the hive as best they could, and to prepare, as he supposed, for a similar onslaught a few weeks hence. In place of so doing, they swarmed in disgust, from their ruined home, clustered under the porch of the house, and indulged their stinging propensities with uncomfortable prodigality, until the practical man was sent for who, amid many unorthodox thoughts, subdued and re-hived them. In the mean time, the warm sun had carried the odor of the spilled honey into the air, and attracted the bees from several squares around. There was a grand carnival over this free lunch, and the revelry kept up until the last platter of the feast had been licked clean. The sudden failure of this bonanza left the bees wild with excitement. They were ready for any thing but honest labor, and into mischief they went, by robbing their more helpless neighbors. For a few days the bee-keepers were kept busy in correcting the trouble. Wire screens had to be placed over the entrances to the weak colonies, and the hives moved to other stands. Entrances to still stronger colonies had to be partly closed to enable the bees better to defend their treasures, which they did with good effect. Feeders were brought into requisition for the nuclei and marauders, who lingered late around the wire screens, were thoroughly syringed with cold water.

These remedies, actively administered, put a stop to the mischief, until some ignorant or careless fellow shall treat the bees to another unearned feast.

In this, there is a valuable lesson for the beginner. While the fields are yielding their stores of honey, bees will give strict attention to business, but when nothing is to be gathered, they are easily led into temptation. When once they have fairly entered upon a system of thieving, it is almost impossible to control them until many of the weak colonies have been hopelessly ruined. In working about the hives, in the times of scarcity, the young apiarist, and the old ones as well, should be provided with sponge and water to instantly wash up every drop of honey which may be spilled. Pieces of comb should be carefully picked up and carried away, and every thing be kept scrupulously clean. Hives should be opened as little as possible, and only toward evening, when the bees have gathered to their respective hives. Careful watchfulness should be observed to detect the first indications of stealing, and prompt means should be introduced to stop it. Feeding in the open air, in times of scarcity, or, in fact, at any time, is an exceedingly reprehensible practice, as it is sure, sooner or later, to lead to trouble. Remember, that bee-keeping requires the earnest application of well-matured common sense.

For the American Bee Journal.

Successful Honey Production.

J. M. SHUCK.

The main object for which bees are kept is to obtain honey. "Bee-keeping for profit," as that great gardener and florist, Peter Henderson, would say. Why do we desire a standard frame? Is it so that we may produce more honey? Or, is it that we may produce more bees, and, therefore, more honey? To the trial, bee-keepers; the proof of the pudding is in the eating, not in theories as to whether that pudding is round, square, shallow, deep, tiered-up or stored at the sides.

Honey is the word that sweetens all the rest. Who has it, and who sells it, and who has the profits? Is it a lawyer, a doctor, a clerk, a writer of beautiful books, a teller of delightful stories, a lecturer, an editor, or a plain untitled producer of honey—a bee-keeper?

What hive does he use? What frame is provided to hold the combs for his myriads of workers? How many of these master producers do you know who annually make a large average production of honey? Ask them what frame they use in their bee yards. Do not ask, how they winter the bees, or whether they store at the sides or top, or underneath, but how much honey? Do not ask if he ever wrote a book, or contributes weekly or monthly to the papers, but how much honey? Ask if he is in the business, and has been for years; if he does no other business, and pro-

vides well for his family, and do not forget to ask how much honey.

Get the data, figure the result, make your hives, and be happy. We will never see a standard frame. We do not want it; the individuality of the bee-keeper crops out in his work oftener and larger, and he is happier in it, than any one else in any other calling. He would not be happy with a frame like everybody else. He would have it different, and if in no other way he would paint it red. Let him alone.

Des Moines, Iowa, Aug. 9, 1883.

Sweet Clover in Danger!!!

M. M. BALDRIDGE.

"A little learning is a dangerous thing." This is exemplified by the following item which recently appeared in a paper of very limited circulation published in this city:

"From all around us come complaints of the sweet clover which fills the highways and makes of itself an *unmitigated nuisance*. In the streets of St. Charles, and out upon the country roads, and in all the waste places, it grows heavy and rank, choking out grass and becoming an unsightly, tangled mass, through which it is almost impossible to push one's way. But for the travel along the roads, even the wagon tracks would be choked full! To be sure *it makes fine food for bees*, but there are plenty of honey-producing sources without it, and it is a mistaken idea to consider it a necessary part of our vegetation. Let the great nuisance be in some way abated."

The above makes a tip-top text for a lengthy and interesting article, but at present I will simply say that sweet clover, inasmuch as it "*makes fine food for bees*," may as well occupy "highways" and "waste places," as the worthless and "unsightly" *mayweed*! One way to abate the "great" and "unmitigated nuisance" would be to kill off the birds that feed upon and scatter the seed! Another way would be to stop the wagons and carriages from traveling the sides of the roads, in muddy weather, thereby picking up the seeds upon their wheels and distributing it for miles along the highway! I might suggest other ways to abate the "great nuisance," but at present the above must suffice.

While attending the Bee-Keepers' Convention in Chicago, last fall, I was under the impression that the legislature of Illinois had passed an act making it a *penal offense* to sow the seed of sweet clover, or to allow the plant to grow upon one's premises; that it was regarded and stigmatized as a noxious and dangerous weed, being classed with castor beans and Canada thistles! Being thus impressed, I thought it my duty to call special attention to the matter to the Convention, whereupon L. H. Scudder and the writer were appointed a committee to examine the special acts of the legislature to ascertain whether

that impression was correct or otherwise. After considerable time spent, as directed, the writer is pleased to report that he has not yet been able to find any mention whatever of sweet clover as a noxious or pernicious weed, and imagines that the enemies to this wonderful honey plant would have their hands full to make it appear, upon a proper investigation, that it really belongs to such a bad family. To conclude, it may be well for those interested in the growth and culture of sweet clover to keep a close watch of our legislators, pending their sessions at Springfield, that some one does not slip through an act that may give us more or less trouble in the future, for its enemies are already upon the war-path!

St. Charles, Ill.

For the American Bee Journal.

My Experiments in Wintering Bees.

H. S. HACKMAN.

The weather is once more warm, and the bees are again working on sweet clover, and also some are still at work on white clover. Bees commenced working on white clover on June 5, this season, and until then there was no honey laid up. The season was cool, with the exception of a few hot days; but bees have done well until the latter part of July, when it turned cool again for 10 or 12 days, but it has now become warm and dry, so that the bees are in good humor and gathering honey.

I started with 105 colonies on June 15, 1883; I had but a few natural swarms; I divided a few, and have now about 140 colonies. I have taken from 70 colonies 2,500 pounds of comb honey, and 180 gallons of extracted honey, all white clover. The balance, 35 colonies, have not yet filled their cases. So far, my Holy Lands, Italians and Cyprians are not doing much in storing surplus comb honey; it is the hybrids that are doing the business.

This has been, with me, a very busy season. I never knew that less than 500 colonies could keep me busy, but I found my mistake. I began winter with 230 colonies of bees packed in oak leaves, on their summer stands. Bees are in rows, east and west, 2 feet from centre to centre, and packed on the north side and between only; the south, fronting the sun, are open. The caps were nearly all filled with honey, except the one-story hives, and all were packed to the top, except that the one-story hives were packed over the top and all.

Now for the result: 125 colonies in one-story hives all died but 23 colonies; 105 in two-story hives were all alive but 5, although from the middle of April until the middle of June, I lost 18 more, mostly in two-story hives. What killed my bees in the one-story hives? and what saved them in the two-story hives? My hives are 12 inches deep, and 14x14 inches wide, and long entrance ($\frac{3}{8}$ x4 inches). By two-story, I mean two brood-chambers on top of one another,

Where I had two-story, both upper and lower entrances were open all the winter. In most cases the bees were clustered in the upper story; and I imagine the air space for the foul air to settle to, and the two entrances to circulate through and carry off the foul air, is what saved my bees.

The above conditions, as far as packing is concerned, was not always the same in the bees that lived. In at least one-third of the colonies, the surplus racks were left on; some empty, some partly filled, some with a flat cap, and cover the same as the one-story hives; so the upward ventilation was about the same in all cases, single or double story hives.

Much has been said and written on the wintering of bees; and what I have read, and what little experience I have had, I must say I am still lost for want of certainty, hoping, however, that the last winter's experience is worth something to me.

I was much pleased with Mr. Southwick's article on the best style of frame and hive. I think my success in wintering in the two-story hive, coincides with his ideas. Reason teaches us that bees can protect and reach their property and stores much better in a tall than a flat hive of the same capacity.

Peru, Ill., Aug. 12, 1883.

For the American Bee Journal.

Bees Removing Eggs.

DR. A. DREVAR.

DEAR EDITOR:—By the same mail that this will go by I send you an empty queen-cell, from which a very beautiful Italian queen hatched yesterday. My reason for sending it is, that it proves that bees do sometimes remove the egg from one cell to another. The eggs, which it was intended to raise queens from, were taken from a hive containing a beautiful queen which I got from Henry Alley, and placed according to his method in a hive from which all brood and eggs had been removed. Twenty eggs only were given in alternate cells, cut down to $\frac{1}{4}$ inch in depth. You will perceive by the peculiar broad and deep neck to this cell, that the bees added quite a quantity of wax to the strip of comb before commencing to build the cell proper. The cell is very large, and the queen which emerged from it, is also very large, though not larger than others which I have reared from the same mother.

I keep bees only on a small scale, to supply our own household with a pure sweet, and I believe honey is the only pure sweet which we can now get. The public, as well as the bee keepers, owe you a debt of gratitude for the stand you have taken against that fearful fraud, glucose, which has already sent many a man to his grave.

Although we are only a very small family (three), we manage to get away with about 500 pounds of honey in the year. We use it three times a day at the table, besides preserving apples, peaches and grapes with it. What we do not want to use, we sell

in quart glass cans at 15 cents per pound, and at that price I have found ready sale for all we have to spare.

Another thing I wish to remark: It has often been said in the bee books and journals that it does not pay the small bee-keeper to make his own foundation. There I quite differ, as I think nothing relating to the management of my bees has paid me better than the Pelham foundation mill. The great advantage of owning a mill is to have the foundation fresh, and when one wants it; that is impossible when trusting to dealers.

Our honey season here has been a good one, the yield from locust was immense; the white clover came in before the locust was done, and there are still a few flowers of it. The bees are now working on the Alsike, and I have noticed more bees on the red clover, this year, than ever before.

Annapolis, Md., Aug. 10, 1883.

The queen cell is as described, and the comb foundation good, for that made by plates.—[Ed.]

Translated from the Bienen Zeitung.

A Queen with Crippled Wings Impregnated.

REV. DR. DZIERZON.

"Is it not a contradiction or a retraction of your opinion, when you formerly made the assertion that a young queen could only be impregnated in the air, and consequently must be able to fly, and now to speak of the possibility of the fertilization of a queen which had left the cell with crippled wings?"

This thought might naturally occur to people, and such a remark be made in reading the heading of this article. In explanation of this apparent contradiction, I will relate to you my experience with a young queen last summer. In one of my queen-breeding boxes, a beautiful and strong Italian queen was hatched, which, on account of one of its left wings being considerably shorter than the corresponding right wing, was unable, in spite of all exertions, to rise up into the air, and immediately fell to the ground in an apparently perpendicular direction. I should not have hesitated to destroy her at once, if I had had another queen or a royal cell at my disposal; but this not being the case, I allowed her to remain in the hive. Two days later I examined the colony again, and tried the queen once more, thinking she might, in the meantime, have gained strength, and perhaps be able to fly; but the result was the same. The queen was, and evidently would remain, incapable of keeping on the wing. It then occurred to me that I might be able to restore the power of the flight to the queen by shortening the longer wing a little, in order to establish symmetry and the equilibrium.

This enabled the queen to keep on the wing for a short time, after which she again fell to the ground. But when I had clipped the wing still more, and made it almost like the

other, the queen was able, though evidently with very great exertion, to fly some distance in a horizontal direction until she had reached the hive, in front of which the experiments were made. I allowed her to enter, placing against the hive a shutter reaching to the entrance, and I waited to see what the result would be.

About noon on one of the following days, I noticed some excitement among the bees of a neighboring colony, and when I looked for the cause, I discovered the queen I had operated upon imprisoned by the bees, but fortunately she was unhurt. There can be no doubt she had been for her wedding trip, and on her return had missed the entrance of her own hive again, and a few days after she began to lay eggs, and proved to be normally fertile. Whether she had been impregnated on the occasion referred to, or during a subsequent excursion, it is, of course, impossible for me to say.

Would it not, after this, be possible to restore to a queen hatched with crippled wings, the power of flight by lengthening the shorter wing? Especially where the latter is very short indeed, instead of shortening the longer wing?

A solution of this problem does not appear to me impossible, and I would suggest, that a wing of another queen should be fixed by means of a well-adhering and quickly-drying glue or cement, to the stump of the crippled wing, which, of course, should not be too short.

The experiment might be worth trying by bee-keepers who are possessed of some very beautiful and strong Italian or Cyprian queens, which are unable to fly. I should be glad if bee-masters who consider themselves capable of performing such delicate operations, would attempt the experiment, and give us their experience, although very problematical, are incomparably greater than the reported impregnation of a young queen in a glass globe, or a cask with a hole at the top.

Kalsmarkt, Germany.

SELECTIONS FROM OUR LETTER BOX

When and How to Feed the Bees.

Extracted honey sells here, for home consumption, at 15 cents per pound, and granulated sugar can be bought for 10 cents per pound, and the Western bee-keepers say that sugar is better to winter bees on than honey. I mean to extract all the honey from the brood-chamber and feed sugar syrup. Which is the best time to extract and feed the sugar? The honey harvest winds up the last week in August, with the exception of some goldenrod and celandine; the latter has a bitter taste, and sometimes sour, which, we think, is bad honey to winter bees on. Would it be the right time to feed up the first week in September? That

month here is a mild one, but the nights are cool. About how much sugar to a 7-frame Langstroth hive, full of bees? What is the best way to feed, and how long to do the feeding? Please answer the above questions in the BEE JOURNAL.

HENRY TILLEY.

Castle Hill, Maine, Aug. 4, 1883.

[As soon as the honey harvest is over, you can safely feed sugar syrup for winter stores. In the evening is the best time (except when it is too cold for the bees to be out), so that it will all be taken away by the bees before the next day, for if it be exposed in the day time, robbing will be the result; on account of the absence of honey flora, the bees will eagerly search for any substitute, and become crazy over it. The bees will be better satisfied to have their winter stores capped before cold weather comes. For how to prepare the feed, see page 422.—ED.]

Giant Hyssop and Milk Weed.

I wintered safely 15 colonies and nuclei together in sawdust packing, and lost 3 by spring dwindling. I had 7 effective colonies to extract from at the beginning of the season; altogether 12 run for honey. I obtained 673 lbs. of extracted and about 50 lbs. of comb honey. My largest yield of honey from one colony was 226 lbs., and enough left for wintering. They are hybrids. We have had a remarkably good season, although old foggyism did not get much honey, on account of too much swarming and bad management. I have two honey plants for you to name. No. 1, with pink flower, blooms from the 1st of July, and is still blooming some; bees work well on it, and considerable of it is in our section of country, but, as to quality and quantity of honey, I know nothing. No. 2 is a rare thing here, but bees love to work on it wonderfully well; the time of blooming is about the same as the above specimen. The bloom is about gone.

E. M. COMBS.

Memphis, Ind., Aug. 1, 1883.

[No. 1, is Giant Hyssop (*Lophanthus nepetoides*), one of the Mint family, all of which have nectar of good quality. No. 2, Milk Weed (*Asclepias purpurascens*), allied to the milk weed, which kills bees by the sticky pollen masses.—T. J. BURRILL.]

Short Honey Crop.

The past spring was one of unusual cold, rain and wind, and I do not think that white clover ever promised better, but, after the first week's flow, it gradually slackened up. Mr. Doolittle says that the linden was on its last legs; it had no legs here to get upon. I have not, at this time, one-half as much honey from 32 colonies, spring count, as I had at this date last year from 22 colonies, spring

count. We have been suffering badly for the want of rain, but last week we were favored with a beautiful rain, though not half as much as we needed. Should everything be most favorable, our corn crop will only be a partial one, which will be the fourth successive light crop in this vicinity. Our hay crop is good; oats, good, and rye, fair. I doubt if there are 200 acres of wheat in two townships here; what little there was, was good. It is probable that I get more consolation out of a small corn crop than any of my neighbors, as I burn cobs in the smoker, and do not have to split them. Mr. Doolittle gives his method of forming a nuclei; and also tells of some one who has trouble with his. I will, at some future time, give the plan which I have practiced this summer with perfect success.

E. F. CASSELL.

Illinois City, Ill., Aug. 13, 1883.

Wood Sage.

Please give the name of the enclosed bloom and leaf, and state its merits as a honey plant. I never noticed it here until this season; there are lots of it in the low lands. It commenced to bloom July 10, and is 4 feet high. The bees pay strict attention to it all day long.

Kane, Ill.

R. M. OSBORN.

[American Germander, or Wood Sage (*Teucrium Canadense*). This is a very common plant in low, wet grounds, occurring throughout the Northern portions of the United States. It is another member of the Mint family, and, like its relatives, produces an abundance of excellent honey.—T. J. BURRILL.]

Legion of Queens in a Hive.

I see by the BEE JOURNAL of July 25, that Mr. Shirley found two queens in one hive. I am 13 on my slate. I have practiced returning the most of my swarms after the first issue, but before doing so I would "go through" the hive and remove all of the queen-cells in this hive. I took out 12 nice yellow queens, and left one to manage the affairs of the family. Can any one of the bee fraternity tell the cause of such a freak of bee nature? What does Mr. Heddon think?

H. B. HAMMON.

Bristolville, Ohio, Aug. 1, 1883.

A Bug—Water Boatman.

I send you a bug; please report its name.

W. THOUGHTEN.

Martinsville, Ill.

[The large bug is called by entomologists *Belostomatia grandis*, and sometimes is known by the common name of "water boatman." It lives in the water, feeding on living prey, but also dries through the air in search of other streams, ponds, etc., or to find company. It has a stout, sharp beak, capable of inflicting severe wounds.—T. J. BURRILL.]

My Experience with Sweet Clover.

I sowed it with Alsike and mammoth clover; they all bloomed this season; in the same range is timothy and blue grass. Calves, hogs and sheep (my stock rams) were allowed to run on it, and the hogs were fed. The mammoth and Alsike were eaten down close to the ground, while the sweet clover is from 4 to 6 feet high; nothing eating it. In case of the advice given to Mr. F. M. Cheney, to feed it down with pigs, it might be a benefit to bees, but it would be death to pigs. My stock eat rag and hog weeds in preference. I shall not sow any more of it, and will destroy what I have, if I can. I regard it as a weed useless only for bees, and a positive damage to the farmer and stock grower.

J. A. JOHNSTON.

Green Hill, Ind., Aug. 11, 1883.

[Your experience is very different to hundreds of others, who give the very opposite, as their experience. But we give all sides to every question, and all may strike a balance for themselves.—ED.]

Bees on a Strike.

Since the 27th day of last month the bees through this section have been on a strike, so to speak, when white clover gave out. It has been so very dry that other flowers have failed to yield nectar. Melilot clover is doing but little, and smartweed is, this year, a failure. Buckwheat is but little sown, so we may calculate but a small yield of honey for the balance of the season. Our corn, for this season, will scarcely produce half a crop, and fruit of all kinds is almost an entire failure.

H. W. WIXOM.

Mendota, Ill., Aug. 14, 1883.

That Glucose Slander on Bee Men.

It is but justice to the bee men of the world, that I add my testimony to that of Mr. Wm. Muth-Rasmussen, of California (page 377), against the foul slander upon the bee men of California, "that they feed glucose very largely, and make money out of it." Such a statement has not a particle of truth to back it. I spent six years in California, and did nothing else but care for bees and produce honey. In that time I have seen both sides of the bee business; I have seen the time when honey flowed as it flows in no other country; then I have seen many more seasons when there was scarcely any honey, and we had to feed the bees to keep them from starving, but we did not feed glucose; we did the same as Mr. Rasmussen; bought honey at a much larger figure than we had sold it for, and fed it to the bees. Such a base fabrication has its origin in the corrupt brain of the glucose manufacturer, and has no other foundation for truth than the satisfying of an unprincipled desire to steal the good name that pure honey has gained, by palming off their foul stuff upon the inexperienced; thereby making money for themselves, but aiming a deadly blow at the honest and hard-working

honey-producer. Mr. Editor, "tire not" in the good work you are engaged; in nor give the enemy any quarter until the popular verdict of an outraged people shall place the *heel of disapprobation* upon the head of this venomous reptile, *glucose*.

A. W. OSBURN.

Water Valley, N. Y., Aug. 3, 1883.

Little Increase and Surplus.

My bees (41 colonies) have not boomed any yet. I have had but little increase and very little surplus. I am out of the reach of basswood, and cannot make the seed grow. Sweet clover has also twice failed to grow for me, but I shall try again.

M. E. DARBY.

Dexter, Iowa, Aug. 13, 1883.

Honey Crop of New York.

Do not condemn the New York honey crop until you hear from more of us. The weather has been rather too wet, but bees here have done pretty well between showers. After rather a moderate yield from clover, basswood came in bloom, on July 19, and was very sweet for 18 days. From 40 weak colonies I have taken 3,000 pounds of very choice capped honey, with the extractor. Although I use a frame 11x13, I think Mr. Demaree is ahead in the frame argument.

W. H. S. GROUT.

Kennedy, N. Y., Aug. 13, 1883.

No Honey.

The honey season here has been the poorest I have ever known. No honey wave or honey shower came this way. Honey dew has made its appearance again this season in abundance.

H. R. BOARDMAN.

East Townsend, O., Aug. 13, 1883.

What the Bees Gathered in 30 Days.

The following is what an average colony of bees gathered from white clover, by weight, without swarming, on full frames of wired foundation, in 30 days: June 15, 1 lb.; 16, 2 lbs.; 17, 4 lbs.; 18, 5 lbs.; 19, nothing; 20, 3 lbs.; 21, 2 lbs.; 22, 3 lbs.; 23, 1 lb.; 24, 1 lb.; 25, nothing; 26, nothing; 27, 1 lb.; 28, 8 lbs.; 29, 9 lbs.; 30, 5 lbs.; July 1, 6 lbs.; 2, 3 lbs.; 3, 1 lb.; 4, 2 lbs.; 5, 5 lbs.; 6, 3 lbs.; 7, nothing; 8, 4 lbs.; 9, 10 lbs.; 10, 1 lb.; 11, 4 lbs.; 12, 3 lbs.; 13, 1 lb.; 14, nothing; 15, 1 lb.; total, 84 lbs. The above shows that not every day do the bees gather honey. In the height of the season, I only took on an average of 25 pounds from 40 colonies, to date, mostly in 13½ inch sections, or 7 to the foot. I use the Heddon case, and my honey is built in as good shape as when I used wide frames and tin separators, and I can empty a case of 28 sections in less time than it required to take out the 8 sections in one wide frame. I would almost as soon think of going back from a movable frame hive to the old box hive, as to go back from a case to wide frames and separators; they are relics of the past.

J. J. HURLBERT.

Lyndon, Ill., Aug. 5, 1883.

Horse Mint.

Enclosed I send a specimen of a plant that grows on old, worn-out, sandy land, and blooms in July. It yields considerable honey of fine quality. What is it? F. WILCOX.

Mauston, Wis., Aug. 3, 1883.

[Horse Mint (*Monarda Bradburiana*).

There are three other species of Horse Mint, all of which are good honey plants.—T. J. BURRILL.]

Vervain, Red Clover, etc.

Bees are doing well here this summer. There has been no honey drouth here at all. The fall flowers are coming in. Our bees are working very strongly on a plant which I have never seen mentioned in any publication I have ever read. This is the blue vervain (or vervine). I never saw them work on any thing any stronger, unless it is basswood. It seems to rival the spider plant, for they work on it all day, and I have seen a dozen on a single plant, and as quick as one bee leaves, another comes, and thus they keep at it all day. It grows in rich, moist land (not wet), along the creek bottoms. There are about 4 acres in this patch, and there are millions of bees on it. I would like to know if this has been recognized before as a honey plant? Will Italian bees gather honey from red clover? Or, will any strain of Italians or hybrids gather enough to depend on it for a crop of surplus honey? If any of them will do this, they will be the "coming bee" for this section, regardless of all else, for from June until September there is plenty of red clover.

AN AMATEUR.

Wayne Co., Ind., Aug. 14, 1883.

[Vervain has often been mentioned as an excellent honey producer. See pages 537, 540, and 569 of the BEE JOURNAL for last year. Occasionally bees gather honey from the red clover, but it cannot be "depended upon for a crop of surplus honey"—not by any means.—ED.]

Local Convention Directory.

1883.	Time and Place of Meeting.
Aug. 29.—S. W. Iowa, at Red Oak, Iowa.	It. C. Alkin, Sec.
Aug. 29.—Iowa Central, at Winterset Fair Grounds.	Z. G. Cooley, Sec. <i>Pro tem.</i>
Aug. 29, 30.—Ky. State at Louisville, Ky.	Dr. N. P. Allen, Sec., Smith's Grove, Ky.
Sept. 4.—N. W. Ill., & S. W. Wis., at Ridot, Ill.	Jonathan Stewart, Sec.
Sept. 12-14.—Tri-State, at Toledo, Ohio.	Dr. A. B. Mason, Sec., Wagon Works, O.
Sept. 18-20.—North American, at Toronto, Ont.	A. I. Root, Sec., Medina, O.

Oct.—Northern Ohio, at Norwalk, O.	S. F. Newman, Sec.
Dec. 5-6, Michigan State, at Flint.	H. D. Cutting, Sec., Clinton, Mich.

✎ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Feeding, Winter Passages, etc.

Please answer the following questions in the BEE JOURNAL:

1. With Italian bees is it necessary to feed at the close of the honey season to keep up brood-rearing?

2. How do you prepare winter food from sugar?

3. Do you make winter passages through the comb?

4. Do your bees, after swarming, fill the brood-chamber so that you have to extract to give the new queen room; or do you cut the queen-cells and introduce a new laying queen as soon as they swarm? Is not the latter the best method?

5. Do your hives front the south in winter as in summer?

6. Is it necessary to have a bottom ventilation? F. M. CHENEY.

South Sutton, N. H.

ANSWERS.—1. No; nor with any other bees in this locality. Late breeding is not valued by me as by some.

2. By boiling 10 pounds of sugar with 3 or 4 pounds of water (according to how warm the weather is when I feed), and adding one teaspoonful of cream of tartar, dissolved in water.

3. No, never; but over them with a bow.

4. After swarming the bees store more in the brood combs (as the pupae hatch out) than before, but as soon as the new queen begins to lay this honey will go into more bees, and the boxes above at a great rate. *No, sir*, I do not extract to give the queens room, nor cut queen-cells. I have learned better, and that, with proper fixtures and management, there is no necessity for so doing.

5. My hives front the east all the year around.

6. Only at the entrance, so far as I know.

Uniting Colonies.

I would like some information from Mr. Heddon. I have about 50 colonies of bees, and do not care about keeping so many, and as the country here is pretty well supplied, I could not get over \$5 or \$6, and as they are all in new Langstroth hives, and have ten frames of comb, I think I might make more by doubling them up, putting two colonies together and extracting from one. Our fall flowers are just beginning to bloom, and in a few days I expect my bees to be hard at work. When will be the best time for doubling them up? At present they are full of brood. Do you think it best to do it before they commence to work on the fall crop, or after it

has been harvested? Bees have not made any surplus here since the first part of June. We had a honey flow only about three weeks, which was very good, while it lasted, for those who were prepared for it.

A NOVICE.

Posey Co., Ind., Aug. 6, 1883.

ANSWER.—If you can get five or six dollars per colony for your bees in the fall, after the honey harvest is over, my advice would be run them as they are, getting all the surplus you can from your 50 colonies, and then sell one-half. If you want 25 colonies next spring, had you not better keep the whole fifty, for fear part might die? Then if they should, you would have your new Langstroth hives, combs, etc., without making or buying these supplies for the coming year.

I would much object to doubling them up for winter, after your fall harvest; for such colonies are more apt to have dysentery where there is no chance for them to void. Such doubling acts are a great auxilliary to the cause of dysentery in my apiary. But to double them before the fall harvest, is not so bad an idea. In case of such uniting, you can destroy all your poorest, and keep all your best queens. I would do the doubling and uniting at the commencement of the honey flow, not before, as Mr. Langstroth has told us all these operations with bees, work more successfully during a honey flow, than during a dearth.

Kentucky Bee and Honey Show.

The Kentucky State Bee-Keepers' Association will hold its annual meeting in Louisville, Ky., Aug. 29 and 30, at the Southern Exposition building. We hope to have a large attendance of the bee-keepers of the State, and also of other States, both North and South, as the convention will be in session during the week of the Honey and Bee Exhibit. And premiums amounting to \$60 are offered by the commissioners of agriculture of Kentucky, for Kentucky honey, and \$40 by the Exposition, for the finest Italian bees in Observatory hives. The premium on bees is open to the world, and we hope to see a fine display.

The Bee-Keepers' Convention and Honey and Bee Show will be held in the same week of the great exhibition of fruit, for which over \$2,000 in cash premiums will be paid.

We extend a cordial invitation to all bee-keepers' societies, to editors of bee publications, to honey-producers, and queen breeders, and all who are interested in apiculture, to be with us. We hope to have the father of modern bee-keeping with us, the Rev. L. L. Langstroth, to whom a cordial invitation has been given.

Reduced fair on all railroads, both North and South, will be offered to all who attend the Great Southern Exposition. It will doubtless be the grandest exposition ever held in the United States, in magnitude, and nearly equal to the Centennial.

N. P. ALLEN, Sec.

Notice to Iowa Bee-Keepers.

Quite a large number of bee-keepers in our State have expressed a desire for the formation of a State Association. A consultation with others has resulted in the decision not to attempt to hold a meeting during the coming State Fair, but if thought best to hold one during the time of the meeting of the State Agricultural Society at Des Moines next January. All bee-keepers who may be present at the Fair are earnestly requested to report to the Rev. O. Clute, at the Apianian Exhibit, on or before 1 p. m. of Tuesday, the 4th day of September, 1883, who will give them notice of a meeting for consultation, and also for the selection of a committee of arrangements if one is deemed necessary.

O. O. POPPLETON,

Vice-Pres. N. A. B. K. Society.
Williamstown, Iowa, Aug. 10, 1883.

Nebraska Bee and Honey Show.

I desire to call the attention of the members of the Nebraska State Bee-Keepers' Association, and all others engaged in apiculture, to the liberal premiums offered by the Nebraska State Agricultural Society in Class VII., entitled "Bees, honey and apianian goods," and especially the premium of \$25 offered for the best colony of bees. The test of colonies will be net gain, and will be weighed and sealed Aug. 28, and weighed again Sept. 11. Each colony must be the progeny of the queen and colony on trial. All shipments in this department can be made to the Hon. B. E. B. Kennedy, superintendent of Class VII.; and the bees should be on the ground on or before Aug. 27. All other articles may be entered, up to noon of Sept. 10.

M. L. TRESTER,

Sec. N. B. K. Association.
Greenwood, Neb.

The Northwestern Illinois, and Southwestern Wisconsin Bee-Keepers' Association, will hold its next meeting on Sept. 4, 1883, at John Swanzy's, 2 miles South of Ridot, Stephenson County, Ill. There will be facilities to take persons from the station to Mr. Swanzy's.

JONATHAN STEWART, Sec.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00, or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper, shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter, on your label, notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a statement of account every week.

May we ask you, dear reader, to speak a good word for the BEE JOURNAL to neighbors who keep bees, and send on at least one new subscription with your own? Our premium, "Bees and Honey," in cloth, for one new subscriber to the Weekly, or two for the Monthly, besides your own subscription to either edition, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS C. NEWMAN.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

Mrs. J. F. Upton gives the following notice of this book in the Bath, Maine, *Sentinel*:

A guide to the management of the apiary for profit and pleasure, by Thomas G. Newman. This work is designed to initiate beginners in bee-keeping in all the secrets of successful bee-culture. Beginning with the different races of bees, the author takes his readers along step by step, carefully explaining the different kinds of bees, illustrating each kind with the eggs and brood, explaining the terms used, the production of wax and comb, and the work done by these wonderful insects. The establishment of an apiary is next considered; the best location, time to commence, how many colonies to begin with, what kind of bees to get, how to care for a first colony, keeping bees on shares, changing the location, all of which it is indispensable for a beginner to know. It is also important to know which kind of hive is the best, how to procure the best comb honey, how to procure it for market, how it should be marketed, what to do with candied comb honey, and how to extract honey. The scientific management of an apiary is then entered into, and illustrations of all the necessary appliances introduced. There is a chapter devoted to the honey extractor and its use, and another to comb foundation and its use. The various honey-producing plants and trees are named and illustrated. Various methods for exhibiting bees and honey at county and state fairs are described. The best and safest plans for wintering bees are discussed, the book closing with some general advice to beginners. The author says of his book on Bees and Honey, "it was not designed to supersede or supplant any of the valuable works on apiculture already published, but to supply a want for a cheap work for the beginners." We most cordially recommend this work not only to beginners, who will find it invaluable, but to all who are not already familiar with the lives and movements of these industrious and intelligent little workers. The information to be gained as to their habits, manner of breeding, intelligence, energy and wonderful instincts, by reading this book alone, is enough to make one regard the bee with admiration and amazement.

PRICE—Bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

THOMAS G. NEWMAN,

925 W. Madison St., Chicago, Ill.

 A Liberal Discount to Dealers by the Dozen or Hundred.

Bingham Smoker Corner.

Large Smokers need wide shields. Bingham's have them, and springs that do not rust and break, and bellows that sparks and smoke do not enter. The Conqueror has all improvements made to date, and a 3x7 inch stove, and 5x7 inch bellows. Sent post-paid for \$1.75. Address,

BINGHAM & HETHERINGTON,
Abronia, Mich.

CYPRIAN CONQUERED.—All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am "pos." Bingham's "Conqueror Smoker" did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham.
G. M. DOOLITTLE,
Borodino, N. Y.,
Aug. 15, 1882.

EXCELLING ALL.—Messrs. Bingham & Hetherington, Dear Sirs:—I am now selling your Smokers almost exclusively. You are excelling yourselves in smokers all the time.

Respectfully,
J. G. TAYLOR, Patented, 1878.
Austin, Texas, May 10, 1883.

THE VERY BEST.—The Bingham "Conqueror" Smoker is the very best thing I have tried in this line.
M. M. LINDSAY.
Fulton, Tenn., July 24, 1883.

During the following three months, Bingham Smokers will be sent post-paid, per mail, on receipt of the following prices:

The "Doctor" (wide shield)—3½ in. fire tube, \$2.00
The Conqueror (wide shield)—3 in. fire tube, 1.75
Large (wide shield)—2½ in. fire tube, 1.50
Extra (wide shield)—2 in. fire tube, 1.25
Plain (nar. shield)—2 in. fire tube, 1.00
Little Wonder (nar. shield)—1½ in. fire tube, .65
Bingham & Hetherington Uncapping Knife, 1.15

With thanks for letters of encouragement, and the absence of complaining ones, we tender to our thirty-five thousand patrons our best wishes.
Very Respectfully Yours,

BINGHAM & HETHERINGTON,
Abronia, Mich., June 1, 1883.

The pamphlet "Honey, as Food and Medicine" is an excellent thing to give away at Fairs, where a good exhibit is made. A thousand copies will sell almost a fabulous quantity of honey, if judiciously given—say given to every one who buys a package of honey. Try it.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Sample Copies of the AMERICAN BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

Special Notice.—We will, hereafter, supply the Weekly BEE JOURNAL for one year, and the seventh edition of Prof. Cook's Manual of the Apiary, bound in fine cloth, for \$2.75, or the Monthly Bee Journal, and the Manual in cloth for \$1.75. As this offer will soon be withdrawn, those who desire it should send for the book at once.

The pamphlet, "Honey, as Food and Medicine," is in such demand, that we find it necessary to print them in still larger quantities, and can, therefore, still further reduce the price, as noted on page 285. Let them be scattered like "autumn leaves," and the result, we feel sure, will fully reward honey-producers for both the labor and the small expense.

Do not let your numbers of the BEE JOURNAL for 1883 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference

The new Postal Note will be obtainable in a few days at the Post-offices all over the country. Then any sum from one cent to five dollars can be sent in a letter, by obtaining a Postal Note, costing only 3 cents. After October 1, small sums can be easily sent to this office for 5 cents (3 cents for the Postal Note and 2 cents postage on the letter), and there will be no need of sending postage stamps in letters, which often get all stuck together by the damp weather, or being handled while perspiring.

The Waverley Novels.—T. B. Peterson & Brothers, 306 Chesnut Street, Philadelphia, Pa., have just commenced the publication of a new and cheap edition of "The Waverley Novels," by Sir Walter Scott, which will be completed in Twenty-six Weekly Volumes, each volume being a novel complete in itself, and one volume will be issued every Saturday until the whole are published. Each book will make a large octavo volume, have on it an Illustrated Cover, and will be sold at the low price of Fifteen Cents a volume, or Three Dollars will pay for the full and complete set of Twenty-six volumes.

40 TONS

OF COMB HONEY wanted; York State preferred. Say how much of each grade you will probably have, size of section, how soon it can be in shipping order (the whole or part of it), lowest cash price, and address F. I. SAGE, Wethersfield, Conn.

BEES Send to Chicago, Ill., for sample of AMERICAN BEE JOURNAL Monthly, \$1 a year. Weekly, \$2.

The Bee-Keeper's Guide; OR, MANUAL OF THE APIARY, By A. J. COOK,

Of Lansing, Professor of Entomology in the
State Agricultural College of Michigan.

320 Pages; 133 Fine Illustrations.

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

Read the following opinions of the Book;

All agree that it is the work of a master and of real value.—*L'Apiculteur*, Paris.

I think Cook's Manual is the best of our American works.—LEWIS T. COLBY.

It appears to have cut the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—J. P. WEST.

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—E. H. WYNKOOP.

This book is just what everyone interested in bees ought to have, and which, no one who notices it, will ever regret having purchased.—*Mich. Fur.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herold*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The richest reward awaits its author.—A. E. WENZEL.

My success has been so great as to almost astonish myself, and much of it is due to the clear, disinterested information contained in Cook's Manual.—WM. VAN ANTWERP, M. D.

It is the latest book on the bee, and treats of both the bee and hives, with their implements. It is of value to all bee-raisers.—*Ky. Live Stock Record*.

It is a credit to the author as well the publisher. I have never met with a work, either French or foreign, which I like so much.—L'ABBE DU BOIS, editor of the *Bulletin D'Apiculture*, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Paluski, N. Y.

We have perused with great pleasure this *code meum* of the bee-keeper. It is complete with the best information on everything belonging to apiculture. To all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee-man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound, and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor*.

EDITOR AND PROPRIETOR.

Creating Local Markets for Honey.

The California *Grocer* makes some comments on the suggestions we made sometime ago about scattering information about the uses of honey, and its value both as food and medicine, and while thoroughly endorsing the plan, it remarks as follows:

If it be acknowledged that an adoption of this means will be at all effective, why not make it generally so? If the suggestion of the BEE JOURNAL is worthy of adoption at all, it is worthy of being adopted to the fullest extent, as it is one of those propositions the remunerative quality of which is in exact ratio with the amount of energy and enterprise expended upon it. The information, published in an economical form, should accompany every sale, whether to wholesaler or retailer, in order that when the goods reach the consumer's market, the retailer might be enabled to send this information broadcast among his patrons to induce the purchase of this delicious household luxury.

The Indiana State Fair commences Sept. 21, and promises to excel all former ones. Bee-keepers should see to it that there is a large display of honey, both comb and extracted.

Mr. W. F. Clarke, Guelph, Ont., will attend the North American Bee-Keepers' Convention at Toronto, next month, and represent the BEE JOURNAL as well as make a report of the proceedings.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey at Fairs, will sell almost a fabulous quantity of it.

Caledonian Apiarian Society.

Mr. John D. Hutchinson, of Glasgow, Scotland, has sent us a short report of the Bee and Honey Show of Scotland, from which we extract as follows:

The tenth show of this society was held in a tent inside the showyard of the Highland Society. For various reasons it was not expected that the show would be a large one. The weather had been very much against the bees. Nearly all the exhibitors are from the southern portion of the country, and the existence of the society was only made known to some north-country persons yesterday, when they were told that bees were actually being shown. As a whole, the show, though small, was worth a visit. Among the most successful of the competitors is Mr. Angus Cameron, of Blair Athole, the winner of the Queen's Prize at the Wimbledon Rifle meetings in 1866 and 1869.

Considering the difficulties we have had to contend with this year, our show has been very successful both financially and otherwise. The bee-keepers are now getting their colonies removed to the "Heather," so with good weather (such as we have at present), I have no doubt but that we shall have a good harvest of heather honey. There has been little or no honey as yet, owing to the bad weather we have had. Everything connected with bee-keeping has been very quiet for sometime past.

Preserve the Wax.

Mrs. L. Harrison gives the following advice in the *Prairie Farmer*:

All hives containing honey, in which bees have died, should be fastened up securely so that no bees can enter, for if they are permitted to carry it off as soon as it is all gone they will try the strength of all weak colonies and many will be destroyed. We prefer to brush off the bees from combs and store them in a room, instead of fastening them in hives where they have no ventilation, as they become damp and moldy, and the pollen sours. We put our combs into clean hives and pile them one upon another in the honey house, where they are secure from bees, and will remain dry. It is not necessary to pick out dead bees from combs for,

the bees will do it, and work cheaper than we can if one comb at a time is given to a strong colony. Comb is a bee-keeper's stock in trade; better than money in the bank; and should be preserved, for while bees are building a pound of it they will store 20 pounds of honey. All bits of refuse comb should be made into wax, as it is very scarce at present, brings a good price, and is in demand for foundation.

Bee Tent for Fall Work.

The *American Agriculturist* remarks thus about the use of a bee tent for manipulating bees in the fall:

As is well known, bees become irritable if handled after gathering ceases in the autumn. To take out extra combs, extract the uncapped honey, and prepare for winter as directed above, is often the most dreaded work of the season. The bees seem cross at the failure to obtain labor, and cannot endure disturbance. By using a bee tent, made of wire gauze or mosquito netting, and large enough to set over the hive and operator, all this danger and trouble is avoided. The bees are apparently frightened into good behavior, and are as amiable as though in the midst of the honey harvest. The bee tent also prevents robbing, which is quite likely to be induced if we work with the bees when they are irritable from enforced idleness.

The Keithsburg, Ill., *News* is growing eloquent over the fact that the grape sugar refineries are gathering up old bones, rags, etc., to make its villainous stuff from. It says:

Smith's team has been hauling bones from the slaughter houses and putting them in cars for a Burlington market. These bones are used in the sugar refinery. Just think! bones in your sugar! the nasty, stinking bones. Honey, fresh from the "blessed bees" is the only pure sweet.

The bees are now working on the sand mint. They have pretty much left the corn tassels. The sand mint will last till fall, and makes most excellent honey. Thank goodness there is plenty of sand mint here in the bottom. More than can be utilized by the numerous colonies kept by our several apiarists.

Apis Mellifica in Java and Ceylon.

The following article concerning the bees taken to Ceylon and the island of Java, by Mr. Frank Benton, was written for the *Bienenzeitung*, by Mr. A. Schroder, of Trieste, Austria, and translated by Mr. A. Neighbour, of London, England, for the *Journal of Horticulture*, and it will be read with interest by the bee-keepers of America:

"The gentleman in charge of the Imperial German Consulate of Batavia, who has for years past been kind enough to keep me informed of all that takes place in the island of Java as regards bee-keeping, sent me recently a cutting from a native paper which contains some notices of the bees introduced into Java by my friend Mr. F. Benton. Thinking that any information on the acclimatization of bees in Java may be of interest so far as the history of bee-keeping is concerned, I have translated the article referred to, of which the following is an extract:

"An American bee-keeper, Mr. F. Benton, who visited Java in order to study *Apis dorsata*, and, if possible, to introduce this bee into Cyprus, and thence into Europe and America, brought 9 colonies of bees with him, 7 being from Cyprus and 2 from Palestine. New hives were procured in order to try once more to acclimatize bees in Java after the first attempt to introduce the European bee, which was made in 1878, had proved a failure. The trial was made at Tjikemueh under the direction of Mr. Messink.

"The bees were placed in the Botanical Gardens under the superintendence of Mr. Benton, who looked after them personally for 25 days. When he left, 4 queens had commenced to lay eggs, and the other colonies, including their queens, were in tolerably good condition considering the long voyage they had made. During the first fortnight after their arrival the bees were fed with sugar dissolved in water. After this time the workers from four hives began to fly out and returned laden with honey. The queens continued depositing eggs for about the three months after their arrival in Java. After that, egg laying diminished, and at last the bees quite ceased to leave the hive.

"The number of worker bees became smaller and smaller, and finally some of the colonies dwindled down so much that only the queen and a few worker bees were left. With a great deal of trouble one colony was kept alive till the end of the year. But when the western monsoon set in in 1881, the population of this colony also dwindled away, and the workers flew out no longer, probably on account of the dampness of the atmosphere.

"It is to be regretted that the second attempt to acclimatize the bee in Java has also turned out a failure, in spite of all the precautions that had been taken to make the experiment a success. The loss of all the colo-

nies was probably caused by the worker bees not finding sufficient food during the hot season, the consequence being that the queens did not receive the proper amount of food, and, therefore, discontinued laying eggs.

"The experiment to domesticate the East Indian bee (*Njiroean*) has given a better result than a previous attempt in 1877 and 1878. For the last eight months there have been two colonies of these bees in Tjikemueh with very large populations. The bees fly out and collect a great deal of honey. Eggs are deposited regularly, and without interruption. The honey of this bee is generally considered inferior in flavor, while the wax is said to be of excellent quality.

"A swarm given off by one of the colonies a short time ago has been secured, but it was no easy task. In Europe a swarm generally settles on a branch of a tree near the apiary, from which it is easy to remove the bees; but the Indian bees fly high up into the air, and do not settle till some time after."

Mr. Benton's attempt to acclimatize *Apis mellifica* in Java has unfortunately proved a failure, and I fear there is but little prospect of this bee becoming domesticated there, although I consider it quite possible if the bees, after their arrival in Java, are made to rear young queens, because the vitality of the imported queens becomes impaired during the long voyage. It would be necessary in that case to increase the population of the colonies and their stores quickly by feeding.

In Ceylon the bees that were imported by Mr. Benton have been more successful than those in Batavia. During the rainy season from May till September, the colonies were supplied with food, but in the remaining months of the year the bees collected sufficient honey from the flowering palm trees and other tropical plants for their own wants, and had even some to spare for their master. One colony swarmed three times, but, unfortunately, during the absence of the bee-keeper, the bees had been left in charge of the servants, who neglected to attend to them, so that all the three swarms flew away and settled in the jungles, where they probably perished during the rainy season.

For the last few years, experiments have been made to acclimatize the Vanilla in Ceylon, but only by artificial fertilization was it found possible to get these plants to produce mature fruit. The *Tropical Agriculturist* calls special attention to the numerous visits of *Apis mellifica* to the Vanilla blossoms, and adds that the owner of the plantation has for this reason entirely discontinued the fertilization of the Vanilla flowers by artificial means. In case the culti-

"It may be assumed that *Apis indica* is the bee referred to above. The indigenous *Apis indica* of Java was described by Latreille ("Annales du Museum d'Hist. Nat.", t. p. 179, No. 4) as *Apis Peronii*. It is hardly to be supposed that experiments should have been made to domesticate the small East Indian bee, *Apis borea*.—EDITOR."

vation of Vanilla in Ceylon should prove successful, the importation of *Apis mellifica* will have largely aided to bring about this result, and it would be quite worth while for this purpose alone to keep bees in Ceylon, even if they had to be supplied with food during the rainy season.

Prof. A. J. Cook, who each summer during several years has worked in the Michigan Agricultural College apiary, with a class of from 20 to 40 students, all entirely unused to bees, says he has found no proof of the statement that bees know their master, and are more likely to sting a stranger.—*Exchange*.

Bee Convention at Toledo, O.

The next annual meeting of the Tri-State Bee-Keepers' Association will be held on the 12, 13 and 14 of next Sept., during the week of the Tri-State Fair at Toledo, Ohio. It is customary to say that Messrs. So and So, "and other prominent bee men will be present," etc., etc. Well, we have quite a number of "prominent bee men" (prominent at home) in this region, and they know how to raise the bees, get the honey, cure foul brood, and winter the bees too; but if Mr. Heddon is well enough to be at the meeting and the fair, we will pump him on wintering, and Mr. Muth on foul brood, and Novice, if here, on general principles, and the editor of the BEE JOURNAL to fill in where the rest lack. We do not expect to have any long essays or speeches. It being the week of the fair, we expect the great attraction for bee-keepers will be the Bee and Honey Show, and such bee-keepers and their friends as desire to stay several days can bring their "eatables" and blankets with them, and camp on the fair grounds. One or more tents will be provided for such as make application to me a few days before the fair, at a cost that will pay for the use of the tents, but we hope to be able to borrow tents and so save expense.

A premium is offered for the foundation machine making the best foundation for the brood-chamber on the grounds, and two mills have already arrived for that purpose, and the makers of three other machines have promised to be here if possible.

A premium list with entry blank rules and regulations, railroad fares, and freight rates, etc., will be sent free to all applicants.

DR. A. B. MASON.
Wagon Works, Ohio.

The Northwestern Illinois, and Southwestern Wisconsin Bee Keepers' Association, will hold its next meeting on Sept. 4, 1883, at John Swanzy's, 2 miles South of Ridot, Stephenson County, Ill. There will be facilities to take persons from the station to Mr. Swanzy's.

JONATHAN STEWART, Sec.

Local Convention Directory.

1883. Time and Place of Meeting.

- Sept. 4.—Ohio State, at Columbus, O. D. Spear, Sec.
 Sept. 4.—N. W. Ill., & S. W. Wis., at Ridot, Ill. Jonathan Stewart, Sec.
 Sept. 12.—Eastern Indiana, at Richmond, Ind. M. G. Reynolds, Sec., Williamsburg, Ind.
 Sept. 12-14.—Tri-State, at Toledo, Ohio. Dr. A. B. Mason, Sec., Wagon Works, O.
 Sept. 18-20.—North American, at Toronto, Ont. A. I. Root, Sec., Medina, O.
 Oct. 9, 10.—Northern Mich., at Sheridan, Mich. O. R. Goodno, Sec., Carson City, Mich.
 Oct. 10.—Cass County, at Logansport, Ind. De Witt Brown, Sec.
 Oct. 17, 18.—Northwestern, at Chicago, Ill. Thomas G. Newman, Sec.
 Oct.—Northern Ohio, at Norwalk, O. S. F. Newman, Sec.
 Dec. 5-6, Michigan State, at Flint. H. D. Cutting, Sec., Clinton, Mich.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Honey Flora—White Sage.

The California *Rural Press* contains the following description of this great honey-producer, the white sage:

Not only is California famous for its specimens of vegetable growth of huge proportions, but also for some of much less imposing appearances. Among the latter there is no plant that has made this State more renowned than has the white or honey sage of southern California. Hardly ten years ago it was looked upon as a useless shrub, scarcely fit for sheep to browse upon. Since then the honey bee has made it famous. When it became known that honey flowed from the flowers of this plant, as it was never known to do in old Greece, and of a quality far superior, thousands of colonies of bees were located in the sage region. During our favorable years these bees gathered the honey from the flowers about them in such large quantities that many an ocean craft was weighted down with the nectar.

To all parts of the world has this delicious article been sent, and everywhere it has secured for the place from whence it came praises that no other honey had ever received. Besides the good words this State has obtained by its excellent honey, the people have received thousands of dollars which would never have entered the State if the nectar was wasted on the desert air, or if the plant in question did not exist in our midst.

It belongs to the genus *Audiberatia*, of the order *Labiata*, to which also the garden and other sages belong.

These plants are of great value as bee pasture, as they are of easy growth, will thrive on drier soil than will most other honey-secreting plants, and their season of efflorescence continues many weeks. The writer has cultivated the white sage in Alameda county, near Berkeley, and as a result he finds that it thrives remarkably, growing luxuriously on cultivated soil, and producing an abundance of bloom. It is a plant of which every apiarist should disseminate the

seeds as much as possible, so that in the course of a few years, large patches of the plants may be found in the hills and valleys in various parts of the State. By doing this, such a thing as a short honey crop will hardly ever be known.

The Rev. J. C. Nevin, of Los Angeles county, in writing of the sages lately, says: "There are at least a dozen specimens of *Audiberatia* on the coast included under the popular names of 'white' and 'black' sage. The 'white' (*Audiberatia Polyzachya*) differs very much in the form of inflorescence from all the others, and from that of the genuine sage. Its whole appearance makes it a rather striking plant, and when once known, to be easily recognized anywhere. Its range extends from Santa Barbara to San Diego. All lovers of the beautiful white honey gathered from its flowers ought to know and regard it with feelings of gratitude.

'Ball,' 'button,' or 'black' sage is undoubtedly a common name for several distinct species. Their general habit is much the same, whilst ordinarily the specific distinctions may not be so obvious. The whole appearance is more nearly like the true sage than is the 'white' above mentioned. Of the number, *A. Stachyoides*, *A. Palmeri* and *A. Clevelandi* are very closely allied and most difficult to distinguish. *A. Stachyoides* ranges from the Contra Costa mountains southward, while *A. Palmeri* and *A. Clevelandi* are confined to the southern part of the State. Just what precise form prevails around Los Angeles has not as yet been definitely settled; but it is mostly near to, if not identical with *A. Palmeri*, the typical form of which is found in San Diego county."

Notice to Iowa Bee-Keepers.

Quite a large number of bee-keepers in our State have expressed a desire for the formation of a State Association. A consultation with others has resulted in the decision not to attempt to hold a meeting during the coming State Fair, but if thought best to hold one during the time of the meeting of the State Agricultural Society at Des Moines next January. All bee-keepers who may be present at the Fair are earnestly requested to report to the Rev. O. Clute, at the Apianian Exhibit, on or before 1 p. m. of Tuesday, the 4th day of September, 1883, who will give them notice of a meeting for consultation, and also for the selection of a committee of arrangements if one is deemed necessary.

O. O. POPPLETON,
 Vice-Pres. N. A. B. K. Society.
 Williamstown, Iowa, Aug. 10, 1883.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Fairs.—To any one exhibiting at Fairs, we will send samples of the BEE JOURNAL and a colored Poster, to aid in getting up a club. The Premiums we offer will pay them for so doing. For a club of 8 subscribers to the Monthly BEE JOURNAL, or 4 Weekly, we will present Dzierzon's Rational Bee-Keeping, price \$2.00.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL.
 Monday, 10 A. M., Aug. 20, 1883.

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The demand for extracted honey is exceedingly dull; for comb honey, only fair; arrivals are plentiful. Stocks are large in the hands of corn merchants and others. Our own supply is larger than ever, and, for the present, we cannot compete with commission merchants. We may have to offer lower figures. Our prices so far were 74c. for extracted, and 14c@16c. for comb honey on arrival.

BEESWAX—Arrivals of beeswax are good at 25c@28c., and the demand is fair.

CHAS. F. MUTH.

NEW YORK.

HONEY—We take pleasure in quoting the following prices on honey, obtainable in our market: Fancy white clover, 1 lb. sections (no glass) 20c@21c; fancy white clover, 2 lb. sections (glass) 18c@20c; fair white clover, 1 and 2 lb. sections (glass) 16c@17c; fancy buckwheat, 1 lb. sections (no glass) 15c; fancy buckwheat, 2 lb. sections (glass) 13c@14c; ordinary buckwheat, 1 and 1 lb. sections (glass) 11c@13c; extracted clover honey in kegs or barrels 9c@10c; extracted buckwheat honey in kegs or barrels 7c@8c.

BEESWAX—Prime yellow beeswax 31c@33c.
 H. K. & F. B. THURBER & CO.

CHICAGO.

HONEY—There has been a marked increase in sales this week of comb honey. New crop, prime 1 lb. frames (pure white) have sold at 20c. when in fancy cases, in a small way; good many sales at 18c. for some grade 1½ to 2 lb. frames (or prize package) when well-filled and white, 18c@17c.; not quite so well filled, 15c.

Extracted is still slow, but late receipts have been riper, and there is more inquiry; 9c@10c. for choice clover; dark and buckwheat, 7c@8c.

BEESWAX—30c@33c. for prime to pure yellow.
 R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—A dry North wind in May made our honey crop short in the Southern counties, and ¼ of a crop is a full estimate for California. Not much arriving, and the small amount coming forward is mostly medium quality. For extra white, either comb or extracted, the market is firm. White to extra white comb 16c@20c.; dark to good 10c@13½c.; extracted, choice to extra white 7c@9c.; dark and candied 6c@7c.

BEESWAX—Wholesale 27c@28c.
 STEARNS & SMITH, 43 Front Street.

ST. LOUIS.

HONEY—In better demand, but readily obtainable at quotations; offerings plentiful. Largest of strained and extracted. We quote new at 16c@17c. for strained or extracted, and 14c. for comb. Jobbing sales of choice, in fancy packages, more. Old or inferior, nominal.

BEESWAX—Easy, with sales at 25c.
 W. T. ANDERSON & CO., 104 N. 3d Street.

CLEVELAND.

HONEY—New honey continues in good demand at 18c@19c. for choice 1 lb. sections, and such are readily placed as fast as received; 2 lbs. not so active, at 16c@18c. Second quality sells 14c@17c. Extracted not in demand.

BEESWAX—None in Market.
 A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—We have had a shipment the past week from J. E. Crane, and a good sized shipment from J. V. Caldwell, of Cambridge, Ill., whose honey we had last year.

We quote our market prices, as follows: White clover, one lb. combs 20c@22c.; white clover, 2 lb. combs 18c@20c.; extracted, 7c@10c.

BEESWAX—Our supply is gone; we have none to quote.
 CHOCKER & BLAKE, 57 Chatham Street.

CORRESPONDENCE

For the American Bee Journal.

A Visit to a School of Apiculture.

WM. F. CLARKE.

After a residence of over ten months in a country destitute of bees, it was a pleasure which only a bee-keeper can understand to find myself in a large apiary once more, like Mr. Heddon's, listening to the old familiar hum, and watching the varied movements of the busy little honey-gatherers. At this time (Aug. 13), there is a cessation of the liquid flow, the fall flowers not having yet come into bloom. Here and there a few heads of late white clover could be seen, which the bees were eager to rifle. The asters too, showed some blossoms; the boneset looked white, and the goldenrod yellow with promise; while the mellilot was plainly on the wane. Bee pasture was indeed scant, so that it was a good opportunity for judging the disposition of the "cross hybrids." I must give them the credit of being as peaceably-inclined as any bees I ever saw in like circumstances. Here, in an apiary of about 300 hives, with honey scarce, and queen-rearing operations going on extensively, I saw no signs of robbery or fighting, and did not detect a single angry buzz. The most exemplary order and quietness reigned supreme. There seemed to be no Satan on the scene, to "find some mischief still, for idle" bees "to do."

My chief interest in visiting Mr. Heddon at this time was to investigate the condition and prospects of his school of apiculture. As the father of this scheme, I felt naturally anxious to know how it was working. It has not been carried out as extensively as I had anticipated and hoped, owing mainly to a practical difficulty not fully foreseen at the outset. To run an apiary for profit requires constant supervision, and enough help to do the work efficiently—no more, no less. This is hardly compatible with having an infinite number of pupils to instruct in the principles and manipulations of bee-keeping. When applications began to pour in upon Mr. Heddon, in response to his advertised readiness to take a limited number of students, this difficulty loomed up, and he saw no solution of it for the present season, but in taking only so many as he could use to advantage in carrying on his own apiary. Hence he selected from about 20 applicants, 4 young men, whose replies to a string of questions appeared to single them out as especially promising. Some instinct, unerring as that of the bee in its choice of flowers, must have guided the selection of these pupils, for a likelier quartette could hardly have been formed. They are, Fred S. Carrier, Benzie Co., Mich.; Wm. Stolley, Grand Island, Neb.; F. S.

Williams, Susquehanna, Penn.; and W. Hickox, Cleveland, O. Three of the four are bee-keepers of two or three years' standing, and the fourth, though less experienced in bee-keeping, is specially helpful to Mr. Heddon, and his companions, in consequence of being a skillful short-hand writer.

We had a session of the school, which was more like a miniature bee convention, in the evening of the day I spent with Mr. Heddon, at which I obtained ample evidence of the thoroughness with which these young men are being instructed, and the usefulness of such a plan of teaching. The students were unanimous and warm in their testimony to the good they are deriving, and the ready part they took in the discussion of various intricate bee matters, bore out their testimony, and proved that these young men are being trained to understand practical apiculture most thoroughly. The best feature in the case, to my mind, is the fact that they are "enthused" with their business.

A man must have the enthusiasm of his calling, to achieve the best success in it, and the teacher who cannot create this, is a failure.

The practical difficulty I have indicated is precisely that which besets agricultural colleges. Many farmers demand that these institutions should be self-supporting, which they cannot be, even though a portion of the time is given to manual labor. Principles must be taught, and what work is done will be more or less unskilled. A school of agriculture or apiculture must be subject to these two drawbacks. You cannot take raw youths, instruct them in the theory and practice of farming or bee-keeping, and run a farm or an apiary as a source of profit at one and the same time. It would be a poor factory that was manned wholly by apprentices.

There are, and I suppose always will be, two classes of bee-keepers, the amateurs and professionals; those who keep bees for pleasure from scientific interest, and those who keep them as a source of profit, and a means of livelihood. I am but an amateur, and doubt my ability to take an apiary and manage it so as to make it very profitable, though I know the theory and manipulations pretty well. Before going into apiculture as a business, I should want to spend a season with a practical bee-keeper like Mr. Heddon. The honey market of the world must be supplied by those who keep bees for profit, and know how to make money at it. How are the practical beekeepers to be raised up? Shall we leave the thing to chance, and let men grope their way through labyrinths of failure, into the paradise of success, or find ways and means to train them for the business? If bee-keeping is to take its proper place among the industries of the world, it would seem to be necessary to provide an education for it.

Such an education must comprise, first, a knowledge of the principles of bee-culture; and second, the business management of an apiary. The first could be given in a school of apicul-

ture with a few bee hives to experiment with. I do not see how the second could be so easily and quickly imparted as by a season's work under an accomplished bee-keeper. It is one thing to be able to handle bees, it is another and a vastly different thing to manage them so as to make them pay. Mr. Heddon says that if he could have spent a season early in his career with such an apiarist as the late Adam Grimm, it would have saved him years of blundering and discouragement. No doubt many have blundered along until they have become despairing, who might have been put on the high road to success at once by an experienced teacher. Those who are only anxious to make money by selling apiarian fixtures, will not care how many blunder into hopeless discouragement, but all who wish to see bee-keeping exalted into a regular profession or business, will desiderate some plan by which apicultural capacity can be developed into success.

Mr. Heddon's pupils are of the opinion that it would pay any young man who intends to make bee-keeping a life-work, to attend a school of apiculture where only a few hives are kept for experiment, but they consider themselves highly fortunate in being drilled into the management of a large apiary, conducted with a view to dollars and cents. Any number of young men could be taught elementary principles and manipulations in a school. Only so many as are required to do the work well, can be drilled in a practical apiary. Mr. Heddon has restricted himself, the present season, to that number. The results are, that the apiary is well "tended," everything about it is in "apple-pie order," the students are well satisfied, and so is their teacher. The only regret is that, apparently all this cannot be accomplished on a larger scale.

Chicago, Ill., Aug. 15, 1883.

Prairie Farmer.

Bees Clustering Outside.

MRS. L. HARRISON.

A lady asks why her bees swarmed seven times and returned to the same hive? She says: "I saw the queen fly away with the swarm and return twice, so I know she can fly. The bees cluster on the outside of the hive and do not appear to work much. What makes them act so?"

We do not know why they did so, but if a little discipline had been applied at the right time, it would have remedied the evil. Had the old hive been removed and a new one substituted, the colony would have entered it on their return, and then it could have been placed on a new stand and the old one replaced. Yet queens are sometimes contrary, and this one might have left the new hive and returned again to the old one followed by her subjects. We have sometimes lifted off the surplus boxes from a colony acting in this manner, and removed all the brood frames,

brushing off the bees. We extracted the honey from such frames as contained it, and those that had brood were given to nuclei. Frames containing empty comb were given the bees, the surplus boxes replaced, and they were soon working with energy. If no empty comb or foundation are at hand, frames can be given them. It is very poor economy to have bees clustered on the outside of the hive during a flow of honey, and they should be induced to go to work. An extractor has the reputation of curing laziness in bees most effectually, when it is rightly applied.

We have just now been reading in the BEE JOURNAL, how a swarm of bees that clustered on the outside of a hive, built comb in a box placed near them. We once read of a jug being found in the fall full of honey, that had been thrown carelessly down near the entrance to a hive.

The nights have been quite cool for some time, and though the sun is hot during the day, the air is cool. Poor corn and honey weather. To-day (Aug. 3) the thermometer marked about 60° at 8 in the morning. There is enough honey gathered daily to keep the queens laying, which will insure plenty of workers for fall bloom. Surplus boxes should be in readiness, for if the weather is propitious a flood of honey like that of last year may soon visit us. The rainy weather of the forepart of the season was conducive to the growth of fall flowers.

Wintering Bees in Clamps.

C. J. ROBINSON.

The old problem—successful method of wintering bees—is still a mooted question, and we are justified in discussing the subject from each other's standpoint of observation, take the differing ideal modes and shake them together in a bag, then dump and mark the one that comes out first for "the coming" method. Let us have anything that tends to promote progress.

My experience with bees began while a youth, and dates farther back, perhaps, than any other American bee-keeper now living.

Winters in this climate have ever proved a serious drawback to success in the business. Were I omniscient in knowledge, I could not devise a method of wintering that would be exempt from death casualties incident to the vicissitudes of a northern climate. Situated in a cold region, we must accept of the conditions, and try again and again if we fail of success. As yet we are ignorant of the insect nature and natural history of the honey bee. Indeed, who can answer definitely three per cent. of the questions that naturally arise in the experience of beginners in bee-culture? One inquiry would be, "What mode of wintering bees is a success without casualties incident to boreal winters?" Such question, however,

is as absurd as would be the inquiry, "How can we rear the children to have all arrive at adult age?"

Many contrivers of hives claim that their "invention" contravenes all danger from cold, and renders nugatory the ungenial winter. Yet the bills of mortality and loss continue about the same.

The grand difficulty in the premises lies in our acquaintance with the faculty of the bee, and the science pertaining thereto. We fancy that bees are dependent for their well-being on the same agencies and like uses of those factors as ourselves. A moment's reflection can scarcely fail to make such supposition an obvious error. It is well known that bees are so constituted that they have the faculty of remaining torpid (chilled) during several days, and then from genial warmth, revive again. Moreover, the normal condition of bees while reposing in confinement caused by a low temperature, is a semi-dormant state in which there is scarcely any animate action, and very little consumption of vital air (oxygen) and carbonaceous matter (food), nor much waste of tissue. Hence the preaching about "pure air," unless bees be in a state of activity, is all bosh; no matter from whence it emanates.

The more inanimate bees remain, the less oxygen and food they require, and the less consequent waste of tissue and vitality (wearing out) during a given period—during winter. Therefore, the conditions that afford bees the most perfect tranquil repose through winter is the most advantageous. Bees in a torpid state repose safely in a dead-air chamber, in which there is no oxygenated atmosphere to excite vitality. They must consume oxygen, however, have pure air to respire when not in a quiescent state. The stupid reasoning that honey bees require "pure air" and "ventilation" through the winter's reign is as fallacious as would be a theory set up that "sleepers," the bear and the marmot, require fresh air for respiration during their dormant state. In studying the subject of safe wintering, we should bear in mind that the normal condition of bees is not at all times the same, but that they are in some respects like the animal sleepers and unlike other animals. It is well known that bees, while clustered in a circulating atmosphere, do not repose quietly in a temperature considerably below the freezing point. The colder it is, the greater the action—consumption of oxygen and food—to generate warmth needed to sustain life. It is the "happy mean"—near the freezing degree of temperature that affords the desideratum—quiescent state. A variation of a few degrees either above or below freezing, changes the circumstances of condition very materially. It would be the same with "sleepers." If, during the winter, the condition of bees be such that they consume large quantities of food, they thus live fast and grow old from the required expenditure of vitality and tissue, consequent on the taxation of generating warmth, or

active occupations in or both in or out of the hive; that is, they run their allotted race sooner, a sequence that is one of the factors of "spring dwindling."

It is obvious from the view presented in the foregoing that the successful mode of wintering is attained only, if at all, by the bees reposing in an atmosphere but slightly charged with oxygen, and the temperature as indicated. This end is best attained by means of "clamps" so-called, for winter quarters.

My experience with clamps extends over a period of a quarter of a century. I derived my knowledge of the clamp method first from Rev. L. L. Langstroth's manual. Mr. L. got the plan from a German (indirectly, I believe) who practices wintering bees in clamps—burying hives in about the same way potatoes are kept in "holes."

In my first experience with clamps I missed the mark—the end I now have in view for success. Through my ignorance, a failure on the part of "mother nature," I fancied that my repository for bees must be ventilated else respiration would cease, followed with death. I discovered that in such supposition I was in error. I constructed my clamps at first with air-tubes at the bottom of the clamps, and placed a chimney ventilator in the top, so as to provide fresh air circulating through the interior of the clamp. Such arrangement defeated the valuable points gained by a different arrangement which excludes the external atmosphere and provides a partial vacuum surrounding the hives. My first clamps, and such as was described in said manual, are substantially the same sort of repository as cellars.

My mode of constructing clamps is quite simple in arrangement. I first dig a pit in mellow earth some 20 inches deep, in the form I purpose packing or placing my hives to bury. Then nearly fill the pit with dry straw, thrown in loosely, place strips across the pit, on which place the hives. Now start walls made of boards, so as to provide a dead-air space all about the hives. The walls need not be nicely made, a skeleton frame work that will keep a coat of dry staw a little distance from the hives is all that is required. The vacant space in the clamp should be about equal to one-half the space occupied by the hives. All of the earth on the bottom of the clamp should be covered with straw, so as to prevent moisture from getting within the hives. A covering of earth should be put over all in the way potatoes are covered in what is called "potato holes." When the hives are deposited over the pit where they are to remain, I arrange for ventilating, that is, do not close entirely the entrance at the bottom, and have on top a "burlap," or something that allows rarified moist air to permeate upwards. I put a tube in the top of the clamp, and let it remain open until the bees within become quite dormant, and cold winter sets in, then close the ventilator until spring-like weather, when it may be opened.

It is known that bees buried under snow will winter safely, providing there is a vacant space within the hive, or surrounding it externally. Depositing bees in clamps should be as late as it can be delayed before freezing of the ground prevents the undertaking.

For the American Bee Journal.

The School of Experiments.

W. H. STEWART.

Bee-culture is a trade. Many engage in the business, but only a few succeed and become masters; such persons are possessed of an enterprising spirit. They not only love the arts mechanical, but they delight in the arts fine. They are not always asleep when their eyes are shut. They are often found performing one job mechanically with their hands, and at the same time engaged mentally solving some knotty problem—exploring new and untried fields of usefulness. Such persons are full of new plans and projects. They are never satisfied with the present state of things. Their mental feelers are ever reaching outward and onward, and coming in contact with blessings that never have been, but are to be enjoyed. Such persons never have time to be lazy. They have no time or disposition to write letters for a department of "Blasted Hopes." No difference whether they occupy a higher or lower step in the ladder of progress; either is to them but a temporary position from which they are ever climbing to the next higher. From their standpoint the world is full of beauty; every cloud has a silver lining; every shadowy vale is spanned by a beautiful bow of promise. To them the word demand means a corresponding supply. To them, bad luck in bee-keeping means improper management. If they get a fine crop of honey this year they are thankful, but not satisfied. They will strive to do better next year. It is to this class of bee-keepers that we are in debt for the present improved hive; for the present strains of bees; the improved modes of wintering bees; the improved methods and fixtures for feeding bees; artificial swarming; preventing natural swarming; preventing drones; rearing queens; supplying with artificial combs; preventing the ravages of the moth; successful handling of bees without fire and brimstone, and without being stung to death.

To this same class of bee-keepers we must continue to look for answers to the many questions not yet answered. To them we must look for ways and means by and through which the many present and future demands are to be supplied. Obstacles have ever and ever will contend for the way that leads towards the promised land of success. Another class of persons undertake bee-keeping because they are fond of honey; or, perhaps, they hope to realize large profits from a small amount of capital or labor that they think to invest in

the business. They admire the beautiful honey that the masters have put in the market, but they fail to discern the close practical application of the finely-spun theories, the never-tiring energy, the non-surrendering enterprise that has been most potent, and is so indispensable to successful bee-keeping. They are slow to pay their money for bee papers, or take the time to read one; no patience to lie awake two or three hours in the stillness of night in mental labor, devising ways and means by and through which they may realize a large crop of fine honey.

His grandfather kept bees in hollow gums, and bees in the natural state live in old hollow trees, and it is (to him) all nonsense to attempt an improvement on nature's ways and means. He believes that the world is as flat as a pan-cake, and after about two or three turns of the crank, he finds that he has had bad luck in bee-keeping, and his bees are as flat as a pan-cake, too.

The above mentioned classes of bee-keepers are the two extremes, viz.: the most successful, and the most unsuccessful.

There is another class of bee-keepers which we will call the conservatives. They are the middle men (not women). We do not know of a female bee-keeper who is not of a progressive nature. This conservative class of men are often ready to invest in bee-keeping, and sometimes are easily persuaded to use hives and other fixtures that the advanced bee-keepers have long ago laid aside; or he may, and often does, start out with the latest improvements. He learns to use those things, perhaps, tolerably well, and is perfectly satisfied. He thinks that the art of bee-keeping has been worked up to a science; that the whole truth is told; that those who propose to give any new light on the subject are fanatical crazy heads, and unworthy of his attention. Let well enough alone, is his watchword. We admit that he is right to a certain extent, for we have all learned that it is better to go slow in making great changes without first counseling with that tried and trusty teacher—experience. Yet there are those that have learned many items in the school of experience, and as they meet with partial failures, they are able to recall all those lessons, and arrange them in regular order, and then spell out along the line a supply for each demand; and yet these conservatives are ready to condemn (without fair trial) each newly discovered truth.

When it became desirable to save honey combs for repeated use, then the progressive mind gave the extractor, the value of which it is hard to over-estimate. Yet, ever ready at his post, the conservative bee-keeper, and also the conservative honey consumer raised all sorts of baseless objections to its use. It is only because of the potency of truth and usefulness that the extractor is to-day in general use. Again, when comb foundation was introduced many who thought that they knew about all that there was of bee-keeping, expressed

an opinion that it would never come into general use. Many very knowing ones dubbed it fish-bone in the honey. Yet because of its worth and usefulness it has come into general favor, even with the conservative bee-keeper.

Now comes a condition upon the bee-keepers the world over that is creating considerable alarm. They have learned to save all their beeswax, work it over into comb foundation and give it back to the bees, thereby saving them the time and labor of producing their own wax. Thus a perpetual consumption and non-production of beeswax has culminated in a wax famine. Now the question is, what shall we do for wax, and this is the most important item in all progressive bee-keeping. How can we successfully winter bees and prevent spring dwindling are questions that threaten to baffle the wisdom of the closest observers; but if these two difficulties should be overcome, the spare combs and surplus wax will be diminished in proportion to our success in preserving the bees. However, the wax must be had, and will be forthcoming in due time, but

Conservatism in vain may try,
Exhausted fields for fresh supply;
New-born thoughts must lead the van,
To fields as yet untried by man.

Banish all fear, fraternal friend,
Bee-culture has not found its end;
Although from giddy heights you peer,
Trembling lest the end be near.

Let us try what covert fields
Of art and enterprise can yield,
The astute brain and cunning hand,
Meet, then embrace, each demand.

Rural New Yorker.

Bee Hives Made of Paper.

CLARK D. KNAPP.

Those who have been the most interested in the keeping of bees, have for years been trying to invent a hive that would be equally well adapted to the cold of our winters and to the heat of midsummers. I saw in the *Rural* a short time ago an article upon the subject of bee-hives, which was illustrated, but the writer did not touch upon the question of a summer and winter home for the bees. Many a winter hive has been invented, but, as a general thing, apiarists have given no thought to the comfort of the bees in the long, hot summer days, except by boring a few holes in the hive for ventilation.

I have always thought that the hot rays of the sun in June, July and August were unhealthful for the bees in the hive, the heat blistering clear through the wood and making the inner part of the hive so hot that the industrious little fellows cannot work with any degree of comfort. Then, in addition to the sun's heat, there is the annual heat of the bees! What a hot place must the interior of the hive be for so much industry!

Now I am opposed to placing the hives in the shade. The bees need the sunshine upon the outside, but not upon the inside of the hive. They are early risers. They are up, dressed,

have breakfast and are at work early when the morning sun glistens upon the dew drops in front of their mansion. In the State of New York the bee has no time to wait for the sun to warm the damp air beneath the thick branches of some moist, moss-covered apple tree. Therefore, I put my bees in what I choose to call my summer-and-winter hive, then set them out in God's sunshine to enjoy themselves as they work.

I make my hive with an inner and an outer wall. These walls are one inch apart. Before I put the top on I take paper—old newspaper, in fact any kind of paper—and stuff the space between those walls full, pounding it down as hard as I can without bulging the boards that form the inner and outer walls. I have two half-inch top ventilators, and in the summer I give a good ventilation from the bottom. That is all the secret there is to my summer-and-winter bee hive. It can be made in any shape and after any pattern. You can have any style of frame, or it can be made without frame.

Now, reader you ask why use paper? Is not sawdust or straw just as good? I use paper because it is a non-conductor of heat. It is one of the best non-conductors of heat known. Now it stands to reason, that if paper will keep the heat of the sun out of the hive in the summer time, it will keep the heat of the bees in the hive in winter. And that is just what the bee men have been looking for for years. Try it, brother bee men, and I believe that you will well satisfied with the experiment.

For the American Bee Journal.

Bees, Flowers, Honey and Music.

G. W. DEMAREE.

The Union Kentucky Bee-Keepers' Society has just held one of those delightful social meetings which its members and others have so much enjoyed in the past. This time the meeting was held at the apiary of W. T. Stewart, located on the princely estate of Mr. M. B. Moody, four miles north of Eminence, in Henry county. On the morning of the 14th inst., I boarded the accommodation train and was landed at the flourishing town of Eminence, at an early hour, where I was met by Dr. Ed. Drane and James Drane, the latter an uncle of the Doctor, and although an aged man, he runs a fine farm, and also a fine apiary of Italian bees on it, who took me in their "rig" and drove rapidly to the place of rendezvous. I shall not soon forget the warm and cordial reception with which we met at the good graces of Mr. Stewart and lady, and Mr. Moody and family. Every breeze seemed to waft the glad words "welcome, welcome."

After the company had well gathered, President Drane called the meeting to order, and there, under the shade of the trees near the apiary, many interesting subjects pertaining to the business of bee-keeping were warmly but pleasantly discussed.

The present season has been one of unprecedented "swarming," and hence this subject was thoroughly ventilated. Most, if not all of the members of our association have had all their "theories" pertaining to the "controlling of swarming" knocked into "pie" the present season, and hence they were humble enough to be instructed by each other's experience.

After a pleasant bee talk, Mr. Moody invited the convention to adjourn to the grove, which surrounds his stately family residence, where we found a table loaded with all the good things that the blue grass regions can give. The ladies have levied a strong and lasting contribution on our gratitude for the bountiful and graceful manner in which they catered to the wants of the "inner man." After dinner was over the company gathered in the capacious parlors where they were regaled by the Misses Moody's with as fine music, instrumental and vocal, as was ever heard outside of the professional circle. What is more appropriate than bees, flowers, honey and music?

The company retired to the apiary and resumed the "bee talk," when Mr. Moody came forward, and in a jocular way said, that he wanted to test the members of the society as to whether they had any ideas of "old bee-culture," that he had a "bee tree" down in the woods, and he would order the "boys" (the farm hands) to cut it down. Some of the company were right in for the sport, but others demurred, saying that they had no inclination to handle bees "laying around loose." Mr. Moody withdrew the motion, being too magnanimous to insist on anything without universal concurrence. The tree was left standing.

W. T. Stewart read a letter from W. W. Williamson, Lexington, Ky., discussing the propriety of our beekeepers attending the convention at Toronto, and proposing an excursion trip of many Kentucky apiarists.

After drafting suitable resolutions, tendering the thanks of the society to Mr. Stewart for his fine display of bees and honey, and to Mr. Moody and family for hospitalities, the convention adjourned; after which the members lingered for sometime as though enchanted by the splendor of Mr. Stewart's finely fitted-up apiary. If there is a finer apiary in the South than Mr. Stewart's, I have no knowledge of its whereabouts. Mr. Stewart is an artist and painter, and this advantage has enabled him to make the finest display of painted hives. Nearly all his hives differ in color, and are tastily trimmed with appropriate shading.

To set off the apiary to the best advantage for the occasion, Mr. Stewart had prepared a large glass show case in which was a "stack" of beautiful section honey in the form of a pyramid, the cappiece of which was a "wee bit" of a section of about $\frac{1}{4}$ pound. On top of the case were some Muth honey jars filled with extracted honey.

This case occupied a conspicuous place in the lawn just in front of the

center group of the apiary, and was admired by all who saw it, because of the delicious contents within. The bees no less admired the white pyramid, and might be seen poised on the wing gazing through the glass with covet in their eyes.

A novel and pleasing feature about Mr. Stewart's apiary is that instead of numbering his hives with figures in the usual way, his hives are named after some of the prominent beekeepers. In the middle of the centre group is T. G. Newnan, Editor of the AMERICAN BEE JOURNAL. This is a large chaff hive, splendidly painted, and the "lettering" is beautifully and artistically executed. On the left of this central figure, and composing apart of the group, may be seen L. L. Langstroth, Dr. Dzierzon, Charles Dadant, E. Secor, G. W. Demaree, Lucy Harrison, G. L. Viallon, James Heddon, W. M. Kellogg, Ira Barber, R. Wilkin, H. Alley, A. I. Root, G. W. Ashby and O. M. Blanton. On the right of the central figure are W. R. Howard, W. F. Clarke, Mrs. Luper, C. H. Lake, H. R. Boardman, C. C. Miller, L. C. Root, J. H. Morton, H. Roop, E. B. Southwick, E. E. Hasty, G. W. Knight, J. M. Hicks, D. A. Pike, F. Benton, R. M. Argo, O. O. Poppleton, and C. N. Abbott. Immediately in front of the center group stands a fancy little tall cottage hive, neatly trimmed with light brown, this is Prof. A. J. Cook. On its right stands E. Drane, D. A. Jones, N. P. Allen, G. M. Doolittle, L. Johnson and Frances Dunham.

When the work of "lettering" is finished there will be 180 bee-keepers and writers on bee-culture in one apiary—a pretty good force you will admit. Stretching away down the line towards the honey house, are G. M. Alves, J. B. Baker, T. Balmcomb, M. M. Baldrige, A. Benedict, O. F. Bledsoe, E. L. Briggs, J. P. H. Brown, T. J. Burrill, W. H. Bussey, J. V. Caldwell, B. F. Carroll, F. B. Cheshire, R. Corbitt, C. H. Dibbern, L. J. Diel, F. L. Dougherty, J. Craycraft, J. W. Bagley, J. D. Evans, E. T. Flanagan, G. Grimm, H. S. Hackman, W. S. Hart, G. W. House, H. L. Jeffery, E. C. Jordan, A. R. Kohnke, C. F. Koch, J. E. Lay, J. Lee, M. Mahin, J. B. Mason, A. F. Moon, R. M. Osborn, E. Parmley, J. L. Peden, A. Pettegrew, J. E. Pleasants, Mrs. A. M. Sanders, G. L. Tinker, Della F. Torre, O. M. Townsend, T. L. Vondorn, W. W. Williamson, Wm. M. Rogers, S. M. Locke, J. M. Brooks, Mrs. L. C. Axtell, E. M. Hayhurst, James H. Reed, Wm. F. Kanyler, John T. Connely, C. H. Dean, and others whose names I failed to get.

Of course Mr. Stewart keeps a record of what results he gets from his colonies; without the least idea of his methods, I should presume that it would run somewhat after this fashion: D. A. Jones, 1883, 100 lbs. of extracted; queen, best Italian stock. James Heddon, queen "mis-mated," must be superseded. G. W. Demaree, too many "stripes" entirely.

Well, now, to be serious, Mr. S. claims to have taken about 100 pounds from the colony in the hive of D. A.

Jones. This, with us, is considered an extraordinary large yield from one colony, as we depend alone on white clover for surplus.

Members reported their bees in good condition, enough honey coming in each morning to keep up breeding, which will keep the workers in good trim for the fall harvest, if we are blessed with a flow of nectar.

Christiansburg, Ky.

Lewiston Journal.

Where do Bees Cluster in Winter.

W. M. F.

I have had occasion to inspect nearly 50 hives where bees have died during the past winter and spring, in this and adjoining towns. I have also observed the nature and habits of the honey bee for the last 30 years, and hence I may be allowed to speak somewhat authoritatively on the above subject. In nine-tenths of those colonies which died the past winter, I have found them clustering close together at the top of the frames, with honey at one or both ends of the hive. I refer to bees wintered on the summer stands, with chaff protection above and around them. In a few instances I have found some honey at the lower part of the frames, and the reason is obvious. I would inform Mr. Churchill, that bees do not cluster, in late fall at the top of the hive, unless the colony is quite large and fills the whole space of the frame; but, on the contrary, where they reared their brood, on the empty comb of the brood nest, let it be where it will, but usually in the centre of the hive below and between the capped honey. Usually when the brood comes out late in autumn, there is stored some honey below the brood nest, if there has been no place to store it elsewhere; when it is stored below and they have clustered where the brood was last reared, instead of going down to eat it, they invariably crawl upward, until the top is reached. When the hive is shallow, or the colony fills the frame, they will cross over the frames towards one end, if it is warm enough in the hive for them to do so, but if it is too cold, then they remain and starve. Sometimes they traverse to one end, but woe to them, they cannot live to return to the other end on account of the frost, or frigid temperature within. But, says one, the heat generated by the bees, ascends, strikes the top of the hive, spreads out horizontally, warms the honey at the ends, and thus invites the bees to follow in this direction. Why, friends, how far do you suppose heat of the bees extends horizontally, when it is so cold in the hives as to freeze the slightest vapor—when the temperature outside of the one inch board hive is 25° below zero? Not much heat outside the immediate bodies of bees, surely, unless it be directly above the space of a bee's proboscis. Hence, we must devise some plan to keep the interior of the hive in an even temperature of 45° through the winter, or build our hives

so that bees may store sufficient honey above the brood nest for their winter's consumption.

Ohio State Bee-Keepers' Convention.

The Ohio State Bee-Keepers' Association will hold a convention during State Fair week, at Columbus, O., commencing on Tuesday evening. The following programme has been arranged:

Tuesday Evening, Sept. 4.—1. Greetings and organization. 2. Annual report of Secretary and Treasurer. 3. Election of officers. 4. Annual address of the President. 5. General discussion of topics presented by members present.

Wednesday Evening, Sept. 5.—1. Address by S. D. Riegel on improvement in bee-culture as deduced from the season's operations, followed by discussion on the same. 2. Question drawer and discussion on topics presented.

Thursday Evening, Sept. 6.—1. Address or general talk by Vice-President Aaron Benedict, on the rearing and management of queens, followed by discussions of the same. 2. Question drawer and discussion of topics presented.

Conference meetings of bee-keepers and those interested will also be held each afternoon at 1 o'clock in Apiarian Hall, on Fair grounds.

The place of meeting of the convention to be decided at time of the Fair, probably in the upper room of Apiarian Hall.

Everybody who is at all interested in bees is invited to meet with the Association, and all who can bring articles for exhibition, as efforts are being made to render this department a grand success.

The State Board of Agriculture has furnished the bee-keepers a separate hall for their exhibits at the State Fair, with an upper room in which to hold meetings. Ample room will be furnished for all exhibits.

DR. H. BESSE, *Pres.*

D. SPEAR, *Sec.*

AARON BENEDICT,
Supt. Apiary Hall.

To the Bee-Keepers of California.

The National Convention has been appointed to be held at Toronto on Sept. 18, 19 and 20. I now call upon the secretaries of the various county associations of this State, and for counties having no association, on any enterprising bee-keeper who will undertake the work, to collect and make out reports for their respective localities of the number of bee-keepers, number of colonies in the spring and on hand, and amount of comb, extracted and strained honey, and of beeswax taken, or estimated to be taken during the season, and to forward them to me by the 6th of September. Send no individual reports except from counties having no association and but few scattered apiaries. I hope to hear from all parts of the

State, but unless I get satisfactory reports from the principle honey-producing counties (San Diego, Los Angeles, San Bernardino, Ventura, and Santa Barbara), and within the specified time, I shall send nothing to the convention. The former annual reports, as well as that of Dr. Miller, who, in response to a call for statistics, received only five answers from this State, where there is said to be 600 bee-keepers, have been a mere farce, unsatisfactory to those who undertook the work, and of no practical information to anybody else, and I have no desire to make a repetition in that line. Our object is not to present figures that will astonish the world, but to obtain facts, such as they are, that we may get a clearer insight into the true status of the bee-business at the present day. I can see no good reason for withholding the truth, be it flattering or not, and I hope that each individual bee-keeper will aid the secretaries in their work, by giving or forwarding to them the desired information.

WM. MUTH-RASMUSSEN.

Vice-Pres. for California N.A.B.K.S.
Independence, Inyo Co., Cal.

Ontario Convention.

The third annual general meeting of the Ontario Bee-Keepers' Association will meet in the City Hall, Toronto, on Tuesday, the 20th day of September next, during the second week of the Industrial Exhibition. As the North American Bee-Keepers' Convention meets at the same time and place, it has been arranged that the two bodies hold joint meetings in discussing matters pertaining to our common interests, as the leading bee-keepers of America are to be present. This will, undoubtedly, be the most interesting meeting of apiarists ever assembled in Canada. The venerable Mr. Langstroth and all the prominent bee-men of the United States are expected to be present. A profitable time is anticipated, and a good turnout requested. The convention will last three days. A meeting for the purely business work of our association will be held sometime during the convention, of which due notice will be given.

R. MCKNIGHT,

Pres. Ontario Bee Association.

The S. W. Iowa Bee-Keepers' Association will meet at Red Oak, Iowa, Aug. 29. Members of the society are requested to bring their apiarian implements and put them on exhibition at the fair. Our society is in a flourishing condition, having a membership of 64, and more being added to our number at every meeting. Auxiliary associations are being formed in all our counties, and southwestern Iowa will soon be one of the foremost sections of our country in apiculture. In our report will be given the number of colonies owned in the society, produce, etc.

W. J. OLIVER, *Sec.*

L. E. MERCER, *Pres.*

To Bee-Keepers of North America.

As one of the oldest of your number, I desire respectfully to remind you that the Toronto Convention will afford us all an opportunity of paying a well-earned tribute to the memory of our honored dead—Samuel Wagner, Moses Quinby, Adam Grimm, Richard Colvin and others, who did so much to elevate American apiculture to its present high position.

L. L. LANGSTROTH.
Oxford, Ohio, Aug. 23, 1883.

The Cass County Bee-Keepers' Association, organized on the 15th of August, will meet on the 10th of October, 1883, in Logansport, Ind. All persons interested in bees and honey are respectfully invited to come.

DE WITT BROWN, Sec.

SELECTIONS FROM OUR LETTER BOX

Rolling in the Buckwheat Honey.

Last spring we purchased of Mr. Doolittle an Italian business-queen. We reared about 40 queens from her. These young queens were mated in our yard by German drones, and at this date these hybrid bees are just rolling in the buckwheat honey. The weather is all we could wish, and every indication now points to a most bountiful fall harvest.

A. W. OSBURN.
Water Valley, N. Y., Aug. 17, 1883.

Why so Much Extracted Honey.

As there is so much difference in the price of extracted and comb honey, why not produce more comb and less extracted? Will we not get as much honey in the aggregate to use lower stores exclusively for brood and winter stores, and use the section boxes on top of brood frames for surplus honey? I am inexperienced, but expect to "grow up," with the start I have, to considerable of an apiary, and am anxious to know why so much extracted honey.

K. A. W.
East Liberty, Ohio, Aug. 15, 1883.

[Both comb and extracted honey will be in demand, and all can produce which ever they desire, or have the convenience for doing. The extracted honey is used for manufacturing purposes, as well as for table use, instead of syrups, fruit, etc. Both kinds are necessary. Side storing in the brood chamber is practiced by many, but the tendency is towards favoring top storing exclusively.—Ed.]

Large Fall Crop Expected.

I have not obtained any honey since the white clover I extracted in June. The bees have been getting enough honey to keep the queens laying all through the summer. They are now working on buckwheat, and the wheat fields are full of bees, working on the ragweed, which is covered with blossoms. The weather has been very dry since the middle of July, but we had a nice rain last week, and another to-day. I expect a big flow of honey between this and the middle of September.

R. GRINSELL.
Baden, Mo., Aug. 22, 1883.

Cleome.

Enclosed please find a plant that grows wild hereabouts. The bees work on it, beginning at daylight. I can, at this moment, see drops of honey in it. Can you name it?

JOHN R. CRAIG.
Beatrice, Neb., Aug. 21, 1883.

[It is Cleome, or the Rocky Mountain bee plant—an excellent honey-producer.—Ed.]

Wintering Bees in Texas.

Bees have done well in this vicinity since spring opened. Box hive men lost heavily during the latter part of winter. I put 36 up last fall, 4 of which were weak in stores and bees; to those I gave plenty of honey, by placing full boxes on top of frames, which was soon taken out by robber bees, and the weak colonies were left to starve, which they soon did. I have concluded never to try to winter a weak colony again. I also bought 9 weak colonies in January, which I tried to save by feeding, and succeeded in saving 5 of them. I commenced the spring with 36 colonies, 6 of which were very weak; they have increased to 69 by natural swarming, and I hived back and doubled about 20 swarms, and lost 15 or 20 more. They swarmed incessantly from the first of April to the 12 of July. There was a good honey flow from the 20th of June to the 8th of August; since which time robbing has been "the order of the day." I have been watching the BEE JOURNAL closely to find a plan by which this robbing could be prevented, but have never seen anything that gives satisfaction. It bothers and perplexes me worse than anything I have found in bee-keeping. My bees are mostly blacks; I have never seen an Italian robbing, and have never seen a colony of Italians robbed by other bees. I think I shall Italianize them, next spring, for this quality alone. I have taken, up to date, about 2,000 pounds of comb honey, and everything is favorable for a good fall crop.

B. L. CLEMENTS.
Queen City, Texas, Aug. 20, 1883.

Poorest Honey Crop ever Known.

This has been the poorest summer for bees ever known in Sanilac County, Mich. I commenced with 42 colonies; increased by natural swarming to 77; we had rain and cold up to Aug. 10. White clover was plenty everywhere. Since the August 10, they have been working on sweet clover, still they get but little honey in the boxes. Some of my neighbors have not taken off one box yet. I still hope for the best.

JOSEPH LEE.
Farmers, Mich.

Honey Barometer.

I have been wondering if there is interest enough in the country to give short weekly reports from three or four districts in every State, saying what the state of the honey flow is, weather, how bees are working, blooms, etc. In this way we could have a barometer all over the country. The idea adopted in the *British Bee Journal* is what I mean in "Echoes from the Hives." If this thing was arranged for now systematically, it might be worked next year. Another thing, could not sections of States establish honey depots in the nearest cities, receive the honey of the members and grade it, and so help to keep up the price.

R. F. KENDALL.
Austin, Texas, Aug. 20, 1883.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Curious Freak of Bees.

I desire Mr. Heddon to reply to this: One of my colonies of bees cast off a swarm in the middle of July, and in order to prevent the second, I cut out all their queen-cells (they were hybrids) and grafted in a cell from an Italian colony, and when cutting out the queen-cells from this hybrid colony, one cell dropped down unnoticed to the bottom of the hive, and in a few days it swarmed again with the young Italian queen, and, on examining the old hive, I found this queen-cell on the bottom, took it out and cut it open, and to my surprise I found a dead worker bee in it, and an old one at that. The mystery to me is, Why did the bees seal that cell with that dead worker bee in it and then swarm. I gave this colony a laying queen, so everything is all right.

A. RICKENBACHER.
Gahanna, Ohio, Aug. 15, 1883.

ANSWER.—I have never had a case like the one above referred to. I do not know as we have any precedent of the kind. I do know that it is one of the traits peculiar to the Italians, especially the golden variety, to cast swarms leaving no cells behind. Such acts are exceptional, of course. Sometimes we find worker combs in queen-cells, but they were hatched and grown in the cell, evidently intended by the bees for a queen. Are you sure the bees sealed up this old dead worker before or immediately after the swarming? But, no matter at which time they did it, their reasons for so doing can be hardly more than guessed at by any of us.

August Dwindling.

Who of the bee-keeping fraternity have had an experience of an August dwindling? Here in southern Ulster county, in eastern New York, on the afternoon of Aug. 16, bees in large numbers lay around my yard unable to reach their hives from being chilled, each laden with honey or pollen. But it so happened to be warm the next day, and they most all revived, though had it rained the following night, which it threatened, they would all have perished.

D. A. MARTIN.

Plattekill, N. Y., Aug. 20, 1883.

Over 600 lbs. from One Colony.

On page 398, BEE JOURNAL, Mr. Knickerbocker states that his "boss colony" has already gathered 145 pounds, with the prospect of getting 175 pounds. My "boss colony" (a full blooded Italian) has already gathered 340 pounds; but my "bossier" one (an *Americanus*) has already gathered 603 pounds, with the prospect of 50 or 100 more. This has been a good year for honey here. The honey flow has been very regular for three months, but is slackening up some now. Our main source of honey is Alfalfa.

J. F. FLORY.

Lemore, Cal., Aug. 16, 1883.

Collecting Sweet Clover Seed.

Bees are doing well here this season. Be kind enough to state in the Weekly BEE JOURNAL the best method of collecting seed from the bokhara or sweet clover.

J. C. THOM.

Streetsville, Ont., Aug. 16, 1883.

Will you please inform me through the Weekly BEE JOURNAL how the seed of the melilot is secured from the stalk, and what it is worth by the quantity?

W. M. HELLIG.

Lutherville, Md., Aug. 23, 1883.

[Its price is regulated by the "supply and demand" in the localities where it is to be sold. To secure it, mow, thresh and screen it, as you would other grain.—ED.]

Honey-Producing Plants.

We are expecting a fine display of honey-producing plants and insects injurious to bees, at the Tri-State Bee-Keepers' Association meeting and Fair. It is prepared by a student of the Michigan University. I am not positive it will be here, but expect it. Prof. Cook has written me in regard to it. The Professor has also given me a invitation to act as chief judge at the Fair at Detroit, and I expect to "obey orders."

A. B. MASON.

Wagon Works, O., Aug. 24, 1883.

"Nothing but Leaves."

In my communication on page 419, where it is said that the caps were nearly all filled with "honey," it should have read nearly all filled with leaves. The weather is again cool during the nights, and honey is coming in slowly.

H. S. HACKMAN.

Peru, Ill., Aug. 24, 1883.

Honey Yield in Ontario.

Being desirous of having my bees store surplus honey in the second story of my hives, I determined to remove a couple of sections from the brood-chamber to the upper story, and, in doing so, I was obliged to cut some of the sections apart where they had worked together, and considerable honey ran down to the bottom of the hives, making a condition unsatisfactory to the bees. What are the probable results of such removals? My hives had a strong force of working bees, with the bottom full of honey, and most of the section combs worked together. I had the second story of my hives filled with sections of comb foundation, and yet the bees would not work on the second story. I made this division only three days since, and I now find them working all right with the exception of one hive, on the front of which a large number of bees cluster. This I attribute to the unsettled condition of the bees, caused by cutting the combs, whereby the honey flowed to the bottom of the hive, causing confusion in their working. The yield of honey in this part of Ontario, this season, so far, is far above the average, and bee-keepers anticipate very large results, and well they may, when comb honey, broken up, sells at 15 cents per pound, and one-pound boxes of honey retail at 25 cents per pound; white extracted honey is sold at 12 cents per pound wholesale, and retails at 15 cents per pound. Our bees are principally Cyprians and Italians; very few black bees are to be found, and those who have them are classed among the old fogies.

J. H. PECK.

Trenton, Ont., Aug. 20, 1883.

[The removal of unfinished sections to the upper story is frequently done to induce the bees to work up there, and there will be no trouble to get the bees to clean up the honey; in fact that is, of itself, an inducement for them to store it above.—ED.]

Report for the Season.

I commenced the season with 57 colonies; some of them were by no means strong. They brought in the first pollen on April 2; one month later than usual. My first swarm issued May 18; ten days earlier than last year. It commenced to rain April 30, and continued about five days out of every week, more or less, up to June 22, when it ceased. White clover commenced to bloom the latter part of May; the bees made good use of the time between showers, and at this date the pasture fields are white with bloom. Our favorite linden commenced to bloom the first of July, and lasted for 25 days; it gives a bountiful harvest of fine honey. I sell it readily at my home market, extracted at 10 cents; comb at 15 cents per pound. One-pound sections are a new thing here; a few days ago I put a crate of one-pound sections of beautiful white comb honey in the store; as it was the first they had ever seen, it was admired by many. Bees

have swarmed too much here this year. Many wild swarms passed over; one went in the gable end of a dwelling house, at a knot hole in the weather boarding, and they are still working lively.

H. CLARK.

Palmira, Iowa, Aug. 1, 1883.

Home Markets for Honey.

I said, many years ago, that all the honey produced in the state of New York could be consumed in the State, without taking any of it to our largest cities. This may seem a broad assertion, but let bee-keepers commence, as I did 20 years ago, to dispose of their honey, and I think that they will be convinced that their country and village will consume nearly all of it. The very same families that a few years ago bought but a few pounds, will now take as many dollars' worth; and for the past few years I have had more orders by far than I could fill. Another thing, you are not only creating a home market which will increase as years roll by, but you get the cash; but if it be consigned to the best commission men, time must elapse before you get the pay, say nothing of breaking and many other contingencies. One word of caution: be careful not to try to sell honey of an inferior class for first-class; sell it for just what it is. I never have any trouble to sell it all.

Oran, N. Y.

W. P. B.

Queen's Stings, the Clovers, etc.

Two weeks ago, a Holy Land queen stung my wife on the middle finger, while she was daubing her with honey, to return her to hive No. 19, from which she had just emerged with a swarm; and, one day last week, my daughter was assisting me, and while she was preparing to kill a Holy Land virgin queen in hive No. 3, she was stung on the middle finger. My wife and daughter are my main helpers in the apiary, and they have handled hundreds of queens, and were never stung by one before. The stings were painful; both queens retained their stingers and are now doing splendidly. My 5 acres of buckwheat are in full bloom, and the bees are on it from daybreak till noon, and are on the sweet and red clovers all day. The bees are not now working on the white clover, but very little. The figwort and catnip are blooming, and dotted thick with bees from early until late. My Black-Italians (hybrids) do not work on red clover. My Syrio-Italians draw the nectar from the red clover bloom, easily and quickly. The queens all had a vacation some three weeks back, but now they are at the front, booming. The honey is the finest I ever saw. The prospects are yet splendid in favor of a fall honey harvest. We have had no rain now for ten days, and to-day it is 94° at 1 p. m.; wind northwest. I keep my 51 colonies all equal and full of bees; when one gets so full that they cannot be smoked in, to stay and work, I find the weakest hive, and, late in the evening, I shovel them up and take them to that hive and smoke them in.

Kane, Ill.

R. M. OSBORN.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price still lower, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00, or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper, shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter, on your label, notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a statement of account every week.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 50
" 200 colonies (420 pages).....	2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

BUSINESS CHANGE.—I wish to announce a change in my business. You are aware of the death of my oldest son, which occurred in May last. He had been quite a help to me. After his health was impaired, he went to the country, and I had become accustomed to miss his assistance in the business; but he had taken upon himself the care of the farm. When I found that there was no remedy for his unfortunate disease, my mind was made up to reduce my business. My grocery and seed trade was unusually heavy the past spring and summer, while my honey trade kept growing steadily. When the rush for supplies was added, I was crowded more than was pleasant. I could take no time to write a postal card, unless it was imperatively necessary. On Monday last I rented my store, etc., to a couple of young business men, and sold them my stock of groceries. I may be found, hereafter, in my honey store, on the corner lot opposite the old store. Pure Honey and Bee Keepers' Supplies, Seeds and Pure Baking Powder, will hereafter be my business.

CHAS. F. MUTH.

Cincinnati, O., Aug. 22, 1883.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS C. NEWMAN.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

Mrs. J. F. Upton gives the following notice of this book in the Bath, Maine, *Sentinel*:

A guide to the management of the apiary for profit and pleasure, by Thomas C. Newman. This work is designed to initiate beginners in bee-keeping in all the secrets of successful bee-culture. Beginning with the different races of bees, the author takes his readers along step by step, carefully explaining the different kinds of bees, illustrating each kind with the eggs and brood, explaining the terms used, the production of wax and comb, and the work done by these wonderful insects. The establishment of an apiary is next considered; the best location, time to commence, how many colonies to begin with, what kind of bees to get, how to care for a first colony, keeping bees on shares, changing the location, all of which it is indispensable for a beginner to know. It is also important to know which kind of hive is the best, how to procure the best comb honey, how to procure it for market, how it should be marketed, what to do with candied comb honey, and how to extract honey. The scientific management of an apiary is then entered into, and illustrations of all the necessary appliances introduced. There is a chapter devoted to the honey extractor and its use, and another to comb foundation and its use. The various honey-producing plants and trees are named and illustrated. Various methods for exhibiting bees and honey at county and state fairs are described. The best and safest plans for wintering bees are discussed, the book closing with some general advice to beginners. The author says of his book on Bees and Honey, "it was not designed to supersede or supplant any of the valuable works on apiculture already published, but to supply a want for a cheap work for the beginners." We most cordially recommend this work not only to beginners, who will find it invaluable, but to all who are not already familiar with the lives and movements of these industrious and intelligent little workers. The information to be gained as to their habits, manner of breeding, intelligence, energy and wonderful instincts, by reading this book alone, is enough to make one regard the bee with admiration and amazement.

PRICE—Bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

THOMAS C. NEWMAN,

925 W. Madison St., Chicago, Ill.

 A Liberal Discount to Dealers by the Dozen or Hundred.

Bingham Smoker Corner.

Large Smokers need wide shields. Bingham's have them, and springs that do not rust and break, and bellows that sparks and smoke do not enter. The Conqueror has all improvements made to date, and a 3x7 inch stove, and 5x7 inch bellows. Sent post-paid for \$1.75. Address,

BINGHAM & HETHERINGTON,
Abronia Mich.

CYPRIAN CONQUEROR.—All summer long it has been "which and father" with me and the Cyprian colony of bees I have—but at last I am "boss." Bingham's "Conqueror Smoker" did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham.
G. M. DOOLITTLE,
Borodino, N. Y.,
Aug. 15, 1882.

EXCELLING ALL.—Messrs. Bingham & Hetherington, Dear Sirs:—I am now selling your Smokers almost exclusively. You are excelling yourselves in smokers all the time.

Respectfully,
J. G. TAYLOR, Patented, 1878.
Austin, Texas, May 10, 1883.

THE VERY BEST.—The Bingham "Conqueror" Smoker is the very best thing I have tried in this line.
M. M. LINDSAY.
Fulton, Tenn., July 24, 1883.

During the following three months, Bingham Smokers will be sent post-paid, per mail, on receipt of the following prices:

The "Doctor" (wide shield)—3 1/2 in. fire tube,	\$2.00
The Conqueror (wide shield)—3 in. fire tube,	1.75
Large (wide shield)—2 1/2 in. fire tube,	1.50
Extra (wide shield)—2 in. fire tube,	1.25
Plain (narrow shield)—2 in. fire tube,	1.00
Little Wonder (narrow shield)—1 1/2 in. fire tube,	.65
Bingham & Hetherington Uncapping Knife,	1.15

With thanks for letters of encouragement, and the absence of complaining ones, we tender to our thirty-five thousand patrons our best wishes.
Very Respectfully Yours,

BINGHAM & HETHERINGTON,
Abronia, Mich., June 1, 1883.

Do not send coins in a letter. It is dangerous and increases the postage unnecessarily. Always send postage stamps, for fractions of a dollar, and, if you can get them—one-cent stamps; if not, any denomination of postage stamps will do.

The new two-cent postage stamp is to be of a metallic red color, with a vignette of Washington. It will supersede the present three-cent stamp on the 1st of October.

Sample Copies of the AMERICAN BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

Trial Trip—25 Cents.

As the season for Fairs has arrived, and wishing to be able to reach several thousands of the old-fashioned bee-men, and by the aid of the BEE JOURNAL to lift them up to higher ground, adopting newer methods and progressive ideas, we make the following very liberal offer: We will send the Weekly BEE JOURNAL three months on trial, for 25 cents. In order to pay for getting up Clubs, we will give a copy of Fisher's Grain Tables, or Scribner's Lumber and Log Book, to any one who will send us five trial subscriptions (with \$1.25); for a club of ten we will give a cloth copy of Bees and Honey; for a club of 15, a cloth copy of the 7th edition of Cook's Manual of the Apiary; for a club of 25, we will present both the Manual and Bees and Honey. If any one wants these Books for nothing, here is an excellent opportunity to get them for a little exertion.

Books at Fairs.—Those who make an exhibit at Fairs will find that an assortment of Books and Pamphlets would sell and leave them a profit for handling. We will send such, postage prepaid, at 25 per cent. discount; or if the purchaser pays express charges, we will supply any of our own publications at 40 per cent. discount.

The new Postal Note will be obtainable in a few days at the Post-offices all over the country. Then any sum from one cent to five dollars can be sent in a letter, by obtaining a Postal Note, costing only 3 cents. After October 1, small sums can be easily sent to this office for 5 cents (3 cents for the Postal Note and 2 cents postage on the letter), and there will be no need of sending postage stamps in letters, which often get all stuck together by the damp weather, or being handled while perspiring.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$5 per 100.

A Queen and a book on Queen-Rearing for \$2. See Henry Alley's liberal offer in his new advertisement.—*Adv.*

Do not let your numbers of the BEE JOURNAL for 1883 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

The Bee-Keeper's Guide;

OR,

MANUAL OF THE APIARY,

By A. J. COOK,

Of Lansing, Professor of Entomology in the State Agricultural College of Michigan.

320 Pages; 133 Fine Illustrations.

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

Read the following opinions of the Book:

All agree that it is the work of a master and of real value.—*L'Apiculteur*, Paris.

I think Cook's Manual is the best of our American works.—*LEWIS T. COLBY*.

It appears to have cut the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—*J. P. WEST*.

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—*E. H. WYNKOOP*.

This book is just what everyone interested in bees ought to have, and which, no one who obtains it, will ever regret having purchased.—*Mich. Far.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The richest reward awaits its author.—*A. E. WENZEL*.

My success has been so great as to almost astonish myself, and much of it is due to the clear, disinterested information contained in Cook's Manual.—*Wm. VAN ANTWERP, M. D.*

It is the latest book on the bee, and treats of both the bee and bees, with their implements. It is of value to all bee-raisers.—*Ky. Live Stock Record*.

It is a credit to the author as well the publisher. I have never yet met with a work, either French or foreign, which I like so much.—*L'ABBE DU BOIS*, editor of the *Bulletin d'Apiculture*, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Pulaski, N. Y.

We have perused with great pleasure this *volume* of the bee-keeper. It is replete with the best information on everything belonging to apiculture. To all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee-man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor*.

Price—Bound in cloth, \$1.25; in paper cover, \$1.00 by mail prepaid. Published by

THOMAS G. NEWMAN,
W. & Madison Street, CHICAGO, ILL.

BEE JOURNAL

VOL. XIX.

CHICAGO, ILL., SEPTEMBER 5, 1883.

No. 36.

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

The Editor of the BEE JOURNAL was prevented from attending the Kentucky State Convention, last week, by an attack of nervous prostration. His physician prescribes rest from brain labors as much as possible, for a few weeks, in order to effect a complete restoration.

The Rev. L. L. Langstroth has been invited to attend the Northwestern Bee-Keepers' Convention to be held at Chicago, Oct. 17 and 18, and accepts in the following language:

"About the invitation to attend the Convention at Chicago, and your very kind invitation to me to share your hospitalities, friend Newman, allow me to say, I accept both with great pleasure, and if nothing unforeseen should prevent, I will be glad to make the personal acquaintance of the Northwestern bee-keepers.

L. L. LANGSTROTH."

Conventions and Bee and Honey Shows are now the order of the day, and every bee-keeper should arrange to attend these helps to our pursuit, and thus aid in every way possible the advancement of the art. By looking over the columns of the BEE JOURNAL the times and places of such meetings can be ascertained, and arrangements made ahead, so that all may attend them.

The new two cent rate of postage for letters goes into effect on October 1. Three cent postage stamps will then be but little used. For all fractions of a dollar sent to us hereafter we should prefer either one-cent, or else five or ten-cent postage stamps. Do not send coins in any letter.

Honey Yield in Wisconsin.

The following items are from the Milwaukee *Sentinel* of last week:

Mr. Crain, the owner of a large number of bees at Tyron, in Dunn county, reports an extraordinary yield of honey this season, owing to the unlimited stretches of clover fields. The apiarists of Eau Galla, Waubeck, in that county, are also highly gratified with the results of the season.

James Nipe, at Spring Prairie, says his bees have stored over 10,000 pounds of honey so far this season. It has been a very good year for white honey, as clover was in blossom much longer than usual.

E. A. Morgan, of Columbus, shipped 1,000 pounds of honey to Eau Claire last week, his third shipment to that point, this season. The price received was 20 cents a pound.

T. L. Wolfenden, of Lake Geneva, recently sold 6,000 pounds of honey to a Cincinnati firm.

Excursion tickets from Cincinnati to Niagara Falls, good until Oct. 28, can be bought for \$15. Excursion tickets from any part of the South or Southwest to the Louisville Southern Exposition can be had, or from Louisville or Cincinnati Exposition. In this way, if in no other, Toronto, which is only 30 miles from Niagara Falls, may be reached cheaply.

The Summer and Fall Catalogue of E. P. Roe, Newburgh, N. Y., is received. It consists of 20 pages, and describes small fruit plants and grape vines.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey at Fairs, will sell almost a fabulous quantity of it.

Bee-Keeping in Arkansas.

The Little Rock, Ark., *Gazette* contains the following:

Apiculture or bee raising has become a great business in Devall's Bluff, and Dr. W. W. Hipolite, who is accredited with being the pioneer apiculturist in the State, carries it on extensively. Not the Doctor exactly, but by his son, Walter H. The Doctor supervises matters, however, and there are few who are better versed in the natural history of the bee than he. He has 58 colonies, or as they are sometimes called, hives, and although the season does not close until November, he has gathered 3,000 pounds of honey, a great part of which he sends to Little Rock and Hot Springs. The Doctor intends to send some fine specimens of honey in the comb and extracted honey to the Louisville Exposition. A. W. Sory, another apiculturist, has gathered 5,000 pounds this season, and carries on an extensive business. It has been stated by good authority that Arkansas honey stands second to none, and that the State is one of the best locations in the Union for successful operations in apiculture.

A fight recently occurred in Virginia City between a cat and a hive of bees, in which the bees got decidedly the best of it. The cat's attention was attracted by the bees, and thinking them some new kind of game, dabbed viciously at them as they passed in and out of the hive. At last, one day the bees got angry and poured out of the hive by the hundred, and darted for the fur of tabby. The cat rolled herself into a ball, and bit, spluttered, and clawed with all her might, but with no effect, as the bees kept stinging as diligently as ever. After a time she was taken away, and was a week recovering from the effects of the stings. She cannot be persuaded to go near the hive any more.

Fairs.—To any one exhibiting at Fairs, we will send samples of the BEE JOURNAL and a colored Poster, to aid in getting up a club. The Premiums we offer will pay them for so doing. For a club of 8 subscribers to the Monthly BEE JOURNAL, or 4 Weekly, we will present Dzierzon's Rational Bee-Keeping, price \$2.00.

Immense Yield of Honey.

The Chenango, N. Y., *Tribune* of Aug. 18, contains the following concerning an immense yield of honey in the apiary of Mr. F. E. Smith, of Chenango, N. Y.:

One of the grandest sights we ever beheld in connection with a display of bees and honey has been witnessed by large numbers of people who have lately visited Sunny Side apiary, located in this village, and owned by E. F. Smith.

On the first of May last, Mr. Smith commenced the season with 30 colonies of bees, mostly Italians and Cyprians, in improved Langstroth frames adapted to winter chaff-packing hives, having lost 7 during the winter and early spring.

The early maple and apple blossoms placed the colonies in fair condition, and the first swarm (Italians) issued May 26, in the midst of apple bloom. White clover was abundant, and commenced blooming about the 10th of June, but owing to excessive rains very little nectar was secreted during that month, and consequently the bees did very little up to July 10. After that time they commenced to boom, and upon the opening of bass-wood blossoms (about July 21), they fairly outdid themselves, and from that time onward until Aug. 10, with very little interruption, honey seemed to rain down. Many of the colonies being so numerous as to bring in upwards of 20 pounds in one day.

A record was kept of 2 colonies which we give below. For convenience we will number them 1 and 2. For further convenience we will name the parent colony of No. 1, "B," the first swarm "A," and the two frame nucleus "C." All being the outcome of No. 1 colony without any outside help except that frames of foundation were supplied fast as needed.

Record of colony No. 1, and its increase.

	A	B	C
June, capped honey.....lbs.	28	8	
" extracted honey.....		4	
July 1, capped honey.....	26		
" 18, extracted honey.....	30

" capped honey.....			8
" 13, extracted honey.....	30	15	
Total.....lbs.	437	269	55

Summary No. 1, "A," 437; summary No. 1, "B," 269; summary No. 1, "C," 55; total No. 1 and increase, 761.

"C" has also 28 one-pound boxes nearly filled, and Mr. S. expects to get at least 50 pounds of fall honey each from "A" and "B." If he succeeds, this will bring the amount

from the one colony and increase up to nearly 900 pounds. Of the above 139 pounds is comb honey in one-pound boxes, the remainder, 622 pounds, extracted. Reckoning comb honey at 20 cents per pound, and extracted at 15 cents, the result is as follows:

622 pounds of extracted honey, at 15 cents, \$93.30; 139 pounds of comb honey, at 20 cents, \$27.80; add for 20½ pounds of comb honey, at 20 cents, "C," \$4.10; add for 1 pound of wax, 30 cents; 1 new swarm of bees, \$8; 1 nucleus swarm of bees, \$7; total profits No. 1 colony and increase to date, \$140.50.

Record of No. 2 colony alone.

frames below except brood-nest of eight frames.....	34

Total.....lbs. 492

Here we have a grand total of over twelve hundred and fifty pounds of honey worth over two hundred dollars, from two colonies of bees in the spring.

One colony, which we will call No. 3, has given no honey or increase. This colony was queenless on the first of June, with only a handful of bees. A queen-cell, and a small patch of brood and eggs were added from another colony, and they are now strong, well along in the boxes, and will give a good showing.

Consequently, what honey has been taken off, was taken from 29 colonies, spring count. No honey was extracted from the brood-chamber. Over 6,000 pounds of honey has been taken to date, and there is over 700 one-pound section boxes on the hives well along, and Mr. S. believes he will get one thousand pounds more this season. This is probably the largest honey yield on record, being that over 20 per cent. of the above is comb honey in one-pound section boxes.

Sunny Side apiary can be seen by calling on the proprietor, who is thoroughly conversant with the business, and takes pride in showing his tons of honey. We have spent some time, and have taken considerable pains to get at these figures, and can vouch for all we have said. Incredible as the above report may seem to some, who know little of bees and their industry, it is true, nevertheless, and can also be substantiated by Rev. A. Eastman, of this village, who has been in attendance at Sunny Side apiary during the honey season; and by many of our citizens who have made frequent visits there. People come many miles to see this wonderful apiary and get the honey.

Many old bee-keepers who are now using the box hive of the Pilgrim fathers, are taking notes on the standard Langstroth movable frame outdoor wintering, chaff-packing hive now used by Mr. S., and also of his superior strains of Italian and Cyprian bees for future reference.

In the meantime we congratulate friend Smith on having obtained what is probably the greatest honey yield on record from 29 colonies of bees, spring count. He now has 66 colonies in prime condition.

Notice to Iowa Bee-Keepers.

Quite a large number of bee-keepers in our State have expressed a desire for the formation of a State Association. A consultation with others has resulted in the decision not to attempt to hold a meeting during the coming State Fair, but if thought best to hold one during the time of the meeting of the State Agricultural Society at Des Moines next January. All bee-keepers who may be present at the Fair are earnestly requested to report to the Rev. O. Clute, at the Apiarian Exhibit, on or before 1 p. m. of Tuesday, the 4th day of September, 1883, who will give them notice of a meeting for consultation, and also for the selection of a committee of arrangements if one is deemed necessary.

O. O. POPPLETON.

Vice-Pres. N. A. B. K. Society.

Williamstown, Iowa, Aug. 10, 1883.

Reduced Fare to Toronto Convention

President D. A. Jones, under date of Beeton, Aug. 25, 1883, writes us as follows:

I have received a letter, of which the enclosure is a copy, from Mr. Hill, Manager of the Toronto Industrial Exhibition, which is the outcome of an application which I made to him to secure reduced rates for bee-keepers in the State of Michigan. As it would receive publicity through your JOURNAL, perhaps you will be kind enough to give it insertion. There are single fare rates for the whole week of our convention.

D. A. JONES.

BEETON, Aug. 25, 1883.

H. J. HILL, Esq.—Dear Sir: Replying to yours of the 15th inst., I would say that we do not wish to advertise any reduction from regular rates, but if there are any on our line who apply to you, and you will refer the application to me, I will furnish them with certificates on which they can obtain tickets to Port Huron or Detroit, and return at excursion rates. Yours truly, D. EDWARDS.

☞ "A tired bee," says Sir John Lubbock, "hums on E, and, therefore, vibrates its wings only 380 times in a second." A brisk little bee humming on A will, on the other hand, increase its vibration to 440 per second.

Robber Bees and Robbing.

Dr. W. G. Phelps, D. D. S., gives the following in the *Practical Farmer* on the above subject:

One of the most annoying features of bee-keeping, at this season of the year particularly, is that arising from the presence of robber bees. These are in no respect a distinct race of bees, as some erroneously suppose from their peculiar black glossy appearance and active movements. They are simply bees with perverted theivish tendencies. In times when the bee pasturage is scarce they become very troublesome, and much damage and commotion may be caused in an apiary by their persistent attacks on weak hives.

Robber bees may be found in all apiaries, but more particularly in the one whose owner is careless in leaving honey exposed, or daubing sweets about. The propensity to rob seems to gradually develop itself in some bees, and even in whole colonies frequently until leaving the pursuit of honest, hard working honey gatherers, they develop a perfect mania for preying upon the gathering of other bees. No longer satisfied to gather it in minute particles "from every opening flower," they seek it after a wholesale style, from the well-filled hives of their neighbors. Thus they may be found sneaking about the entrance of other hives, endeavoring to slyly gain an admittance. If successful in passing the guards and loading up, they will soon return and bring their comrades, until at last with fierce onslaught and overpowering numbers they take forcible possession, seize upon, and transfer the stores therein to their own hive. The taste once formed, without diligent care, a whole apiary may be demoralized.

As a preventive, where the clover and basswood honey flow is over, it is best to close up the entrances of the hives, particularly the weaker ones, so that but one bee can gain entrance at a time. Thus each hive can be better defended by its owners. In

case of robbing having begun, it is well to stand a broad board close up before the entrance around which the robbers shall have to pass ere getting in. If they still persist, close the entrance entirely for a half hour and dash water upon the robbers that gather at the entrance. It may be, if they still attack it, that the hive will have to be moved to a new stand, or into a cool dark cellar until after sundown, and then taken back. By sprinkling flour on the backs of the robber bees, their hive can readily be ascertained, and I have frequently interrupted and broken up their naughty tricks by giving them a good smoking with the bellows smoker, which frightens them into remaining at home. To get ahead of robber bees when once started, the owner must be up by time in the morning, and closely watch them till after dark. Their propensity to squeeze into the smallest crevices after forbidden sweets (which gives them their glossy black appearance), requires a watchful eye to be kept upon them and a careful closing of hives and handling of sweets in their vicinity.

Western Bee-Keepers' Association.

The first annual meeting of the Western Bee-Keepers' Association will be held at Independence, Mo., Sept. 20 and 21, 1883. The association being situated in the centre of one of the best honey-producing sections of the country, and easy of access from all parts of the country, it is desirous that as many bee-keepers as can possibly attend will meet with us, and help to make it as interesting and enjoyable as circumstances will permit. In connection with the general business of such meetings, the members of the association have made arrangements for a Bee and Honey Fair, free to the world. The following premiums are offered. Members of the association will not compete for premiums offered by itself.

By the Association.

Best display of honey (comb and extracted) not less than 20 lbs. of each, in marketable shape.	\$25 00
Best 25 lbs. of comb honey.	10 00
" " " extracted " " "	10 00
Best queen, with her bees.	10 00
Best display of apianium implements, including all the principle fixtures used in the apiary.	15 00

Special Premiums free to all.

By the business men of Independence: Best 50 lbs. of comb honey in the best marketable shape, \$50.00.

By the *Sentinel*: Best package of comb honey not over 2 lbs., one year's subscription.

Judges not members of the association: All articles for display or premiums must be entered on the first day of the meeting.

Parties from a distance, who may wish, can consign their goods to either of the members of the committee. The members of the association will

do their very best to provide entertainment for all persons who may visit us.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL,
Monday, 10 a. m., Sept. 3, 1883.

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The demand for extracted honey is exceedingly dull; for comb honey, only fair; arrivals are plentiful. Stocks are large in the hands of corn merchants and others. Our own supply is larger than ever, and, for the present, we cannot compete with commission merchants. We may have to offer lower figures. Our prices so far were 7½c. for extracted, and 14½c. for comb honey on arrival.

BEESWAX—Arrivals of beeswax are good at 25½c., and the demand is fair.

CHAS. F. MUTH.

NEW YORK.

HONEY—We take pleasure in quoting the following prices on honey, obtainable in our market: Fancy white clover, 1 lb. sections (no glass) 2½c.; fancy white clover, 2 lb. sections (glass) 1½c.; fancy white clover, 1 and 2 lb. sections (no glass) 1½c.; fancy buckwheat, 1 lb. sections (no glass) 1½c.; fancy buckwheat, 2 lb. sections (glass) 1½c.; ordinary buckwheat, 1 and 2 lb. sections (glass) 1½c.; extracted clover honey in kegs or barrels 9½c.; extracted buckwheat honey in kegs or barrels 7½c.

BEESWAX—Prime yellow beeswax 31½c. H. K. & F. B. THURBER & CO.

CHICAGO.

HONEY—Sales are restricted to the present needs of dealers, nearly all of them expect lower figures, and are refusing to buy, unless large concessions from present prices are given them. 1 lb. sections well-filled, 18c.; 1 and 2 lb. sections, 18c. None but white is being taken. What is offered of last year's crop is unsalable at over 5½c. per pound. Extracted, 7½c.

BEESWAX—30½c. for prime to pure yellow. R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Receipts were comparatively large the past week, mostly of medium qualities, for which the market is not firm. Transfers are largely of a jobbing character. White to extra white comb, 15½c.; dark to good, 10½c.; extracted, choice to extra white, 7½c.; dark and candied, 6½c. — BEESWAX—Wholesale 27½c.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Quiet sale. New comb 14½c.; fancy small packages higher; strained and extracted 7½c.

BEESWAX—Easy, at 24½c. for choice. W. T. ANDERSON & CO., 104 N. 3d Street.

CLEVELAND.

HONEY—New honey continues in good demand at 18½c. for choice 1 lb. sections, and such are readily placed as fast as received; 2 lbs. not so active, at 16½c. Second quality sells 14½c. Extracted not in demand.

BEESWAX—None in Market. A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—We have had a shipment the past week from J. E. Crane, and a good sized shipment from J. V. Caldwell, of Cambridge, Ill., whose honey we had last year.

We quote our market prices, as follows: White clover, one lb. combs 2½c.; white clover, 2 lb. combs 18½c.; extracted, 9½c.

BEESWAX—Our supply is gone; we have none to quote.

CROCKER & BLAKE, 57 Chatham Street

According to the AMERICAN NEWSPAPER CATALOGUE of Edwin Alden & Bro., Cincinnati, Ohio, just published, containing over 800 pages, the total number of Newspapers and Magazines published in the United States and Canada is 13,184 (showing an increase over last year of 1,029). CORRESPONDENCE

For the American Bee Journal.

Excessive Humidity in Winter.

DR. G. L. TINKER.

Mr. S. Corneil, on page 405, of the BEE JOURNAL, gives a highly interesting table on the comparative temperature and humidity of the winter of 1880-81 with the winters of other years. The record is complete from 50 stations in the northern and western States, and in a large number extends over a period of 13 years. For these records he is indebted to our Chief Signal Service Officer at Washington, to whom bee-keepers generally are under obligations for the time and labor of preparing them.

The table indicates beyond peradventure that severe and protracted cold conjoined with an unusual humid state of the atmosphere were the chief causes of the great bee mortality of the late hard winter.

It so happened that throughout the greater part of the eastern States, including New Jersey and Maryland, that the rate of the mortality was much less than at points farther west. In the State of Maine, as indicated by the table, the cold was not below that of average winters, while the humidity was somewhat less. Mr. Plummer, of Augusta, wrote: "We have not had much snow, which all left about the 1st of March." After stating that in his vicinity there were lost only 3 out of 119 colonies, he added: "I think that this is a good report for a locality so far north." And such was the tenor of nearly all the reports from the New England States. Mr. Alley reporting: "Bees never wintered better in this vicinity." There was not the usual snow fall in the eastern States, but the middle States, and the great West were deluged with snow from the 1st of December, 1880, to the 15th of April, 1881. So long as the snow did not melt to any great extent, the bees did not appear to suffer.

When February came in the temperature began to moderate and the snow to melt. The atmosphere became damp, and continued unusually damp all through March in all of those sections where there had been heavy snow falls. Now came the struggle for existence to the bees. February witnessed a frightful mortality, but in March it became appalling. Whole apiaries were swept out of existence, and when at last summer came, less than half of all the bees in the northern States remained alive.

The table of Mr. Corneil indicates what might have been suspected, viz.: that when so great a fall of snow occurs, extending over a great part of the country, we are certain to have a very damp atmosphere during the early spring, and, consequently, an unfavorable condition for bees. It indicates, moreover, what the great

majority of bee-keepers have long felt, but have been unable to prove, viz.: that in winter excessive dampness in the hive, or in the atmosphere outside, is the most dangerous thing that can menace a colony of bees. For it appears that cold alone is not injurious to bees, nor is protracted confinement under favorable conditions. Nor yet is their normal food (honey and pollen) injurious, if the quality is good. These facts, at the present time, are indisputable. If then, dysentery be the disorder from which so many colonies of bees succumb in winter, we are forced to the conclusion that dampness is the principal cause of it.

THE POLLEN THEORY.

It is Mr. James Heddon, I believe, who has the distinguished honor of being the author of this theory which occupied to a great extent the columns of the BEE JOURNAL not long since. The agricultural press took up the refrain as if the majority of bee-keepers acquiesced in the strange doctrine, until the general reader has been led to believe that a food provided by nature for the bees is a deadly thing for them to eat in winter.

Mr. Heddon also holds parentage to the "bacteria theory," on which he was "ten to one" for a long time. Well, now, if he had only just stuck to this, his first ideal offspring, he would to-day have been standing upon solid ground, as to the probable cause of many cases of bee dysentery that have occurred in isolated apiaries or in apiaries in certain limited portions of the country.

Now, that the germ theory of disease is quite generally accepted by the most learned men of the times, it seems probable that a specific microphyte may gain entrance to the bodies of the bees by means of their food, or in some other manner, and cause dysentery. But no germ theory can be made to account for the mortality of bees in the winter and spring of 1881. If that winter had been mild, with little snow fall, and there had been great mortality, such a theory might be entertained. But neither can the pollen theory be made to so account.

As stated once before in the columns of the BEE JOURNAL, I am unable to see how the eating of pollen in winter can be a cause of dysentery in any of its forms. If it were claimed that the eating of aphide honey was a cause of some cases, the hypothesis would have at least the merit of reasonableness. But to assume that pollen, a normal food, may cause it, is quite unintelligible.

My belief is, that bees in a normal condition eat pollen all winter, not to any great extent it is true, because much nitrogenous food is not required in a comparatively inactive condition. If bees can be wintered, as they often are, without a flight for five or six months, and come out healthy, I think it must be just as difficult for others to see how pollen may cause the disease.

In the early spring of 1881, I had two hybrid colonies that had failed to

gather as much honey the previous fall as my Italian colonies, and about the 1st of March, they became short. They were discovered in time to save both from starvation by the great number of bees that were observed crawling slowly out of their hives as if very sick. Although quite cold, I opened both hives and found that they had no honey, and that they had eaten nearly all their pollen up also, as judged by the marks of their mandibles on the little pollen left. I put unsealed honey over each, and the apparently sick and dying soon revived. About four weeks afterwards they were able to take a flight. They had been gorged with pollen, but had not a sign of dysentery. If the consuming of much pollen was a cause, why did not these bees get it? But instances of this kind have been numerous.

It appears that Mr. Heddon thinks that because some colonies prepared for winter with no stores but cane sugar syrup, seem to winter better than other colonies having natural stores, the pollen theory is demonstrated. I would inquire, why not think the honey to be the cause instead of the pollen? Both being the normal food of the bees. If a child should take *cholera infantum* and die, who had taken no nourishment but milk and bread of good quality, both being normal food, would I be justified in assuming that it was the bread or the milk that caused the disease, or neither? I think I hear a common answer, neither. And so with the causation of bee-dysentery, it is neither the honey or the pollen, if of ordinary good quality.

If it can be proved (which I very much doubt) that bees will winter better on cane sugar syrup than upon their natural stores, it would demonstrate only this, that they are able to hold out longer against adverse conditions upon the former food than the latter, not that either kind of food in any case can be a cause. For instance, a man insufficiently protected and exposed to the intense cold of the Arctic regions will survive longer on a diet of tallow or animal fat than a diet of sugar, yet both of these agents, and honey also, are hydro-carbons. But cane sugar contains a larger percentage of heat producing elements than grape sugar, which is the chief constituent of honey, and animal fat contains a larger percent. than cane sugar. It would, therefore, appear that if cane sugar syrup is a better diet for bees in winter than honey, that animal fat (if the bees could be made to subsist upon it) would be better than either.

It may be assumed that my comparisons are not parallel, that bees in a state of confinement pass no feces. But my own observation, and that of many other reliable observers is, that they do, so that the question of liquid or solid food can signify nothing for or against the theory. The mere fact that pollen contains more particles that cannot be digested than honey, is no evidence that the indigestible particles in the intestines of the bees may cause dysentery. Are not the

intestines of the bees, as well as of all animals, made to carry off these same particles? If bees pass, in confinement, under favorable conditions, their feces regularly as there is every evidence that they do, from the time they are put into winter quarters whether they may have flights or not, judging from the amount of the excrement that may be raked from the bottom board of a hive every few days during the winter, in what manner are we to conclude that the indigestible particles are capable of causing disease?

Now the fact is just this, bees hold an intermediate place between warm and cold blooded animals. They are more or less active, and develop heat at all times. There is, therefore, always tissue waste, and as a part of the excrement of all animals is made up of this tissue waste, it cannot matter what the bees may subsist upon, there will be formed excrement, and I contend that this excrement is passed regularly by them throughout the winter, and the passage is only interfered with by unfavorable conditions to the life of the bees.

But if there is tissue waste in winter, there is also a necessity for nitrogenous food, and so I believe, as before stated, that bees eat a little pollen all winter, and that that little is just as necessary for their well-being to eat as is honey. I, therefore, stand for the wise and intelligent provision in nature of honey and pollen for the bees, and hold that they constitute the best food it is possible for them to have under all circumstances, and I re-assert that it is no more probable that pollen should be a cause of dysentery than that honey should be, and that it is impossible for any one to comprehend how either can be, assuming that both in any case are of good quality.

I had supposed that Mr. Heddon had abandoned the pollen theory, but from a recent article in the *BEE JOURNAL* it appears that he still adheres to the old flame. The above is, therefore, very respectfully submitted, for there is no one, perhaps, more deserving than Mr. H. for the zealous and persistent effort to unfathom the mysteries that have heretofore surrounded the causes of bee dysentery in winter.

New Philadelphia, O.

For the American Bee Journal.

Bees Injured by Heat.

N. BRAY.

I think that the bees with deformed or crippled wings, that Mr. J. D. Enas speaks of, on page 371, must have been caused by over-heating. On July 8, 1882, the thermometer went up to 108° in the shade, in this place. This day ruined all of the brood in my apiary.

The young bees were very much dwarfed in size, with only rudimentary wings, and would leave the hive much as Mr. Enas describes their leaving. The queens stopped laying

for some two or three weeks; the bees, being mostly field hands, during this time flooded the brood-chamber with honey. When the queens commenced laying, it was only a small patch of eggs at first, and increased slowly, as in early spring. We have had some extreme heat during the present season; the mercury going as high as 110°. By raising the hives from the bottom boards, and keeping them well shaded, I have escaped injury to the brood from heat; but the old bees have been injured by heat while clustering on the outside, for soon the shiny or hairless bees put in an appearance, in quite large numbers. There had been no robbing among my bees for the season, and I claim that this smooth appearance was caused by heat.

These hairless bees are short lived, about two weeks, and the most of them lie dead in front of the hives. A neighbor of mine has had brood ruined and old bees scalded in the same hives, and now some colonies are very weak. I hear persons say that all of this talk about wintering in the North amounts to nothing to us in California; this is a land of perpetual bloom; but I think a little protection from cold in winter, and protection from heat in summer, would not be amiss.

I am now devising a double-walled hive to secure my bees both from heat and cold. To-day, as I write, the mercury stands at 104°. The bees have come through with a light harvest, but the bees are in good condition.

New Almaden, Cal., Aug. 18, 1883.

Read before the Maine State Association.

Breeding the Best Queens.

J. B. MASON.

In no department of animal life is it so easy to make rapid progress towards perfection in breeding, than with the honey bee. With our stock generally, it requires a series of years to add such qualities as are deemed desirable, or to get rid of those we wish to eradicate. This, of course, is owing to the fact that conception and uterine growth is a slow process, when compared with reproduction in the insect class. With the bee, several generations can be produced in the same time that would be required to bring forth a single specimen among the mammals.

Knowing these facts, and understanding as we all may, that 16 days only is required to produce a queen from the egg, and only 25 to 30 to have it fertilized and ready to reproduce itself, it will be seen that the possibilities in the matter of perfecting our colonies, are incalculable. While in the past considerable attention has been given to matters of queen breeding, the chief attempts have been to work for color; why it is I know not, that a bright yellow color has been considered the type of beauty in the Italian bee, or why a rich, dark brown has not been accepted as the style. But such has been the fact,

and the aim of queen breeders has been to produce handsome bees, oftentimes at the sacrifice of those other qualities which alone can make them a source of profit. In a state of nature such is not the case; as a rule, the strongest and hardiest become the fathers and mothers, while the weaker must necessarily go to the wall. The result is invariably, that all animals reared in a wild state, are as nearly perfect as it is possible to have them, while it remains with man to produce inferior specimens from superior stock. In the breeding of cattle and stock generally, the rule now is to strive to improve.

We first ascertain or determine what particular points we desire to maintain and perpetuate, and to bend our best energies to the work. Already we have made vast progress in this direction. As an evidence, I can point to the vast size of our Short-horns, the milk, better and cheese qualities of our Jerseys, and horses for speed, while ten years ago a mile in three minutes for a horse to travel was considered fast. We now think we are getting a slow rate of speed unless we can drive that distance in 2:25 or less. The time has come, however, when beauty of color alone in our bees is a matter of secondary importance. Bee-keepers are demanding something more; they have found out that beauty alone will not secure them a big crop of honey, and as but few keep an apiary for experiment only, they desire, regardless of color, such stock as will guarantee them a good surplus crop, not that they object to beauty, but unless they can obtain it in connection with those other qualities which make their bees fairly remunerative, they decidedly prefer to take color as it comes, rather than to please the fancy at the expense of the pocket. Now, then, shall we rear such queens as will prove the most remunerative, and which perpetuate those qualities that will give us bees for business? In the first place, then, we must select for the queen mother such as give us hardy, long-lived, industrious, strong winged and peaceable bees. If such a colony is of the right color for style, so much the better.

A queen reared from the egg of such a colony, must necessarily prove a good one, and if she becomes fertilized by a drone from another such a colony of different strain, we have so far done all that is necessary to improve in the right direction. Keeping the above points in view, and breeding only from strong colonies, we will get the best queens possible. If we wish to rear queens, however, at a time when no honey is being gathered from the fields, we must feed our bees liberally while cell building is going forward, as there is no doubt that better queens are reared while the bees are getting stores plentifully, either from the field at large, or from the feeder at home. I do not think it makes any difference whether queens are reared under the swarming impulse or not, as regards their value, provided we supply artificially and in plenty the stores which they naturally

gather for themselves. In fact, I am rather of the opinion, that if we keep close watch and force our bees to use eggs rather than larvæ three or four days old, as they are apt to do when under the swarming impulse, we shall get a stock of queens superior to many that remain in the hive after a swarm has issued.

By careful attention to details, and by taking as much care in the selection of the drone mother as of the queen mother, and always selecting strong colonies of business bees from which to procure both queen and fertilizing drones, working for beauty as far as is practicable, yet making that point alone a secondary one, we can soon produce a strain of bees, that are not only capable of bringing us in a handsome amount of profit, but also as beautiful in color as we may desire, and so peaceable in disposition as to be handled without danger of their stings. All this will cause trouble and care on the part of the breeder, and as a rule, in order to bring breeding to absolute perfection, it must be made a specialty; the ordinary bee-keeper cannot rear perfect queens and give that time to a honey apiary as will be found necessary to give the best results. Let us look forward then to the good time coming (and it is sure to come) when our bees will be as near perfection as are our horses and cattle.

In this article, I have not attempted to give any directions for rearing queens, as they can be found by any one in the various manuals and journals of the day, but have endeavored briefly to point out the necessary requirements to make our colonies as perfect as it is possible to have them, and as the colony depends wholly upon the queen, and the drone she mates with, all that we require is to select both male and female parents, from such colonies as possess the most desirable qualities, and by following this plan out in detail, we shall soon be able to accomplish our purpose, and that, too, with positiveness and certainty, and in an exceedingly short period of time. We have the patience to work for a series of years to improve our cattle, why not have the patience then for a few months to bring this about with our bees, especially when we know that we shall attain success eventually?

Prairie Farmer.

Bees in Poetry.

S. V. COLE.

Of the little folks of nature the bees are among the most interesting. They shine not only in the field of flowers, but in the field of letters. They supply the husbandman with food, and the poet with simile and metaphor. This was especially true of the ancient poets. The Muse, in coming hither from the Golden Age of Saturn, started like the linden in Tennyson's "Amphion,"

With all her bees behind her.

If we ask what has made the bees so interesting, we find, among other

causes, that they are creatures with whom order seems to be the first law. The sluggard may go to the ant for lessons in the art of perseverance, but his education is not complete until he has graduated from the bee in the science of method, economy, and the duties of a good citizen.

A bee makes wise plans, and works for the common weal of his nation; and whatsoever he findeth to do he doeth with his might. Even when he uses his sting, he puts his whole soul into it, for he is soldier as well as citizen. This double character has led the poets to compare the bee community to a State, in which every member has his special duty; but in this comparison the bees have the advantage. Our systems are the imperfect development of ages, whereas the bees received theirs perfect in the beginning; so that Virgil says they pass their lives beneath "unchangeable laws." Shakespeare calls them

Creatures that by a rule in nature teach
The art of order to a peopled kingdom.

Virgil has sung of the bees in fuller strains than any other poet, and has interwoven fact, theory, legend in a most charming manner. The fourth book of the *Georgics*, the most perfect of his poems, is devoted to this theme. Here occurs the story of the shepherd Aristæus, who lost his bees and complained to his goddess-mother "in her chamber in the river-depth." She directs him to Proteus, the seer from whom he learns the secret of replenishing his hives.

In Virgil the bees are minified types of humanity, just as the gods are magnified ones; and they go about their business, therefore, after the manner of men:

Some seek supply of food
And by agreement labor in the fields;
Some in their narrow homes do lay the tear
Of the narcissus, and the glaucous gum
From bark of trees, to be their hive's foundations.

The contrast between the aged and sedate bees, and their more vigorous companions is very curious:

The aged guard towns, and build the combs
And mold the curious houses; 'tis their charge.
But late at night the younger ones return
Wing-weary home, their legs thick-smeared with
thyme.

One observes that the Latin poet does not forget in his figures to bring the bee-commonwealth under Roman laws and customs. In another place he speaks of their "setting out on their airy march, and pulling up the standards of the camp." Indeed, the Roman bees are soldierly in bearing, though not more so, perhaps, than their English relatives. As, in Shakespeare, some,

Like soldiers armed in their stings,
Make boot upon the summer's velvet buds,

so the Virgil,

Some stand like sentinels before the gates.

At times the whole nation is roused by an unfriendly challenge. Then it is they show themselves true Romans. Their hearts "throb with the spirit of war," says Virgil. A sound is heard "that mimics the fitful blasts

of trumpets." The excited bees "flash their wings," "whet the points of their beaks," throng around the chief's pavilion, and—*mirabile dictu!*—"with loud shouts defy the enemy!" Then comes the conflict, in which

The leaders, midmost of the battle lines,
Conspicuous for their wings, exhibit how
A mighty soul works in a narrow breast.

The analogy between bees and men is seldom carried more dangerously near the verge of the ridiculous than when a bee dies and the survivors bear out the lifeless corpse.

And form the mournful funeral train.

Time has somewhat dimmed the picture, but with its suggestion of the busts of dead ancestors and other by-gone accompaniments of a funeral, it must have been somewhat vivid in its day.

Bees, along with ants, birds, leaves, and hailstones, furnished the ancient poets with convenient similes where numbers were involved. Homer compares the Greeks gathering for battle to "swarms of closely-thronging bees, always issuing in fresh numbers from the hollow rock." Æneas, looking down on Carthage from a distance, saw the people at work on the new buildings like so many bees in summer. And Milton, whose mind was filled with classic forms, makes Satan's minions swarm to the council at Pandemonium

As Bees

In springtime, when the sun with Taurus rides,
Pour forth their populous youth about the hive
In clusters.

In American poetry, Emerson's "Humble-bee" and Whittier's "Telling the Bees" are unlike anything the ancient Muse produced, and also differ widely from each other, both in style and sentiment. The former contains the thoughts which arise in the mind of a philosopher as he calmly contemplates the

Sailor of the atmosphere

making his tiny voyages from flower to flower; while the latter is a simple and very effective appeal to the affections. Mr. Whittier's poem is founded on the curious custom, introduced from England and said to have prevailed to some extent in the rural districts of our own country, of informing the bees, in the event of a death in the family, and draping the hives in black. This was supposed to be necessary to prevent the bees from flying away in search of a new home:

Under the garden wall,
Forward and back,
Went drearily singing the choir-girl small,
Draping each hive with a shred of black.

And the song she was singing ever since
In my ear sounds on;
"Stay at home, pretty bees, fly not hence!
Mistress Mary is dead and gone!"

As good order is so strikingly exhibited in the government of the bees, for the bees, and by the bees, it seems appropriate that in Egyptian hieroglyphics the bee should represent royalty, and, in latter times, become the symbol of the French Empire. In France the royal mantle and standard

were thickly sown with golden bees, and in the tomb of Childeric, in 1653, there were discovered 300 bees made from the same precious metal.

For the American Bee Journal.

Another Dual Queen Wrinkle.

J. O. SHEARMAN.

I have about come to the conclusion in my own mind that the usual cause for two queen-ed-ness is an intent to supersede the old queen. And this is why: I had a queen in a full colony which had never gone out with a swarm (and this is her third season). She always kept her hive well stocked with bees which did well on surplus, and was, therefore, a favorite. I looked into the brood-chamber in basswood time (forepart), and found queen-cells capped, so I set the boys to watch for the swarm that I expected must come the next day or so, but the rain continued to come, with 2 or 3 cooler days, and the swarm did not come out. They still crowded the surplus chamber, so just about the last part of the basswood flow I looked in the brood-chamber for the reason, as I wanted her queen-cells. I found a queen-cell hatched naturally, also plenty of eggs and brood and the queen. Thinking they had torn down the rest of the queen-cells, and, perhaps, made away with the new candidate, I took the queen out with one comb of brood and bees, and made up a nucleus for the present, as it was a busy time. Then in a few days gave her another comb or two with bees, and noticed soon after that she filled them pretty fairly with eggs.

Now, to the point; on the 10th or 11th day after taking out the old queen, I went to the old hive after my queen-cells, and found plenty of eggs and brood in all stages. Thinking, perhaps, that the old queen had gone back (as it was only 10 feet away), I went to her hive and found her doing well enough, for a nucleus, indicating that the old colony (No. 56) had two queens at the time I took the old one away.

Then I had an after-swarm of hybrids sitting near by for this purpose, so I doubled them up with the old queen, and gave another comb of brood in the back part of the brood-chamber. A few days after this, I looked in to see if all was well, and found queen-cells, and the hybrids in the back part of the hive were building drone comb in a frame that was only partly filled at the time of doubling up.

Censuring the hybrids for murdering my \$3 queen, I looked through the hive to make sure of the case, and found her in the forepart of the hive among her own bees, and looking rather "slimmed up," as she was also at the time I took her out of No. 56 (there had been two days of rather cool weather again). Also I found 4 or 5 queen-cells on a comb that she had occupied. The hive was well stocked with bees at this time, on 8 frames, enough for breeding but not for surplus.

Now I thought I had her where she could furnish queen-cells, so I shut them up for six days, and then went for my queen-cells again, and found, instead, a young queen going around among them, and all the queen-cells destroyed.

Fearing for my \$3 queen again, I hunted her up in the very front of the hive, and doing a good business for this season of the year, and fairly fattened up to a good sized queen again. She had increased the size of her brood-nest 2 or 3 full combs, and appeared to be able to fill the hive in another week.

The young queen appeared to be unfertile, at least to me, as I believe I can tell by their personal appearance, if fertile or not. So I put her in a nucleus to keep till I see how she might "pan out." These are some of my play things. This brings these experiments up to date. Next, if they undertake to supersede old No. 56 queen again, I will see if I can set up a queen-cell establishment with her; take away the cells and put them on the back to try it again, and then see if these queens are as good as others.

New Richmond, Mich., Aug. 25, 1883.

For the American Bee Journal.

The Honey Season in New York.

JAMES MCNEILL.

The honey flow thus far in this section has been only fair. It opened well in the beginning with an abundant harvest from fruit bloom, which induced early swarming.

The much-wanted white clover bloomed profusely, but the bees did not get much more than a growing living from it. In fact, my observation during the four years that I have kept bees, leads me to hold white clover in less esteem than any other important honey plant. I have usually been able to count 25 bees on raspberries, during the same time that I have been able to find three sipping the nectar from a field of white clover. You can find bees roaring on raspberries from "early morn till dewy eve," and a passing shower drives them home, only to return again as soon as it is over. But it is only occasionally that I have been able to hear the genuine hum of industry from a field of white clover. They do not take possession of the clover field as they do of the raspberries.

The scattering English linden and basswood trees of this section bloomed abundantly, and gave the bees a fine feast. It was from this source that I obtained most of my surplus.

I hoped much from sweet clover, as I have never seen a better stand nor a more abundant bloom. But directly after basswood bloom, a period of cool weather set in, which I think must have interfered with the secretion of the nectar. The nights were exceedingly cool for the season, and some mornings were actually chilly, still the clover was alive with bees during the day, and they stored some surplus. But a first-class case of robbing could

be developed any day by a little carelessness in exposing honey.

With the advent of August a dry spell set in, and it looked as if our usual fall drouth was upon us. Happily this has been postponed by a copious rain on the night of the 18th.

Although buckwheat has been in bloom for two weeks, my bees did not settle down to actual business on this fragrant plant till the 17th. On the morning of that day it seemed as if a ship-load of honey had arrived in port, and my bees were given the contract of unloading it, with a forfeiture, if the task was not performed within a given time.

Can you explain why bees start up so suddenly to work on a plant which has been in bloom for many days?

The late rain will, I think, insure a good fall crop, as we will probably have a fine, warm fall to offset the cool, wet summer. Two years ago I took half of my crop after the middle of August. If I do the same this year I will have no reason to complain, although I cannot boast of such yields as are reported from some sections of this State.

I do not know but that I shall have to take back, in a measure, my strictures on white clover. The grounds of my apiary are sown to white clover, which I have kept closely cut with a lawn-mower till lately. They are now white with bloom. I have just been out to take a look at my busy workers, and the way that they are flitting from flower to flower over my clover lawn, leads me to earnestly wish that I had 100 acres like it. I would then be in clover as well as the bees.

Hudson, N. Y., Aug. 20th, 1883.

[Cold weather retards the nectar, and when it does get a chance, it bursts out and has the same effect as though a ship load of honey had arrived, as is mentioned above. We well knew you would change your estimate of white clover; it is one of the best of honey producers.—ED.]

Maine Bee-Keepers' Association.

The regular quarterly meeting of the Maine Bee-Keepers' Association was held in Augusta, on Thursday and Friday, Aug. 9 and 10. Although it came in a somewhat unfavorable time for a large attendance, farmers being just in the midst of the grain harvest, yet a goodly number were present at all the sessions, and the discussions were animated and interesting.

The meeting was called to order at 10 a. m. by the president of the association, Mr. F. O. Addition, who presided throughout the meeting, to great acceptance. The forenoon was chiefly taken up with business of a routine nature, and with brief discussions upon a few practical points which came up. At the opening of the afternoon session, a paper was read by Mr. J. B. Mason, of Mechanics Falls, on the subject of queen-rearing. The remainder of the afternoon was

taken up with a general discussion of that and allied subjects.

At the close of the afternoon session the members, their friends, and a few invited guests, by invitation of the editor of the *Home Farm*, visited his home and bee-yard, examined his apiary of 6 or 8 colonies, had a practical bee convention then and there, and were entertained at a little informal lawn "spread," which it is hoped proved as enjoyable to them as it was gratifying to him and his. The evening was pleasant, and passed off too quickly.

In the forenoon of the second day, a paper was read by Mr. John Reynolds, of Clinton, on "Climatic influence in bee management," particularly in regard to the spring care of bees, followed by a brief essay from the pen of Mr. O. L. Sawyer, of Gardiner, on the occasion of the losses of bees during the past winter—a discussion upon the two papers occupying the forenoon.

At the opening of the afternoon session, the report of the committee appointed to award the preferences on articles exhibited, was first presented. Following the presentation of this report there was a discussion in regard to establishing the price of honey, and uniting in its sale, and W. Hoyt, F. O. Addition and J. B. Mason were appointed a committee to correspond with producers and buyers in regard to the advisability of such a course. The next session of the association will be held at Lewiston on the second Thursday of February next, and J. B. Mason, L. F. Abbott, of the *Lewiston Journal*, and Dr. J. A. Morton, of Bethel, were appointed a committee to make arrangements for the same.—*Home Farm*.

Bee-Keeping in Mississippi.

O. M. BLANTON.

After an excellent honey flow of two months, the dry season has well set in, and bees are slowing up in gathering honey. I have taken off, up to date, over 2,200 pounds of honey from 201 colonies. The apiaries of Washington County, Miss., and Chicot County, Ark., have yielded remarkably well up to date. Mr. G. C. Vaught and myself visited the bee-keepers of Chicot and Washington counties, last week, and found bee-keeping on the boom; many making preparations for a large increase of their colonies another year. There were only nine bee-keepers working with movable frame hives, last year, in these two counties, and now there are more than 30. We visited the apiaries of Messrs. McLendon, Walter Davis, Victor and Theodore Johnson, Robert Adams, Judge Harriman, and Messrs. Irving & McShee, and were much gratified at their progress and success. All work for extracted honey. On account of sickness we failed to call on Mr. Kinkead. We were informed that his apiary was in fine condition. He and Mr. McLendon both have their own foundation machines, and supply their neighbors.

The yield of Judge Harriman's (80 colonies) and Mr. Robert Adams (30 colonies) exceeded, at that date, 200 pounds per colony. In November we expect to organize the Mississippi and Arkansas Bee-Keepers' Association.

Greenville, Miss., Aug. 23, 1883.

For the American Bee Journal.

A Starter Machine.

GEO. E. LYTLE.

I send a drawing of a Starter Machine, which is the invention of a bee-keeper near here (D. A. Sailor).

There is an awakening interest in bee-keeping here, but there are, as yet, very few bees kept in anything but box hives, yet we have a good location. There is plenty of room for enlightened bee-keepers here. Our honey season commences very early—the last of January and February. We have no trouble in wintering our bees if they have stores in plenty, so as not to starve.

Figure 1 shows a top view of the machine, which consists of a board, A,

Figure 1.

10 inches wide by about 20 long. This has two pieces, B B, tacked on, which are $6\frac{1}{2}$ inches apart. Inside C, is a block, 1 inch thick and $4\frac{1}{2}$ wide, by any convenient length, say 4 or 5 inches, to which is tacked two strips,

Fig. 2

Fig. 3

D D, 1 inch wide and 1 inch thick by 10 long, which just slip between the strips, B B. E is a lever pinned to the board at H, which pulls the block, C, down against the post, F, which comes through a hole morticed in the board, A. Figure 2 shows the post, F, with a $\frac{1}{2}$ inch hole at P, and a board, R, nailed to the bottom of the machine to stand on. Figure 3 shows the shape of one of two blocks which

are nailed to the underside of the board, A, with a hole at I. A peg is put through these holes, and also through the hole, P, in the post, F, which is between the two blocks in Fig. 3. Let the head of the post, F, when the board, A, is level, be just half the width of the section above the top of the board. Let the two wire springs, one of which is shown at Q, be just $\frac{1}{8}$ or 3-16 below the top of the post, F. These should have the point in a hole in the post, so they can sink in; as the section is pressed up against the post, they catch the starter and gauge the depth that is marked into the wood.

The section is placed around the post, F, and the starter dropped against the wire springs with the right hand, brings the lever E, against the block, C, which will mash the section against the post, and squeeze the starter to the section; then with the left arm or elbow, shove the end of the board, A, down, which shoves the section up, mashes the starter well into the wood of the section, and bends the starter down right all ready for the hive. This is by far the best machine in use to my idea, as you can do faster and better work with it than any of the others.

I forgot to state that the head of the post, F, is covered with a piece of tin to prevent the wax from sticking to the post, instead of the section.

Flat Bayou, Ark.

Ontario Convention.

The third annual general meeting of the Ontario Bee-Keepers' Association will meet in the City Hall, Toronto, on Tuesday, the 20th day of September next, during the second week of the Industrial Exhibition. As the North American Bee-Keepers' Convention meets at the same time and place, it has been arranged that the two bodies hold joint meetings in discussing matters pertaining to our common interests, as the leading bee-keepers of America are to be present. This will, undoubtedly, be the most interesting meeting of apiarists ever assembled in Canada. The venerable Mr. Langstroth and all the prominent bee-men of the United States are expected to be present. A profitable time is anticipated, and a good turnout requested. The convention will last three days. A meeting for the purely business work of our association will be held sometime during the convention, of which due notice will be given.

R. MCKNIGHT,
Pres. Ontario Bee Association.

The Cass County Bee-Keepers' Association, organized on the 15th of August, will meet on the 10th of October, 1883, in Logansport, Ind. All persons interested in bees and honey are respectfully invited to come. DE WITT BROWN, Sec.

Articles for publication must be written on a separate piece of paper from items of business.

SELECTIONS FROM OUR LETTER BOX

Well Satisfied with the Haryest.

The season is over, and I am well pleased with it. I extracted from about 80 colonies of bees, and realized about five tons of honey. A new discovery has been made in this valley, by a well-known bee-keeper named Hugo Sontag, who had about 300 colonies of bees in his apiary, in the last part of May. He found a queen with four yellow stripes on her abdomen, and the wings are scarlet. This queen he put into a colony of bees, which swarmed twice this season, and he realized 175 pounds of extracted honey from it. Mr. Sontag desires to have these queens in his whole apiary. He thinks they are more profitable than the Italians.

A. CORSEN.

Cucamonga, Cal., Aug. 22, 1883.

Verbenas.

Please tell me through the columns of the bee-keepers' standard friend, the BEE JOURNAL, the name of the enclosed bloom, and its merits as a honey plant. I never saw but very little of it here, before this season, and at this date it is thick on the road sides and pastures, and green vacant lands. It commenced to bloom about the 10th of July; there are three colors of bloom: blue, purple, and nearly white, and is about 2 to 3 feet high, and looks as though it might bloom till frost. It seems to be a favorite with the bees. They work on it from early morn till late sun down. My bees are in white, red and sweet clover up to their eyes now, early and late, and a 5-acre sheet of silver hull buckwheat bloom to breakfast on every morning at day break. We have a good harvest yet. R. M. OSBORN.

Kane, Ill., Aug. 11, 1883.

[This is one of the four quite common vervains (*Verbena hastata*). It doubtless has been plenty in certain places in the neighborhood before, but escaped observation. It is a very good honey plant.—T. J. BURRILL.]

My Honey Salesmen.

The Madison County Fair Association (held at Richmond, Ky.,) did not offer any premiums on bees or honey. I made a display of Italian bees, about 500 pounds of honey, hives, sections, smokers, knives. Given foundation press, extractor, etc., and distributed 100 pamphlets on "Honey as Food and Medicine." My display attracted considerable attention, for it was something new to most of the people. I think I attained my object, viz.: To create an interest in bee-culture, and I am sure the 100 pamphlets on "Honey as Food and Medicine," which I distributed, will sell a great quantity of honey.

C. D. MIZE.

Cleveland, Ky., Aug. 26, 1883.

Too Dry for Buckwheat.

The season here has been rather behind the average for honey, as the weather was poor in the best honey season. Bees are getting a comfortable living now, and enough to cap up unfinished work. Goldenrod is just beginning to show, and they may get something from that, if there should come a shower and warmer weather soon. There is some buckwheat in bloom, but it is too dry now for buckwheat to yield much.

J. O. SHEARMAN.

New Richmond, Mich., Aug. 25, 1883.

Tropical Honey Tree.

I send bloom and foliage from a branch broken off an ornamental tree 20 to 25 feet high, in one of the southern cities of this State, by a neighbor who is an admirer of and has a number of fine Italian bees, who was attracted to it by the hum of the bees that were around and upon it, gathering the honey. He says that it is the most wonderful attraction for bees that he ever saw; that a plate of honey out in an apiary in the month of August would not produce a greater excitement. The property on which the tree stood was occupied by a tenant, who could not give any information about it, only that it is a great attraction for bees. Will you please give us the name and nativity of the tree, and oblige.

C. C. RICHARDSON.

Tipton, Ind., Aug. 9, 1883.

[The tree is one of the numerous species of *Aralia*, natives of Tropical America, allied to the well-known Hercules club, (*Aralia spinosa*). Nothing is known of the species as honey producers, but from the structure of the flowers, one would be led to suppose they might be very attractive to bees.—T. J. BURRILL.]

Introducing a Queen in August.

The following may encourage somebody. I ordered an early queen in May; she arrived in August during a rain storm, when I did not want her. I took two frames of brood, etc. with bees adhering and put them in a small hive, smoked them and stopped them in. The next day I put the Italian queen in her cage, at the entrance of the hive, and the day after that I turned her in, smoked them, and shut them up for two days. They accepted her.

R. B. DRANE.

Edenton, N. C., Aug. 23, 1883.

Smart-Weed Honey.

The flow from smart-weed commenced 10 days ago here, and is immense. There is only 4 or 5 acres of it, and about 200 colonies of bees working on it. Each colony will gather as much from the 4 or 5 acres, as they would from 100 acres. I firmly believe if there was 400 colonies here, each would gather just as much as if there were but one. If bees were as strong in numbers at this time of the year as they are at the time horsemint blooms,

they would gather just as much honey; yet there are 50 acres of horsemint where there is one of smart-weed. It seems that every time the horsemint fails here, the smart-weed takes its place. In 1879 the horsemint failed, and there was an immense flow from smart-weed, some colonies gathering a surplus. In 1881 the horsemint yielded very little honey, and the smart-weed yielded plenty for winter supplies. Last year the horsemint flow was immense, and we got none from smart-weed.

W. S. DOUGLASS.

Lexington, Tex., Aug. 20, 1883.

How is This?

2,825 pounds of honey from 28 colonies, spring count, and the fall honey yet to be gathered. I have increased to 55. I and my better-half extracted 900 pounds in one day. I have sold about 1,400 pounds already; the basswood trees were in bloom 21 days. Some colonies gave 160 pounds. I will send a full report this fall. My honey is No. 1 basswood.

FAYETTE LEE.

Cakato, Minn., Aug. 26, 1883.

Bee Balm.

Please give me the botanical name of the enclosed. It is some kind of mint on which bees work quite extensively, but I do not know its botanical name.

J. E. VAN ETTEN.

Kingston, N. Y., Aug. 10, 1883.

[This beautiful plant is often known by the name of "Bee-Balm," or "Oswego Tea" (*Monarda didyma*). It is a native of the portions of the United States north of about 41° latitude, or from New England, northern Illinois, northward. It is closely allied to the more common "Horse-Mint," (*Monarda fistulosa*). The plant might be cultivated without trouble, but in nature it prefers moist grounds.—T. J. BURRILL.]

Honey Season in Texas a Failure.

The honey season is over in Texas, and is nearly a complete failure. Unless we have rain soon to start up fall flowers, we will have to feed heavily, the coming winter. We hope for a mild winter, and, if it comes that way, we are all right, and will be all ready for a boom in 1884.

E. P. MASSEY.

Waco, Texas, Aug. 28, 1883.

Making a Local Market.

My bees for five weeks have done no good; they are at work now like little heroes. I do not look for much fall honey, as it is dry, and there is not a large crop of flowers. I have sold all of my white clover honey at 16 $\frac{1}{2}$ and 20 cents per pound, and could have sold as much more, if I had it. I live in a village, and sold all of my honey at home. Bee men must talk it up at home. I go to a family and try to sell them honey, and if I cannot sell them but one pound, I sell it, and

will not be a week before they want wo pounds. I think honey, if managed rightly, will be readily sold at paying prices. D. R. ROSEBROUGH.
Casey, Ill., Aug. 27, 1883.

Spiked Loose-Strife Plant.

I send a box of flowers which I would like you to name in the BEE JOURNAL. It appears to be an excellent honey plant. It grows in our marshes and low lands, and grows from 6 to 8 feet high. I find the bees working on it all day long. I found some growing in the centre of a large patch of sweet clover, and as many bees working on it as the sweet clover. It commences to bloom in June, and continues to bloom until frost.

WM. K. LAWSON.

Cold Spring, N. Y.

[This is the spiked loose-strife (*Lythrum salicaria*). It is an excellent honey plant, and worthy of cultivation for this purpose, as well as for its beauty. The arrangements for cross fertilization by bees are most curious and wonderful.—T. J. BURRILL, Champaign, Ill.]

Good Season for Honey and Increase.

Notwithstanding the very severe winter, and unusually backward and wet spring, we have had a very good summer, both for honey and increase, in this part of Ontario. Some bees here swarmed as late as the 16th of August, and we extracted until the 20th; then robbing commenced, and we stopped extracting, with most of the hives full of honey. I commenced the honey season with 29 colonies, and will have about 3,500 pounds of extracted honey, when it is all taken off, and increased to about 65 colonies, by natural swarming; and then up to about 80, by taking down top stories. I have not seen any drones killed yet. We had our first frost last night. Bees are working strongly on goldenrod now.

W. G. RUSSELL.

Millwood, Ont., Aug. 29, 1883.

Manitoba Bee Plant.

I send you part of a plant which grows here wild, in the streets, and attains from 3 to 4 feet in height. It branches out very largely. If this be a bee plant, it may be of service to bee-keepers, as it will fill up the time between basswood failing and the autumn flowers. If it should be desirable as a honey-producing plant, the seed can be had in any quantity. It is a vigorous grower. It seems filled with insects, either sucking the honey or the juice of the plant itself. White clover grows here well, and the prairies are a regular bed of wild flowers. Bees are not kept here yet, but I think ought to thrive well. Trees here are very scarce, except along river banks, but the land will produce anything, being very rich and productive. Wheat, at present, is the great staple. I am at present so situated that I cannot indulge in my favorite hobby, but I take an interest in it, and from the mere love of

it, I hope some day to indulge myself in the luxury of bee-keeping. I shall not be able to attend the meeting of bee-keepers in Toronto in September next, but I trust our friends from the United States will be generously entertained by their bee friends in Ontario. I shall be much disappointed if the meeting is not of the most pleasing character.

LEWIS WALBRIDGE,
Chief Justice of Manitoba.

Winnipeg P. O., Aug. 16, 1883.

[This plant produces little or no honey. The species is not confidently recognized, but it belongs to the great sunflower family (*compositæ*), however unlike a sunflower its appearance. Its nearest relative, known to me, is the great ragweed (*Ambrosia trifida*), not uncommonly found almost everywhere along water courses and in rich, low grounds. The amount of pollen produced by this Manitoba plant is prodigious, and it was doubtless this that attracted the insects. The flowers are, when taken singly, very inconspicuous.—T. J. BURRILL, Champaign, Ill.]

Robber Flies.

Enclosed find two insects which I would like you to give me the name of through the BEE JOURNAL, together with any other information of them you may have. I will give the heaviest and largest as No. 1, which I find to be very destructive to bees, killing them all day long, and it seems that it only kills bees when returning with their load. I have killed as many as five in one day, among my bees.

No. 2, the sharpest, kills a great many, but not as many as the other. The cause may be it does not take so much to do it.

Bees have done very well in this country, considering the most of them are in box hives and hollow logs. A neighbor and myself are all that keep bees in movable comb hives, and we began this season, and some of the old bee-keepers tell us we will do no good, as this country will not produce the honey, but we have many honey-producing plants and shrubs.

DR. S. L. YORNER.

Brush, Tenn., Aug. 4, 1883.

[They are both species of robber flies. No. 1 is the one often called the bee killer (*Trapania apivora*). One of these insects, watched during one day, was known to have killed 141 bees. As the juices only of the prey are sucked, the number may not appear so surprising, supposing the purpose of catching the bees is for food.

No. 2 is another species of the same family (*Asilus sericeus*), and has similar habits. Make a hoop of wire bent so as to form a circle 9 inches across with the two ends so bent as to enter

a hole in the end of a stick three or more feet long. On the wire hoop sew a bag-shaped net of mosquito-netting, or some similar stuff. Let the bag be about 12 to 15 inches deep. With this one may soon learn to catch these desperadoes, swinging the net in one hand.—T. J. BURRILL, Champaign, Ill.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Bees with Hairy Feet.

Enclosed I send you several dead Holy Land and Italian bees. Please examine them and tell me what you know of bees having such feathery or hairy toes, and did you ever see such bees before? I have thousands of them in all my crosses with the Holy Lands, Italians and blacks. They are good workers. I want to know if they have longer tongues than the original or not? They are very docile and gentle. We have had a fine rain for the past 48 hours, 4 inches of water fell, and white clover is blooming again. My bees have taken a fresh fever to swarm. I had one swarm today, and all of my hives are full of bees and honey. The sun shines very hot, 90° in the shade at noon to-day.

R. M. OSBORN.

Kane, Ill., Aug. 26, 1883.

ANSWER.—The bees enclosed in your letter were so mashed that one could discern only that they once bees. None of the peculiarities you mention were distinguishable.

May we ask you, dear reader, to speak a good word for the BEE JOURNAL to neighbors who keep bees, and send on at least one new subscription with your own? Our premium, "Bees and Honey," in cloth, for one new subscriber to the Weekly, or two for the Monthly, besides your own subscription to either edition, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00, or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper, shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter, on your label, notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a statement of account every week.

Trial Trip—25 Cents.

As the season for Fairs has arrived, and wishing to be able to reach several thousands of the old-fashioned bee-men, and by the aid of the BEE JOURNAL to lift them up to higher ground, adopting newer methods and progressive ideas, we make the following very liberal offer: We will send the Weekly BEE JOURNAL *three months on trial, for 25 cents*. In order to pay for getting up Clubs, we will give a copy of Fisher's Grain Tables, or Scribner's Lumber and Log Book, to any one who will send us five trial subscriptions (with \$1.25); for a club of *ten* we will give a cloth copy of Bees and Honey; for a club of 15, a cloth copy of the 7th edition of Cook's Manual of the Apiary; for a club of 25, we will present both the Manual and Bees and Honey. If any one wants these Books for nothing, here is an excellent opportunity to get them for a little exertion.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

Do not send coins in a letter. It is dangerous and increases the postage unnecessarily. Always send postage stamps, for fractions of a dollar, and, if you can get them—one-cent stamps; if not, any denomination of postage stamps will do.

Special Notice.—We will, hereafter, supply the Weekly BEE JOURNAL for one year, and the seventh edition of Prof. Cook's Manual of the Apiary, bound in fine cloth, for \$2.75, or the Monthly Bee Journal, and the Manual in cloth for \$1.75. As this offer will soon be withdrawn, those who desire it should send for the book *at once*.

BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

Mrs. J. F. Upton gives the following notice of this book in the Bath, Maine, *Sentinel*:

A guide to the management of the apiary for profit and pleasure, by Thomas G. Newman. This work is designed to initiate beginners in bee-keeping in all the secrets of successful bee-culture. Beginning with the different races of bees, the author takes his readers along step by step, carefully explaining the different kinds of bees, illustrating each kind with the eggs and brood, explaining the terms used, the production of wax and comb, and the work done by these wonderful insects. The establishment of an apiary is next considered; the best location, time to commence, how many colonies to begin with, what kind of bees to get, how to care for a first colony, keeping bees on shares, changing the location, all of which it is indispensable for a beginner to know. It is also important to know which kind of hive is the best, how to procure the best comb honey, how to procure it for market, how it should be marketed, what to do with candied comb honey, and how to extract honey. The scientific management of an apiary is then entered into, and illustrations of all the necessary appliances introduced. There is a chapter devoted to the honey extractor and its use, and another to comb foundation and its use. The various honey-producing plants and trees are named and illustrated. Various methods for exhibiting bees and honey at county and state fairs are described. The best and safest plans for wintering bees are discussed, the book closing with some general advice to beginners. The author says of his book on Bees and Honey, "it was not designed to supersede or supplant any of the valuable works on apiculture already published, but to supply a want for a cheap work for the beginners." We most cordially recommend this work not only to beginners, who will find it invaluable, but to all who are not already familiar with the lives and movements of these industrious and intelligent little workers. The information to be gained as to their habits, manner of breeding, intelligence, energy and wonderful instincts, by reading this book alone, is enough to make one regard the bee with admiration and amazement.

PRICE—Bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

THOMAS G. NEWMAN,

925 W. Madison St., Chicago, Ill.

 A Liberal Discount to Dealers by the Dozen or Hundred.

Bingham Smoker Corner.

Large Smokers need wide shields. Bingham's have them, and springs that do not rust and break, and bellows that sparks and smoke do not enter. The Conqueror has all improvements made to date, and a 3x7 inch stove, and 5x7 inch bellows. Sent post-paid for \$1.75. Address,

BINGHAM & HETHERINGTON,
Abronla Mich.

CYPRIAN CONQUEROR.—All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am boss. Bingham's "Conqueror Smoker" did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham.

G. M. DOOLITTLE,
Brooklyn, N. Y.,
Aug. 15, 1882.

EXCELLING ALL.—Messrs. Bingham & Hetherington, Dear Sirs:—I am now selling your Smokers almost exclusively. You are excelling yourselves in smokers all the time.

Respectfully,

J. G. TAYLOR,
Austin, Texas, May 10, 1883.

THE VERY BEST.—The Bingham "Conqueror" smoker is the very best thing I have tried in that line.
Fulton, Tenn., July 24, 1883. M. M. LINDSAY.

During the following three months, Bingham Smokers will be sent post-paid, per mail, on receipt of the following prices:

The "Doctor". (wide shield)—3½ in. fire tube, \$2.00
The Conqueror (wide shield)—3 in. fire tube, 1.75
Large..... (wide shield)—2½ in. fire tube, 1.50
Extra..... (wide shield)—2 in. fire tube, 1.25
Plain..... (narrow shield)—2 in. fire tube, 1.00
Little Wonder..... (narrow shield)—1¾ in. fire tube, .65
Bingham & Hetherington Unpacking Knife..... 1.15

With thanks for letters of encouragement, and the absence of complaining ones, we tender to our thirty-five thousand patrons our best wishes.
Very Respectfully Yours,

BINGHAM & HETHERINGTON.
Abronla Mich., June 1, 1883.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

The Original
BINGHAM
Bee Smoker

Books at Fairs.—Those who make an exhibit at Fairs will find that an assortment of Books and Pamphlets would sell and leave them a profit for handling. We will send such, postage prepaid, at 25 per cent. discount; or if the purchaser pays express charges, we will supply any of our own publications at 40 per cent. discount.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Do not let your numbers of the BEE JOURNAL for 1883 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference

NOTICE.

We have just completed the largest and best lot of Smokers ever manufactured. Prices by Mail:

2 inch.....	Double Blast.....	\$1.50
3 ".....	Single ".....	1.00
2½ ".....	Double ".....	1.75
3½ ".....	Single ".....	2.00

Special inducements to those who buy to sell again.

THE BEST BEE BOOK

"Of all the books on bee-keeping, QUINBY'S NEW BEE-KEEPING stands pre-eminently at the head, in my opinion." Sincerely Yours,
April 11, 1883. G. M. DOOLITTLE.

Sent by Mail, Post-paid, for \$1.50.

OLDEST BEE PAPER IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

VOL. XIX.

CHICAGO, ILL., SEPTEMBER 12, 1883.

No. 37.

THE AMERICAN BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

The Editor of the BEE JOURNAL being unable to attend the National Convention, it will be represented by the Rev. W. F. Clarke, of Guelph, Ont., who is duly authorized to take subscriptions and orders for any of our publications.

Mr. James Heddon has been on a tour up into Northern Michigan, in order to recruit his health, and the *Dowagiac Times* contains a long letter from him concerning his trip, which is interesting and humorous.

We have received a catalogue of "Holland Bulbs and Plants for fall planting," from Hiram Sibley & Co., Rochester, N. Y., and Chicago, Ill. It is nicely gotten up and beautifully illustrated.

The firm name of Crocker & Blake, under which E. E. Blake and F. L. Ripley have transacted business for the past ten years at Boston, Mass., is changed to Blake & Ripley. This is the honey firm of Boston.

"The New Zealand and Australian Bee Journal" is the title of a new bee periodical published at Auckland, New Zealand. It is well edited by a progressive bee-master, and should receive a hearty support by the bee men of Oceanica. It is edited and published by Mr. H. H. Hayr, Monthly, at 6s. a year, and contains 12 pages and a cover.

Articles for publication must be written on a separate piece of paper from items of business.

Reduced Fares to Toronto.

We have received from President D. A. Jones, the Programme of the Toronto Exhibition, and Mr. Jones writes us that he has had Thursday, Sept. 20, set apart as "American Visitor's Day," in honor of our American visitors.

We have had several inquiries about excursion rates from Chicago to Toronto, as mentioned by Mr. Jones in *Gleanings*, as follows:

Announce return tickets at single fares on all railroads in Canada from the 17th to the 22d of September; $1\frac{1}{2}$ fares for excursion tickets from the 10th to the 22d of September. I am arranging hotel accommodations. Urge every one who possibly can get here, to come. There will be special excursions from many points in the United States very cheap, to the Falls and Toronto. I hear of one from Kentucky, Cincinnati, Pennsylvania, New York, Chicago, etc., but cannot get particulars yet.

We have made inquiries at the Grand Trunk Railway offices in Chicago, and they know nothing of it. We can get the regular Excursion Return Tickets from Chicago to Toronto for \$20, but none both ways for one fare, as Mr. Jones mentions.

Regular excursion tickets from Cincinnati to Niagara Falls, good until Oct. 28, can be bought for \$15. Excursion tickets from any part of the South or Southwest to the Louisville Southern Exposition can be had, or from Louisville to Cincinnati Exposition. In this way, if in no other, Toronto, which is only 30 miles from Niagara Falls, may be reached cheaply.

President D. A. Jones, under date of Beeton, Aug. 25, 1883, writes us as follows:

I have received a letter, of which the enclosure is a copy, from Mr. Hill, Manager of the Toronto Industrial Exhibition, which is the outcome of an application which I made to him to secure reduced rates for beekeepers in the State of Michigan. As it would receive publicity through

your JOURNAL, perhaps you will be kind enough to give it insertion. There are single fare rates for the whole week of our convention.

D. A. JONES.

BEETON, Aug. 25, 1883.

H. J. HILL, Esq.—*Dear Sir*:—Replying to yours of the 15th inst., I would say that we do not wish to advertise any reduction from regular rates, but if there are any on our line who apply to you, and you will refer the application to me, I will furnish them with certificates on which they can obtain tickets to Port Huron or Detroit, and return at excursion rates.

Yours truly,

D. EDWARDS.

We have written to Mr. Jones to try to get an order on the Chicago Office of the Grand Trunk Railway to sell us as many tickets as are needed at the rate for one way for the round trip, and it will pay those who go to either write to us, or call at this office en-route.

The new Postal Notes are now obtainable, and should be sent in letters for all small sums. Each of the 6,500 money-order offices have been supplied with books containing the Postal Notes. New York received 20 books, and the other offices from that number to one book. Each book contains 500 notes. In addition, each office has been furnished with a plying punch and blanks, to be used in the business. A uniform fee of 3 cents is charged for each note, payable at the office of issue. The office at which the note is made payable must be selected by the sender, and the note is payable at that office only. Each note is made payable to the bearer, and in this respect the note is of the nature of a legal tender. It is no more safe than it is to send postage stamps or bank bills in letters. Absolute safety can be had only when regular money orders are obtained.

There is now no excuse for sending postage stamps for small sums, except at offices too small to issue the Postal Notes or Money Orders. Be sure to get these Postal Notes drawn on the Madison St. Station, Chicago, Ill.

Hunting Bees in the Woods.

Mr. C. Norris, of Traverse City, Mich., writes as follows:

Being a reader of your valuable paper, the *Weekly BEE JOURNAL*, I am very anxious, and desire that some of your readers who have had successful experience in hunting wild honey bees, would give their experience in detail; what kind of feed to bait them on, and take the bees from their tree and bring them home successfully, and the best bait to use that bees will come to and carry off when the flowers are giving a flow of nectar, and oblige one wishing to learn to capture wild honey bees.

Mr. F. M. Johnson gives his experience in hunting bees as follows:

You require a small box, which can be made of any kind of wood. The box is of a slanting shape, and should be made according to the following dimensions: Bottom 4x6 inches; sides, 4 inches at one end beveled down to 1½ inches at the other; end pieces, one, 4x4 inches, the other 1½ deep by 4 inches long. The top should be a separate piece, and made as follows: Width, 4 inches, whole length 12 inches; cutting down 4 inches on end for handle, and inserting a glass 3x1 inches, flush with the under side at the other end, as near the end as convenient.

The box should contain a piece of honey comb about 1½ inches in thickness, which should be scented with bee bait (the directions for making this are given below), covering the bottom of the box. Taking the box in the left hand, and the cover in the right, and approaching the bee while at work on the flower or shub, you insert the box under the bee, and quickly putting the cover on the top (in such a manner that the light can shine in), you have the bee secure in the box; then put the box on a stake 3 or 4 feet high, taking care not jar the box more than necessary. Then shove the cover down so as to shut out the light from the glass, when the bee will go to work on the honey, which can be ascertained by holding the ear to the box, as it will cease its "humming" as soon as it commences on the comb. Then the cover can be taken off and the bee will remain on the honey. Then take a position where you can have an unobstructed view of the box and its surroundings, and wait for the bee to come out, which it will do in from one to three minutes, and commence circling in the air, gradually enlarging the circles until it finds its latitude, at which it will immediately start in a direct line for its home, and here care must be taken to accurately mark the direction it goes. You must now wait for a short time, when the bee will return and re-enter the box, which it will repeat as long as the box remains. If the tree should be near by the other bees will accompany it on its second or third return; if at a great distance it will take a longer period for the bees to "double up."

If you have gotten 15 or 20 bees at work on the line you can safely take the box to a point as far distant, in the course the bee has taken, as you choose, being careful not to pass where the bee is likely to tree, as they will not follow the other way. Now, open the box again, and if you are on the line the bees will find it in a very few minutes. If they do not you will know that you are off the line, or have passed the tree, and should move your box to a point that you know is on the line. This is to be repeated until you run the bee to its tree.

If you have but a few bees it will be necessary to shut them in the box and move them in this manner from 30 to 60 rods at a time, then open your box and wait for them to go and return. This is to be repeated until you have found the tree.

Cross lining is important. If anything should prevent you from following the bee in a direct line from where you first start it, you can move the box a distance to the right or left and start it again, by which means you can center the bee on some prominent object, whereby you can invariably locate the tree within a radius of 5 or 6 rods.

Half an ounce of tincture of annis mixed with a half dozen drops of oil of organum, to be kept in an air-tight bottle.

Instead of using honey in your box, put a quantity of granulated sugar in a bottle and dissolve it with cold water until it becomes a thick syrup, and fill the comb in the box with this liquid, which is better than the real honey.

Ontario Convention.

The third annual general meeting of the Ontario Bee-Keepers' Association will meet in the City Hall, Toronto, on Tuesday, the 20th day of September next, during the second week of the Industrial Exhibition. As the North American Bee-Keepers' Convention meets at the same time and place, it has been arranged that the two bodies hold joint meetings in discussing matters pertaining to our common interests, as the leading beekeepers of America are to be present. This will, undoubtedly, be the most interesting meeting of apiarists ever assembled in Canada. The venerable Mr. Langstroth and all the prominent bee-men of the United States are expected to be present. A profitable time is anticipated, and a good turnout requested. The convention will last three days. A meeting for the purely business work of our association will be held sometime during the convention, of which due notice will be given.

R. MCKNIGHT,
Pres. Ontario Bee Association.

 The Cass County Bee-Keepers' Association, organized on the 15th of August, will meet on the 10th of October, 1883, in Logansport, Ind. All persons interested in bees and honey are respectfully invited to come.

DE WITT BROWN, Sec.

The Curse of Adulteration.

The *Prairie Farmer* discusses the subject of food adulteration in the following strain, and indicates the remedy:

In Great Britain the laws are stringent and more rigidly enforced than elsewhere, but still it is admitted to be a great evil even in the "United Kingdom." In Germany the extent to which adulteration of food, and almost everything which enters into commerce is carried, is appalling. The most of the wines brought from Germany are villainous imitations of pure articles, loaded with drugs and unfit to be taken into the stomach. We do not know what we drink, nor hardly what we eat, nor can a physician predict with any certainty the effect of his prescriptions on account of their adulteration. Community at large is in a measure to blame in this matter; indifference on the part of the public enables those who engage in these nefarious operations to ply their vocations with impunity. The laws on the statute books against the adulteration of articles of food and drink are, therefore, almost a dead letter. Unless complaint is made, the public authorities take no notice of these things, and no private citizen cares to take it upon himself to make complaints of the manufacture or sale of such articles, and thus the disreputable business goes on in every direction. There is scarcely an article of food, except fresh vegetables and fruits, that is free from adulteration. Seemingly many persons engaged in these pursuits have deluded themselves into believing that such tampering with food has become legitimate, from the fact that the great public permits itself to be imposed upon with impunity. Nevertheless, the whole business is neither legitimate nor honest. It is a species of fraud that ought not to be tolerated. Articles are sold for what they are not, and very often they contain deleterious and poisonous substances that should never enter the human stomach.

We might fill our columns with analyses made by chemists in this country and Europe, of adulterated articles now sold as human food, embracing nearly everything in use for that purpose, but it is unnecessary. Suffice it that flour, butter, lard, sugar, coffee, tea, spices, canned fruits, and other leading articles of diet are especial objects of the adulterators' arts.

Who will point out the remedy for this gigantic evil? We would call the attention of the State Board of Health to it in Illinois. Perhaps there are cases of the use of poisonous ingredients in some of these fraudulent imitations or adulterations of food, which would bring those who are producing them within the purview of that body's authority, and lead to a few wholesome examples of condign punishment for infractions of the law in such cases made and provided.

Local Convention Directory.

1883. *Time and Place of Meeting.*
- Sept. 12.—Eastern Indiana, at Richmond, Ind.
M. G. Reynolds, Sec., Williamsburg, Ind.
- Sept. 12-14.—Tri-State, at Toledo, Ohio.
Dr. A. B. Mason, Sec., Wagon Works, O.
- Sept. 18-20.—North American, at Toronto, Ont.
A. I. Root, Sec., Medina, O.
- Sept. 20.—Ontario, at Toronto, Ont.
R. McKnight, Pres.
- Sept. 20-21.—Western, at Independence, Mo.
- Sept. 26.—Tuscarawas Val., at Newcomerstown, O.
Herbert Denman, Sec., Coshocton, O.
- Oct. 6.—Marshall Co., at Marshalltown, Iowa.
J. W. Sanders, Sec., Le Grand, Iowa.
- Oct. 9, 10.—Northern Mich., at Sheridan, Mich.
O. R. Goodloe, Sec., Carson City, Mich.
- Oct. 10.—Cass County, at Logansport, Ind.
De Witt Brown, Sec.
- Oct. 17, 18.—Northwestern, at Chicago, Ill.
Thomas G. Newman, Sec.
- Oct.—Northern Ohio, at Norwalk, O.
S. F. Newman, Sec.
- Nov. 3.—Mahoning Valley, at Newton Falls, O.
L. Carson, Sec.
- Dec. 5-6, Michigan State, at Flint.
H. D. Cutting, Sec., Clinton, Mich.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Bee & Honey Show at Lexington, Ky.

Messrs. Williamson & Bro. made an excellent display at the Lexington Fair, and were highly complimented on every side. The following notices were in the Lexington papers:

Mr. Russell White, of Maysville, a prominent young bee-keeper, who attended our Fair Wednesday, said he never saw such a beautiful display of honey before, as the display made by Messrs. Williamson & Bro., of this city. Mr. White had just returned from the great Southern Exposition at Louisville, and saw several honey displays there, and all combined were nothing compared with the display he saw at our Fair.

The display of honey by the Messrs. Williamson, was the finest and most complete on exhibition, and shows the excellent taste of our enterprising townsmen, whose 7 colonies of bees in this city alone, gathered 1,800 pounds of this beautiful honey.

Mr. White said if the Messrs. Williamson had taken their display to Louisville, they would beyond doubt, carried off the premium, which was \$50; but they preferred to remain at home and carry off the blue ribbon.—*Evening News.*

The first display that struck our attention upon entering the Hall building was Williamson & Bro.'s display of honey of all descriptions in and out of comb, some dark-colored and rich, and some as clear as an octagonal diamond. Mr. Williamson was awarded the premium unanimously, and a beautiful silver medal hung from the top jars within the casing.—*Gazette.*

Williamson & Bro. made one of the largest collections and handsomest displays of honey ever seen at the Fair.—*Transcript.*

The National Convention.

The National Bee-Keepers' Association, will hold its Annual Convention in the City Hall and Council Chamber in the city of Toronto, on Tuesday, Wednesday and Thursday, the 18th, 19th and 20th days of September, during the second week of Canada's Great Fair. All the railroads in Canada will issue tickets during this week, good to return, up to Saturday night 22d, at single fare for the round trip. Special excursion rates will be arranged from various parts of the United States, of which due notice will be given. Those who intend being present may be kept posted on the latest excursion rates, etc., by addressing me, and also that I may arrange hotel accommodation. Private lodgings will, if possible, be secured for those who desire it, and every effort will be made to make everybody comfortable. A grand meeting is anticipated. D. A. JONES, President.

The quarterly meeting of the Marshall County Bee-Keepers' Association, will be held at the Court House, in Marshalltown, Iowa, on Saturday, Oct. 6, at 10.30 A. M. Subject for discussion, "Fall and Winter Care." All interested, in this and adjoining counties, are invited, for we hope to have a good meeting, and one of benefit to all.

J. W. SANDERS, Sec.
Le Grand, Iowa.

The next regular meeting of the Mahoning Valley Bee-Keepers' Association will be held at Newton Falls, O., on the first Saturday of November, 1883. L. CARSON, Pres.
E. W. TURNER, Sec.

The "Bad Boy" Abroad.—We have just received from the publishers a book with the above title, giving the humorous experiences of a Bad Boy in Europe. It will drive the "blues" miles away, and is warranted to create laughter in the hearts of those who never laughed before. It is handsomely illustrated and bound. Price, paper cover, 25 cents; bound in cloth, 60 cents, and it will be sent to any address, post-paid, upon receipt of the price, by J. S. Ogilvie & Co., publishers, 31 Rose street, New York.

A Watertown (N. Y.) man, who has kept an account of the weather, claims that it invariably repeats itself, and gives the following as the result of his observations, viz.: All years ending in 9, 0 or 1 are extremely dry; those ending in 2, 3, 4, 5 or 6 are extremely wet; those ending in 7 or 8 are ordinarily well balanced; those ending in 6 have extremely cold winters; those ending in 2 have an early spring; those ending in 1 have a late spring; those ending in 3 and 4 are subject to great floods.

The Rev. L. L. Langstroth has been invited to attend the Northwestern Bee-Keepers' Convention to be held at Chicago, Oct. 17 and 18, and accepts in the following language:

"About the invitation to attend the Convention at Chicago, and your very kind invitation to me to share your hospitalities, friend Newman, allow me to say, I accept both with great pleasure, and if nothing unforeseen should prevent, I will be glad to make the personal acquaintance of the Northwestern bee-keepers."

L. L. LANGSTROTH.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL.
Monday, 10 a. m., Sept. 10, 1883.

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The demand for extracted honey is exceedingly dull; for comb honey, only fair; arrivals are plentiful. Stocks are large in the hands of corn merchants and others. Our own supply is larger than ever, and, for the present, we cannot compete with commission merchants. We may have to offer lower figures. Our prices so far were 7@9c. for extracted, and 14@16c. for comb honey on arrival.

BEESWAX Arrivals of beeswax are good at 25@28c., and the demand is fair.

CHAS. F. MUTH.

NEW YORK.

HONEY—White clover and basswood in 1 and 2 lb. sections, 18c. Dark and second quality, 14c.; extracted white clover in kegs and barrels, 11c.; dark, 9c.

BEESWAX—Prime yellow, 30@31c.

H. K. & F. B. THURBER & CO.

CHICAGO.

HONEY—Comb honey has been bought with more freedom this week and prices of last week have been fully sustained. The cool weather has started up the usual fall trade, and activity is the order of the hour. In selecting out the best consignments (with the exception of one round lot taken by merchants from Dakota Territory), our demands are chiefly local. Extracted honey has not been sought for to any extent, yet there is an improvement over last week in the amount sold. Comb honey, extra white 1 lb. sections, 15@17c.; comb honey, extra white 1½ to 2 lb. sections, 15@17c.

BEESWAX—Steady and quiet, at 25@31c., as to color, etc.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—There is a moderate supply of comb and extracted of common quality, but offerings of extra choice comb are very light. The sales being effected are within range of unchanged figures. White to extra white comb, 16@20c.; dark to good, 10@13½c.; extracted, choice to extra white, 7½@8½c.; dark and candied, 8½@9c.

BEESWAX—Wholesale, 27@28c.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Quiet sale. New comb 14@15c.; fancy small packages higher; strained and extracted 7½c.

BEESWAX—Easy, at 24@25c. for choice.

W. T. ANDERSON & CO., 104 N. 3d Street.

CLEVELAND.

HONEY—New honey continues in good demand at 18@19c. for choice 1 lb. sections, and such are readily placed as fast as received; 2 lbs. not so active, at 16@18c. Second quality sells 14@17c. Extracted not in demand.

BEESWAX—None in Market.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—We quote our market at 18@20c. for 1 lb. white clover; 18@19c. for 2 lb. white clover. Extracted is in good supply, and selling from 9@10c.

BEESWAX—Our supply is gone; we have none to quote.

BLAKE & RIPLEY, 57 Chatham Street.

CORRESPONDENCE

For the American Bee Journal.

Non-Excellencies of the German Bee.

T. A. HOUGAS.

Mr. Osburn is correct in saying, on page 408, "there are few that have the boldness to come forward and advocate the good traits of character of the German bee" (not the blacks). His next sentence is, "I know that one who has the independence to advocate the good qualities of the German race of bees, must expect to call down upon his head the scorn, the disapprobation and disgust of the great mass of bee-keepers of to day." While we are not disposed to "scorn" or "disapprove" any one for their views on any subject, yet we beg to disagree quite frequently. In this case we must disagree upon the good (?) qualities of the German race of bees.

"In the first place they excel as comb builders." While we must admit the truthfulness of this statement in a large degree, yet it is not strictly true, all points considered. For an instance, take a colony of German bees and place them in an empty hive; let them fill it with comb, brood and honey; then take a colony of Italian bees, place them in a similar condition. As soon as both are full of comb, brood and honey, place them in the August sun, and see which combs are the first to give away. I have seen hives that were filled by the German bees, standing side by side of those filled by the Italians, and the contents of the former were all melted down, while the latter stood it all right.

"They excel as rapid workers to draw out foundation;" perhaps they do; but I can see no difference.

"They excel as pioneers to strike out from the brood-chamber (and out of the queen's way) to store their honey;" yes, and they excel in striking straight out for you, when you lift a frame out of the hive.

"They excel in keeping their hives full of workers to gather the crop;" this has never proved true, in the least, under my observation.

"All other conditions being favorable, they excel as non-swarmlers, when you give them plenty of room."

"All other conditions being favorable." 'Tis well said; they need favorable conditions.

"When you give them plenty of room." Again, well said; who would not excel under such circumstances?

In the above mentioned article there is nothing told but the good (?) qualities of the German bee, but he does not stop to tell that 100 German bees to every one Italian bee will take wing while handling. Mr. O. forgot to tell that an Italian bee will live and grow fat on flowers that a German bee would starve to death on. Perhaps he does not rise early enough in

the morning to see that the Italians are at work from one-half to three-quarters of an hour earlier in the morning, and as much later in the evening than the German race. It seems to me that this would make considerable difference in a whole season's work. All are too familiar with the bee moth to need any notice. If Mr. O. tries the cross he speaks of, I would advise him to lay in a supply of bee veils, gloves and smokers for mutual safety.

Henderson, Iowa, Aug. 27, 1883.

Rural New Yorker.

The Outlook in Apiculture.

PROF. A. J. COOK.

In the way of growth and real progress, bee-keeping compares well with other manual labor pursuits. It is capable of proof that in the past ten years the number of bee-keepers, the product in honey, and the cash value of the proceeds of the apiaries in the country have more than doubled. The apiarian apparatus, and the methods of manipulation have also, in many respects, been entirely revolutionized. The last decade knew nothing of extracting, as practised to-day; nothing of our exquisite sections for comb honey, nothing of the valuable comb foundation. The associations devoted to apiculture number more in single States to-day than they did in the entire country ten years ago. We have nine periodicals ably conducted, one of which is a weekly. There are four or five excellent books which are selling by thousands. And our agricultural associations, instead of offering a few cents, or, perhaps, a dollar as a premium for honey, and sandwiching the honey in between syrup and sugar, now give most liberal premiums, and in some cases furnish a separate building for the exhibition of honey bees and the varied apparatus belonging to the apiary.

This growth is not the result of over-praise, as some assert. True, as with all pursuits, success finds a ready tongue, while failure hides its head. Still it is true that as many who enter this field thoroughly prepared by study and practice, reach the goal of their aims as in any other business or profession. From one to two thousand dollars are enough capital to invest in the business. This capital, rightly managed, is sure to give a return of from 100 to 150 per cent. One person can care for 100 colonies of bees, and not work hard for more than three months of the year; while with a competent assistant for three months in the year he can care for double the number. I think few apiarists of skill and experience would agree to sell the average product of each colony for \$15. We see then, that in the small amount of capital invested and the proceeds from the well managed apiary, apiculture takes high rank.

It is true that with a large apiary, the labor for May, June and July, and possibly for August and September, is really arduous; but when it is re-

membered that there are many ladies that successfully manage and care for quite large apiaries, we cannot doubt but that with wise management the labor may be reduced, so as not to be a grievous burden. Some of the ablest apiarists in our country are quite delicate women, who undertook apiculture to brace up declining health. In it they found health, money and pleasure, surely a worthy trio.

Many declaim against apiculture as an avocation. Only the specialist, say they, should keep bees. This would take from our ranks Dzierzon, Langstroth and many others of our first apiarists. One of our graduates who by profession is a preacher, wrote me a year ago that the proceeds of his bees exceeded his salary. Last year his honey brought even more; and this spring he sold \$1,150 worth of bees, and had 80 colonies remaining. Another graduate has a farm and also keeps bees. I asked him a few days since why he did not sell his bees, as he was speaking of too much work. "I had better sell my farm," he said, "as my bees pay the best."

Apropos of the above, it is said, that if one wishes to learn bee-keeping, he had better go to some large apiarist and let the college alone. Reason and statistics argue otherwise. Culture, or a well trained mind, wins in every race. Bee-keeping demands good judgment and trained observation. The college course tends to develop both. Many of our graduates are now keeping bees, and all with marked success. Four of these have a national reputation, and two are known in all bee-keeping countries.

For the American Bee Journal.

The Black Sage of California.

A. W. OSBURN.

On page 427, of the BEE JOURNAL, is an article taken from the California *Rural Press*, on "Honey Flora—White Sage." The writer cannot be as well posted about the honey-producing plants of California as he might be, or he would not have failed to give the black or button sage credit for what is justly its due. The two sages (white and black) stand in about the same relation to one another that the white clover and basswood do to one another. The nice white comb honey that goes on the market is called white clover honey, while in all localities where basswood is plenty, I do not think there is one ounce of white clover to every 10 pounds of basswood honey. So in California with the two kinds of sage, bees will not work on white sage on a range where the black sage grows. The latter yields honey in a much larger quantity than the former, and of a much finer quality, and yields all day, from daylight till dark; and I doubt if in the whole world better honey can be produced than comes from the black or button sage; clear as a crystal; almost white, with a good body, and in flavor it is impossible to get anything finer.

The white sage yields honey in the forenoon, but not much in the afternoon. It is thin when compared to that which comes from the black, and in color and flavor it does not rank in the same class with the former at all.

I know whereof I speak. I have seen the two grow on the same bee range, very many times, but not on the same ground. For the habits of the two plants are as unlike as need be. The black sage chooses the sides of mountains and foot hills. It can hardly, if ever, be found on flat land, but the highest peaks of the coast range of mountains in California, seldom get too high for the black sage to thrive and do well, and this is one of the best evidences of its superiority as a honey plant. It is a long and well-established fact, that the best honey producing plants grow on the highest land. The white sage is a lover of the bottom lands of the canyons, along the banks of streams, very rarely getting 200 yards from high water mark. It throws up a number of stalks from the root every spring, that bloom the same season, and then die. It does not resemble a bush or shrub, but has the appearance of a weed. It is a most profuse bloomer,—while the black sage is a bush, a shrub, with hard solid wood, hence the substantial foundation for the best honey in the world to come from. When there is plenty of rain the black sage blooms for six or eight weeks, yielding honey like but very few plants do yield, and of a quality that is XXX.

Water Valley, N. Y.

For the American Bee Journal.

The Season in Southeastern N. Y.

HOWARD T. BUSH.

I began the season with 41 colonies, spring count; it was very cold and wet all the spring. Apple bloom came the last of May. My bees gathered some honey from it, and about that time I transferred 23 colonies, and I fed them the waste honey that I obtained from those that I stimulated to brood-rearing. I worked them on Mr. Doolittle's plan, and when my honey harvest came, on June 6, my bees were very strong, but it was cold and wet. Raspberry bloomed on June 6, and my first swarm came out on the 9th, and I began to extract on the 15th; and from then until the first of July, I took off 1,000 pounds of honey (700 pounds of comb and 300 pounds of extracted). White clover came in bloom about June 10, but it was so very wet that the bees did not work on it. In the last week in June, sumac came, and I never saw such a bloom. The weather became clear, and I never saw bees gather honey so fast. On July 4, my bees began to kill the drones, and in one week you could not see a single drone. On July 15, basswood bloomed, but there is not enough here for bees to make any more than a living, and hardly that, so my bees have been idle from July 20 until about two weeks ago; then buckwheat bloomed.

About Aug. 1, it became very dry, and we have had no rain to speak of since; we have cold nights, so cold that bees cannot work until 8 a. m.; they work while the dew is on, and then lie still the rest of the day. We have had two frosts this week; the bees just about make a living. I shall not get a pound of buckwheat honey; goldenrod is coming in bloom, but if it stays dry, I shall get no honey from that source, so I think that my honey harvest is over for this season. I used two-pound, one-pound and half-pound sections. I sell two-pound and one-pound sections for 15 and 20 cents per pound, and half-pounds for 25 cents a pound, in my home market; and I get 10 cents for extracted. I have sold all of my half-pound sections but a few that I want to exhibit at our county fair, on the first of October. I mail a few bees from my apiary. I want to know what kind of bees they are. Are they the brown German or black bees? The queens are very large, about one-third larger than Italian queens.

Monticello, N. Y., Aug. 31, 1883.

[They are of the brown German race,—Ed.]

Read before the Maine Convention.

Profitable Pasturage for Bees.

ISAAC F. PLUMMEY.

By request of one of the members of this association, I have taken up this subject to give you a few thoughts on my experience and observation in regard to planting and cultivating flowers, trees, shrubs, etc., for artificial pasturage for bees.

I have not had great experience in this line, but I have had enough to know that to a certain extent it pays to plant for bees, and when we are planting fruit trees and small fruits, we should remember we shall some day reap a rich harvest of honey as well as a harvest of golden fruit, and thus reap two profits to pay for our labor. I believe, and have always thought that orcharding and the culture of small fruits should go hand in hand with bee-keeping for the reason of the honey which fruit trees will produce when they are in bloom. So let us greatly extend our orchards, and in a few years we shall see our bees getting more honey, and that we are getting more and better bee pasturage in our State.

There are but few farmers and bee-keepers in our State who have not more or less waste pieces of land around fence corners, roadsides and side hills; and what better purpose can such pieces of land be put to than by sowing them to sweet clover, which is one of the greatest honey-producing plants we have in this country, and how much better such pieces of land would look to the eye and at the same time have the bees gathering honey, the sweetest of all sweets from the flowers that such places will produce by a little of our time and care spent in such a noble purpose. Who says it will not pay? I for one say it will pay.

Another great honey-producing plant, and one that will hold in bloom from July to the first of September or October, is a plant called "borage." It has a blue flower, and is a very attractive flower for either field or garden culture, but it needs a deep rich soil in order to grow to perfection. I sowed some in my garden last spring. It came up well, made a very fine and rapid growth and bloomed finely. It was just remarkable to see how bees worked on it. Its flowers kept dropping and kept blossoming until the dry weather dried it all up, and I know it would have kept in bloom a number of weeks longer if it had not been for the drouth. I like to see the bees work so well on this plant, that I shall sow a lot another season, if nothing prevents.

Of the other honey-producing plants that are highly recommended, some of which I know by experience are very good for bees, and will pay to cultivate on a small scale. To go with bee forage may be mentioned the following: Catnip, motherwort, boneset, figwort, spider plant, mignonette, Chinese mustard, cleome, golden honey plant, etc. I think if we give this branch of our business the same attention we give to other branches of bee culture, we soon will see our bees gathering more honey, and if we get more honey we shall get more money out of our bees. Now let us try and see what we can do to advance bee-culture in our State, and if we can do so by planting for our bees, let us do it; and if we can do so by improving our hives and honey boxes, let us do so by all means, and I know by improving our bees and breeding them up to higher standard of excellence, and at the same time give them plenty of flowers from which to gather honey, that we must be successful in bee culture in this State and in all other States. I will bring this to a close by saying to Maine bee-keepers, plant largely of honey producing plants, and you will not be sorry for your time, pains and the pleasures it will give you, and the land that you will use for this purpose will be well improved.

For the American Bee Journal.

Bee-Keepers' Week at the Southern Exposition.

G. W. DEMAREE.

The Southern Exposition Company is composed of wealthy business men who, of course, know nothing of bee-culture. It was hardly to be expected that they would bestow special favors upon bee-keepers; hence, it became necessary to apply to the Agricultural department of our State for accommodations. The same course was pursued by the Horticultural Societies, and nobly did that department respond to our wishes. Prof. Todd, chief manager of the Agricultural department of the State of Kentucky, is a man of broad views, and so interested was he in our new (?) enterprise that he gave us special favors and attention. Had we known before

hand that our enterprise would have been so lightly favored by the managers of the Exposition, and so highly appreciated by the public, we would have gone prepared to surprise the "natives." As it was, our honey and bee show was a credit to Kentucky apiarists.

The table erected for our accommodation stood in a conspicuous place; was about 5 feet wide, and covered with snow white cloth, and was extended in length as needed. Much of the honey was displayed in fancy shape, but the greater part of it was plain, neat, and attractive, and beyond question was admired most of all. People are used to gaudily labeled tin cans, and beautifully colored confections, and have learned to know that the fancy outside gives no guaranty of the purity of the article within. It seemed to me that the tin cans of all sizes were a failure, especially the very small sizes. These were covered with exaggerations in the form of labels.

It was amusing to hear the remarks made by persons in the mighty crowds that gathered about the tables to see the Honey and Bee Show. "Them little tin cans look too much like salve boxes." "O! ain't that charming honey in those square glass jars." "Those tall glass goblets are beautiful." "Look at that comb honey; wonder if the bees made it in them cases." "La, if they hadn't got bees making honey right in the Exposition." "Wonder what them bees are making honey out of." "That's the queen is it? Well, now, where is the king?" "Won't they improve on honey before they are done experimenting?" This last remark was directed to me, and I answered: No, God makes pure honey, and the bees gather it from his ocean of flowers. Man makes glucose and calls it honey, and poisons his fellows for a few paltry dollars. These are the facts in a nut-shell.

Kentucky apiarists will not soon forget "Bee-Keepers' Week" at the great Southern Exposition. I would like to mention the names of the distinguished bee-keepers from many parts of the United States, who "hunted me up" to grasp my hand, during bee-keepers' week, but I could not do it without forgetting some whose memory is henceforth dear to me. I will be pardoned, however, for mentioning the name of W. S. Hart, of New Smyrna, Fla., because he came from the uttermost parts of the Union to visit us. Mr. Hart proposes to be at the Toronto Convention before he returns home. I am sure that all who meet him will not only find him a master in apiculture, but a most congenial friend and gentleman. The sessions of the Kentucky State Society were well attended, and the proceedings very entertaining. The assembly of bee-keepers was at no time very large, owing to the many things to attract at the Exposition, and from the further fact that many of the members of the society had to look after their honey and bees on exhibition. Still, Dr. Allen was heard to remark that it was the "best meeting ever held by the society."

I believe I learned something during "bee-keepers' week" about preparing honey for the market. I believe it a mistake to put flashy labels on small honey packages. It is too suggestive of the trashy goods so commonly seen in family groceries. These extravagancies have had their day, and people are getting tired of being cheated by outside appearances. The trade will have much more confidence in a plain label that gives the name of the article and the name and address of the producer.

At the honey show the competition for the first prize on comb honey was doubtless very sharp. I cannot see how it could have been otherwise, as so many fine combs so nearly alike were in the display. There was more difference, however, in the extracted. Extracted honey may be extra good, good, common and indifferent, just in proportion to the good management of the apiarist.

During the latter part of last June a neighbor of mine informed me that the "yellow bees" were working thick on his red clover. I visited the field and found my bees working busily on the red clover. Bees were gathering rapidly from the white clover at the same time. This led me to observe closely, and I believe that nine out of ten of the bees which were visiting the red clover were of the lightest strain of bees in my apiary. I thought but little about the matter at the time, as I had never got more than 20 pounds at two different times, heretofore, that I knew to be red clover honey, and this was in the comb, and gathered from the second crop of clover, and late in the season. In the former case the work was done on the red clover, in the best of the white clover harvest, and on the first crop of red clover bloom.

A short time after this I extracted some six or eight hundred pounds of the whitest and thickest honey I ever drew from the extractor. When I saw it was extra white, thick honey, I kept it by itself. From this lot of honey I made up my exhibit of extracted honey, and it took the first prize at the Exposition. Mr. Muth, of Cincinnati, sampled this honey, and expressed his belief that it was too white for white clover honey, and gave it as his opinion that it was red clover honey. I am able to identify at least 6 colonies that produced more or less of this remarkably white, thick honey. Although I have seen my bees working on red clover once in awhile, I have heretofore had but little faith in "red clover bees," and I yet suspect that the seasons must be extra good so as to fill the deep tubes of the clover blossoms pretty well with nectar in order that any bees yet imported to this country can reach it sufficiently to obtain surplus honey. Nevertheless these colonies will receive extra care for future experiment.

The Kentucky Bee-Keepers' Society has set on foot a scheme—if successful—which will be of much importance to those who contemplate making honey production a specialty. A committee has been appointed whose duty it will be to collect infor-

mation as to the unoccupied fields suitable to the production of honey in our State, and about everything relating to the adaptability of the State to the bee business. The work will be published in pamphlet form by the society. It is hoped that such a work will be of the greatest benefit to those persons seeking locations for apiaries. The work of the bee-keepers' societies of our country has heretofore been too circumscribed in character. Their proper sphere is too benefit mankind, and in order to do this they must not only be progressive but aggressive in their work. Committees appointed by societies generally do nothing, simply because nothing is expected of them. The fault is with the society. The committee selected for this work is composed of Dr. N. P. Allen, of Smith's Grove, Ky.; W. C. Pelham, of Maysville, Ky.; John T. Combley, of Napoleon, Ky., to which the president of the society was added. With the untiring energy of Dr. Allen at its head, this committee will discharge its duties faithfully.

We have quite a drouth here now, and the prospects for a fall run are not at all flattering at this writing. At the honey show at the Southern Exposition, Mr. A. C. Cunningham, of Salvisa, Ky., took first prize on comb honey, and N. P. Allen, of Smith's Grove, Ky., second prize. Your humble servant won first prize on extracted, and N. P. Allen the second.

How to Clean Wax.

F. L. DRESSER.

The great demand for comb foundation, and consequent consumption of wax in its manufacture, has so destituted the market that the bee-keeper now finds little trouble in realizing twice the price for his wax that he did a year or two ago. And the prospect is, that unless beeswax is imported to this country in considerable quantities, the price will rise still higher, and bee-keepers may, ere long, consider the question of running some colonies for wax as a prime object. But with the present prices and amount obtainable, the care of wax is a question of dollar and cents to those who wish to make bee-keeping pay. With many this is considered "the woman's job," and given no further thought by them; while the women dread this annual job as much as we do the semi-annual house cleaning. Indeed, I think that I should prefer to blister my hands pounding an old dusty carpet than to burn them raw pounding hot wax through an old coffee sack. I know that I would rather eat my dinner spread on a barrel in the woodshed than to have my clothing and uncovered extremities smeared with such immovable stuff. Yet, with a little expense and proper management, no one need be made uncomfortable, and the over-burdened farmer's wife may be released of the detested duty.

In the first place the bee-keeper should have a box handy into which to throw his old comb; that which is free from cocoons should be kept separate from the rest. If the millers commence their depredations, a little burning sulphur will disturb their feast and make you master.

Next a Swiss wax extractor should be provided (see engraving). For

Swiss Wax Extractor.

the sake of some who, perhaps, have not seen one of these instruments, I will attempt a brief description. It consists of a can divided a few inches from the bottom by a tin perforated with large holes near the circumference, and inclining from all directions toward a snout which protrudes from one side on a level with the tin. Above this hangs a basket made of perforated tin, so placed as to hang entirely within the holes punched in the dividing tin. The melting wax will then fall upon the tin and escape by the snout, and not leak through into the water tank below. Connect a tube from the outside with the water tank to enable you to refill the tank without removing the extractor from the stove. Cover the snout with a tight-fitting jacket open to the inside. This will prevent the wax from hardening in the snout, and save much trouble. Make a tight-fitting cover for the whole, and the thing is finished.

You will then want two or three Moulding cans, such as the figure below.

Moulding Can.

A is a frustum shaped can encased in the cylindrical can, b; c is a tube for filling b with water, and d, a faucet, is for emptying the can; e and f connect only with the outer vessel. Thus equipped, you are prepared for business. Select a day in the fall, after the bees are prepared for winter, and you have plenty of time. Drive the women out of the kitchen, and make it as comfortable for yourself as possible. Then prepare your extractor

by filling the water tank with water, and the wax basket with comb. Place a moulding can under the snout, allowing the wax to fall into it, at the same time having b filled with boiling hot water. When the can is full remove it, substituting another. Allow the wax to stand 4 or 5 minutes, then draw off the hot water and fill with cold water. As often as the water around the wax gets warm, replace it with that which is cold. The larger your extractor, and the more moulding cans you have the faster you can manipulate. When the cake is hard dump it out, and the can is ready to use again. The dirt will have settled to the bottom of the cake you have just taken; this you must cut off together with a generous slice of wax, so as to be sure you get it all. You can run the refuse over again and get the wax from that. The cakes are now in a convenient form for shipment, and should be sold in the early spring to some supply dealer. You can continue to get dirt from the wax as many times as you will run it through, but by running it through once it will all be prime yellow. Pure beeswax is pure white, and the slightest color is the sign of the presence of foreign matter; hence, if all the foreign matter be withdrawn the wax will be white. I have a further addition to the extractor by which I can prove my statement. A cake of the dirtiest, blackest wax that I ever saw was made white by this instrument, and it was not exposed to the sun nor any bleaching substance for a moment. But most of us are satisfied to have our wax all yellow and in convenient cakes, and this is the easiest method that I know, or of which I have ever heard.

Hillsdale, Mich., Sept. 1, 1883.

Putnam County, Ind. Convention.

The Putnam County Bee-Keepers' Association met Saturday, Aug. 18, at Greencastle. The attendance was not large, but it was enthusiastic. After the necessary business had been attended to, the different members reported the condition of their bees, and their prospects.

Mr. Tenant, of Greencastle, said that two years ago he started with but one colony. Since that time he had sold over \$100 worth of bees and honey, and had six stands left in strong condition, two of them with upper story full of honey. Mr. Homan, of Russell township, reported that his bees had done well, considering the wet weather in blooming time. He had taken 675 pounds of honey, and increased to 26 colonies. He stated that there were large numbers of bees in the woods. Mr. O'Neal stated that his bees were strong, and since honey harvest had been carrying honey from upper stories to brood-chambers. He had caught a stray swarm of bees, apparently full Italians. The president said he was more certain than ever that bees were profitable property, if properly handled. His bees had done well. He had sold several stands and quite a lot

of honey. The secretary remarked that he had taken some 800 or 900 pounds of honey, and had increased from 20 to 50 strong colonies with but 9 natural swarms. Had sold all his honey at from 20 to 35 cents. Others reported similar success. W. Mason gave an account of a visit to the apiary of W. Smith, of Johnson county, and stated that Mr. S. had sold \$500 worth of honey, and had 65 colonies of bees in chaff packed hives. Mr. S. told him his bees yielded a better income than his 160 acres of good farm land.

Our society meets the third Saturday of each month, the next meeting being Sept. 22.—*Indiana Farmer.*

For the American Bee Journal.

Bees in Shenandoah Valley, Va.

A. R. KOHNKE.

Having gone there, with the object of finding a better locality for bee-keeping than I have about Youngstown, O., I thought I would give to the bee-keeping public what I have seen and learned with reference to our pursuit.

Following the most urgent invitation of Mr. Jordan, of White Sulphur Springs, I went there the last week in July. Arriving at the Springs, which I made my headquarters, I received a most cordial welcome by Mr. E. C. Jordan, the proprietor. This gentleman has some 53 colonies of bees in Langstroth hives; but owing to his time and attention being required to look after the welfare and comfort of his guests, his bees are rather neglected. There are two springs on this place, a sulphur and an iron spring. I have met people who were broken down in health, not being able to obtain relief by any medical treatment, who had been almost entirely cured within a few months at these springs, which, if it proves anything, proves that that particular place is most conducive to health. Space does not permit me to describe that locality in detail, but Mr. Jordan will furnish very willingly any information in regard to it.

As to the bees, their main honey source is blue thistle, which, to judge by what I have seen, must be one of the best, if not the best honey plant this country produces. The honey from it, if not better, is surely equal to white clover; it being of the same color and consistency as the latter, but of a milder taste. Besides blue thistle, locust grows there in great abundance, as also the different kinds of berries, especially blackberries. But where blue thistle abounds white clover is scarce and *vice versa*.

One day Mr. Jordan and myself drove down to Berryville, about nine miles from the Springs, to visit some bee-keepers there. One of them, Mr. Diehl, who has been quite sick, hence not able to attend to his bees properly, has an apiary of about 200 colonies, blacks, Italians and Albinos. His crop was about 5,000 pounds of comb honey. Another gentleman, in the same town, had 90 blacks, hybrids and Italians, and Mr. Showers, also

of the same place, has about 40. Most of the surplus arrangement had been taken off the hives, in consequence of the honey season having closed, with a faint hope of obtaining some from iron weed, which is said to yield honey some years.

Some other day I went to Winchester, it being about five miles from the Springs, to see the following bee-keepers: Mr. Brown, Mr. Slagle and Mr. Gibbens; found none of the gentlemen at home on account of a picnic excursion, but had access to the largest apiary, kept by Mr. Gibbens, who makes a business of it. I was shown around by Mr. Gibbens' son, a very accommodating young gentleman. Mr. Gibbens works his bees in a very progressive manner. He has used this year, for the first time, the one-pound one-piece sections, using comb foundation starters of a triangular shape, one corner of which nearly touches the bottom of the section. The idea struck me, that comb foundation used in this shape, might keep the bees from building little bits of comb in between, as they have a better chance of clustering than where full sheets are furnished; besides that it would be a saving of foundation to the extent of one-half. I may give right here some more of my experience in my own apiary, and what I have seen in others.

The fact that bees need large quantities of honey to produce a small quantity of wax, has led to the invention of comb foundation machines and the use of comb foundation in brood-chambers as well as for comb honey. In order to save the honey. This may be best to some extent, when honey is not very abundant, but I rather question the expediency to give full sheets of comb foundation in sections for this reason: I have noticed that, when honey is coming in slowly, the bees will draw out heavy walled comb foundation a little; but when it is coming in fast, they do not touch that heavy wall, but build new comb on the foundation given. I used the heavy-walled foundation made on a Given press, and the light-walled made on a Vandervort machine. The light-walled was always drawn out, so that the comb foundation could not be noticed when cutting the comb, but with the other more or less "fish-bone" was left, very often the whole of it. Besides this, I found after the comb was finished, the bees had wax to spare, putting it here and there in little lumps in some empty corner, but especially on the glass at the ends or sides of the sections. For the use of full sheets of comb foundation in the brood-chamber, there are other and more important reasons than the saving of honey and wax in its construction, which I need not enumerate here, as they are too well known; but for sections, I think we can use less to our advantage, using such as can be made on a Vandervort machine only, as far as I know.

Now back to Mr. Gibbens' again. He also had taken most of his sections off the hives, leaving only a small part of those not yet finished, in hopes of obtaining some honey from iron

weed. On the whole, I think by what I have observed, that the Shenandoah Valley is a very good bee country, but, perhaps, no more so than many other localities where more fruit trees are cultivated, which are in great deficiency where I have been.

Youngstown, Ohio, August, 1883.

For the American Bee Journal.

Honey Crop, Marketing, etc.

B. T. DAVENPORT.

I have been much interested in reading the columns of your valuable paper this season, and especially the reports in regard to the present and prospective indications for honey. I like the idea suggested by Mr. Kendall, in last week's BEE JOURNAL, of having a barometer, or honey signal-service, a good one, providing we are careful not to exaggerate our reports, nor make out reports for the whole season at perhaps the very opening of clover, which, if the weather should be propitious, and the bloom as good as it was this season, are apt to be very flattering. It is well to be hopeful at all times, which, as far as I am acquainted, I believe is a peculiarity that bee-keepers have, but in our public reports, we want the facts, and opinions should be given as such only. We too frequently see an otherwise excellent report or letter with no date given, or if a honey report, the kind not mentioned, whether comb or extracted; such articles I mark down about 50 per cent. This was the coldest morning of the season—mercury 41°, but saw no frost. Bees have done fairly here, but too much wet and cool weather for a real good yield of honey. The most of our surplus was gathered during the latter part of June and first half of July from white clover; basswood bloomed considerable, but we obtained no honey from it; it rained nearly all the time it was in bloom, and were the heaviest rains known for years, doing considerable damage to hay that was cut, both in the stack and field. I have been working two apiaries this season, $5\frac{1}{2}$ miles apart. I began with 90 and now have 136 colonies, and have taken off 4,200 lbs. of honey in $1\frac{3}{4}$ lb. sections, all white, and think there is enough on the hives of mixed honey to make out about 6,000 lbs. This is probably one of the best locations for honey in the state. I found a drone in my Carley apiary (the one away from home), with one very red eye; I saw him twice, while looking through the hive. Auroraville, Wis., Sept. 5, 1883.

For the American Bee Journal.

Bee-Keeping in Utah.

JOHN DUNN.

Bees have not had the attention they should have this year. Some never use an extractor. One bee man told me, the other day, that he had not used one, although he has 6 colonies and is among the oldest hands at the business; but after I had shown

him what I had done with 2 colonies, he said he would get an extractor; but it was like the boy, as I told him, who bought a penny purse to put a half penny in; it was too late now, to get much benefit from the extractor.

Quite a feeling has been made against the use of the extractor, through the remarks of our assessor, who said that foul brood was caused by extractors, and where they were used, foul brood was sure to exist. I talked with him on this subject, and asked him for his proof. Why, said he, I have read it in a book; but when questioned in what book, he said he could not tell where, so I told him to come and I would show him, where larvae was pulled out, that the bees would put it back, when put in the hive; but I would not advise any one to extract from sections that had much brood in them.

I have extracted about 50 gallons of honey from 10 colonies up to date—increased to 20 this season, and if I had got my sections full of comb, I could have done better. I have used a good deal of foundation.

We should have a good flow of honey; almost every one has an orchard, and own their own house and garden lot, and since the new fence law was passed, almost every one has a patch of clover and lucern, and in the spring, if you take a walk out in the country, you will see the wild flowers, and in the fall, they shine with splendor.

I think that many would keep bees if they were not so fond of stinging, but it is the only thing they have to defend themselves with, and it is a wise provision, for, if it was not so, the poor bees would be abused many times just for fancy. I found spear mint a good thing to rub over the hands; they do not like the smell. I did intend to have 1,000 lbs. of extracted honey this season, and I do not know yet but I may get it. Bees work now on clover, squash, lucern and other plants, and are doing splendidly, so far as I have found out in this country.

Toele City, Utah, Aug. 15, 1883.

For the American Bee Journal.

Cyprian and Syrian Bees.

E. F. CARROLL.

The anathamas hurled against the Cyprian bees by many who have not thoroughly tested them will cause many apiarists to dispose of their Cyprians before they find out their good qualities.

It is true that the Cyprian bee is a little warlike if not thoroughly understood. I have handled these bees for three years, and find them superior to the Italians in every respect. First, they are more prolific, and hence have their hives always full of bees, and when you have the bees, you can have the honey if there is any to be had.

Secondly, they defend their hives better; it being almost impossible for a strong colony of Cyprians to be

over-powered and robbed by other bees.

Thirdly, when the extractor is used they are far superior to the Italians by being so easily shaken and brushed from the combs.

Fourthly, they fly faster and further for stores, and have a longer tongue than Italians or blacks, and they work well on the cotton, and this feature alone ought to bring them into favor with the bee-keepers of the South; and

Lastly, the sun never gets too hot for them; I have seen them this year, when the thermometer was at 104° F. in the shade, working right along, as if it was spring-like weather, and my 3 colonies of Italians and one black colony were not even showing a desire to do anything but bring in a little water, and very little of that.

I have one of G. M. Doolittle's best Italian colonies. The bees are perfect beauties, and as gentle as pet chickens, and I have a host of Cyprian colonies just as gentle, and I handle without smoke or gloves.

I have about 25 colonies of Holy Land bees, and as this is my first year to give these a thorough test, I am satisfied they are almost identical with the Cyprians, and their temper is not quite so high strung. There is no doubt they will stand the test. I see some grand reports coming in from these bees from different parts of our broad domain, and it is only a question of time when these bees will be the favorites with American bee-keepers.

Dresden, Texas, Sept. 1, 1883.

Prairie Farmer.

Apiary Talks—Seasonable Hints.

MRS. L. HARRISON.

It is well to observe closely during the honey season, and ascertain from what source the supply is obtained. Where I am "rusticating," in Connecticut, near the sea-shore (Aug. 21), boneset or motherwort, goldenrod, and a species of wild touch-me-not are in bloom, and bees are apparently doing well. For several days it has been showery, and the sun comes out very hot, and the nights are warm, insuring the right condition for the secretion of nectar. Where the early potatoes were raised, Polygonum will soon be blooming. The sweet clovers (*melilot*) of the white and yellow varieties, are now ripening their seed, and it should be gathered and scattered in waste places. I saw, lately, the yellow variety which is sometimes called Bokhara clover, growing around the edge of a salt meadow and on rocky ledges. Though it is not a bad weed, it will hold its own when it has gained a foothold.

In most Western and Northern localities, the three or four weeks preceding frost bring on flowers which often afford the very best pasturage of the year. During this late honey flow, encouragement should be given to the rearing of brood, so that there may be plenty of young bees to go into winter quarters. Sometimes

the brood-nest is almost filled with honey, and the queen cannot find a cell in which to lay; a part of the combs should be extracted and returned. Sometimes this fails to insure brood-rearing, as we have found such combs in a few days (during a big flow) to have every cell glistening with honey. We lose our bees the coming winter, "charm we ever so wisely," but we will stand a much greater chance of preserving them if we look well to them now. Some colonies, although prosperous the past season, have queens whose usefulness has departed, and who are decrepit with old age, and should be superseded with a young vigorous one, able to withstand wintry blasts. All after-swarms have young queens, and if they are too small to winter, they might be wintered with an old stock, by first removing the old queen. Colonies that are found to be queenless, or have done laying queens, should have queens given them or united.

Many people complain of moths destroying their bees, when they only moved in when the house was empty, from defect or loss of queen.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Bees Balling their Queen.

Will James Heddon please inform me why my bees balled a virgin queen about 12 days old; also, why they balled a dollar queen, which I introduced about 6 weeks ago, and was laying nicely ever since, and was laying when they balled her? They started queen-cells at the same hive. I took her out and put her in a nucleus, and she was laying the next day.

RICHARD GRINSELL.

Baden, Mo., Aug., 27, 1883.

ANSWER.—Bees ball strange queens and queens that for any cause (and some causes are as yet unknown) they are jealous of. Why they should have been entertaining a "sidewise" feeling toward your 12-days old virgin queen, I do not know enough about the minor circumstances to tell. Perhaps because she was aiming at becoming a wrinkled, cross old maid. Workers are quite often suspicious of introduced fertile queens for many days after they begin to lay, and often pounce upon and kill them upon the least provocation, such as opening the hive, when if they had been left undisturbed, they would have acted like dutiful children. I should think a week time enough to lay aside all this jealousy. I have found that to suffice as a rule. I have had colonies

ball their queens on opening the hive; queens that were mothers to every bee in the hive. I have never known a case of the kind, but what the colony was in some way slightly out of perfectly normal condition; a little spring sickness, or clipped queen, or something of the sort.

Wide Frames.

In a recent number of your JOURNAL Mr. Heddon says the wide frames are being superseded. Will he be kind enough to tell us by what, with details sufficient to enable a man of ordinary understanding (not a mechanic) to make them for trial.

RUSTICUS.

ANSWER.—The broad frames are, with many of our leading and recognized most intelligent apiarists, being laid aside for the case system. I cannot, in this space, fully describe the case that I use and prefer, but I will say that the broad frame supers differ from the cases, inasmuch as that the cases, instead of taking frames at all, receive the sections between partitions, without the use of frames or separators. I will refer you to cut Fig. 1, Sec. D, page 659, BEE JOURNAL for 1882.

SELECTIONS FROM OUR LETTER BOX

The Fall Crop.

Bees are storing honey a few hours in the middle of the day. The heart-ease and goldenrod bloom is abundant, but the weather is too dry, and the nights too cool, for a large flow of honey. A good rain and warm weather would give us a heavy flow. The honey crop in this part of the State is not a heavy one, although in a few localities, where strict attention has been given, a fair crop will be secured.

REUBEN HAVENS.

Onarga, Ill., Sept. 4, 1883.

Horse Balm Honey.

Enclosed find a plant for name. I have exhausted my botanical resources without being able to name it. Bees work on it freely, and it undoubtedly yields a large amount of honey. I have a suspicion that the honey is bitter. The plant grows in rich woods. It is not very abundant.

M. MAHIN.

New Castle, Ind., Aug. 28, 1883.

[The plant is the widely disseminated Horse Balm (*Collinsia Canadensis*). It is hardly possible that the honey is bitter. The plant belongs to one of the most important families (*Labiatae*) of honey producers, and is itself pleasantly aromatic.—T. J. B.]

Bees Working on the Spanish Needle.

In the spring of 1883, I had 40 colonies of bees, all Italians but 3. I did not get any clover honey, but got about 600 pounds of linden honey, and increased to 72 colonies. I have not obtained any honey since Aug. 1, though the bees are doing well now, on Spanish needle and buckwheat.

WM. T. SCOTT.

Mill Grove, Mo., Sept. 4, 1883.

Sand Wasps.

I send you a hornet that I saw with a fly in its fore feet. I never saw one like it before. Please say what it is, through the BEE JOURNAL.

J. M. HIBBARD, JR.

Athens, Ohio, Aug. 10, 1883.

[The large insect found holding in its forefeet a bee, is one of the sand wasps (*Pompilidae*), which store their nests with insects, to be used as food by the young. Usually a single species of insect or spider is selected by each kind of wasp, but I am not aware that this or any other wasp stores its nest exclusively with honey bees. The most remarkable thing about their method of hunting is that the wasp stings the prey in a particular nerve centre, in such manner that the captured insect is rendered entirely helpless, but is not killed. In this condition it is packed with others in a hole dug in the ground, accompanied by several eggs of the wasp. When these eggs hatch the young find in the stung insects food still perfectly fresh, because alive, but entirely at their mercy.]

Along with the above, in the box, was a dog-day cicada (*Cicada canicularis*). It is much like the 17-year "locust," but appears every year. It is quite harmless, except that it bores twigs of trees to deposit its eggs; as soon as hatched the larvæ enter the ground and live on the roots of plants.—T. J. BURRILL, Champaign, Ill.]

Bee-Keeping in Minnesota.

As I am sending for 100 copies of "Honey as Food and Medicine," I will report something of what my bees are doing, and it is a big report for Minnesota, but not in the least over-drawn. My account shows 317 pails of honey. These pails will hold from 15 to 18 pounds each, making in all about 4,755 pounds of extracted, and I have besides 1,624 pounds of beautiful comb honey. This amounts to 6,379 pounds without taking into account the strainings from the uncapped, which would average a pailful a day. I began the season with 32 strong colonies, and kept them warm and well fed during the spring. I now have 90 splendid colonies, 40 of which were not looked through during or since basswood bloom. There are

12 with boxes on that have some sections completed, 2 that have the entire 12 two-pound sections nearly full. I have some colonies that have not swarmed this season. I have a record of 3, 4, 5, 6 and even 7 swarms from one colony. The one giving 6, its first swarm cast three, one of which went into another hive and was killed; but I saved two, making an increase of 8 from that colony. I had combs for all increase. J. E. CADY. Medford, Minn., Aug. 31, 1883.

Syrphus Flies, etc.

Enclosed find three flies and a bee. 1. I found the flies hovering around the hives, evidently persuaded in their own minds that, if they had their rights, they ought to live there. The bees did not appear to mind them much. What are they?

2. Of what race is the bee enclosed? I am often puzzled about these stripes. How many stripes has this bee? My bees should be Italians, but I see every once in a while the 15th amendment to the constitution there.

R. J. KENDALL.

Austin, Texas, Aug. 26, 1883.

[The insects are the prettily-banded, useful *Syrphus* flies, whose larvæ prey upon plant lice. They do the bees no harm.—T. J. B.]

After a bee is dead and "mashed up" in a letter, it is hard to tell much about it. If it had "stripes" they are not discernible now.—ED.]

Borage as a Good Honey Plant.

You may put down borage as an extra good honey plant. It commences to bloom in June and keeps up till the hard frosts. My bees have worked at it unceasingly since basswood harvest closed, and are still at it. Last year it was green until the end of October. It is very hardy, and is a perfect weed when it once gets into a garden.

C. W. YOUNG.

Stratford, Ont., Sept. 6, 1883.

A Worker in a Queen-Cell.

The JOURNAL is a welcome visitor to our home every week, and while perusing its columns, last night, I found an experience somewhat like one I had not long since. I have reference to a "Curious Freak of Bees," by A. Rickenbacher, on page 433 of the BEE JOURNAL. A few days ago I had a nice lot of queen-cells that I thought would hatch in a day or two. I lifted them out in the sunshine to see how nearly ready they were to hatch, and to my surprise several had already emerged from the cells, and were walking around on the comb. I cut out all the cells that were not uncapped, and when I had put one in each hive or nucleus that I had prepared, there was one left. I cut it open, and found in it a worker bee in the prime of life. I think that worker bee crawled into the cell just when the queen got out; the cap not being cut clear off, sprung shut, and the bees sealed it.

A. R. NISBET.

Dobyville, Ark., Sept. 1, 1883.

Honey Already Candied.

I send you a sample of my honey. It has all candied or turned to sugar. Will you please tell me, in the BEE JOURNAL, why it candied so, and can I winter my bees on it? I started last spring with one colony of bees; the bees swarmed three times, and the four colonies have gathered about 300 lbs. of honey in the boxes, and body of the hive, and it is all candied or turned to sugar. Will the bees winter on a syrup made by melting up the outside combs, adding a little water and skimming off the wax? Other bee-keepers living near here, are complaining of their honey candying, like mine. E. HAMILTON.

Centre Conway, N. H., Sept. 4, 1883.

[Some honey will "candy" much more readily than that gathered from other kinds of bloom. Linden honey candies very quickly after being removed from the hives. You do not say what it was gathered from, but it is evidently caused by the peculiar flowers from which it came. You can use it for wintering, either as it is, or by making it into a syrup, as you suggest.—ED.]

Good Honey Harvest in Maine.

Bees have done uncommonly well in Maine, this year. I have one swarm that came out in June that has gathered 135 pounds of honey, mostly in one-pound sections. I am 77 years old.

LUCIAN FRENCH.

Dexter, Maine, Aug. 30, 1883.

Queens with Scarlet Wings.

I discovered a new kind of queen (to me) in the last part of May. I took the same queen and inserted it in a colony of bees, and the colony swarmed twice, and I received 175 pounds of honey from each. I think that these queens are more profitable than Italian queens. I think that I will transform my whole apiary with these bees; the queens have three yellow stripes, and their wings are scarlet. Please give me some information about the same.

PROF. HUGO SONTAG.

Cucamonga, Cal., Aug. 31, 1883.

[It is evidently another "case of sporting," many of which have heretofore been reported in the BEE JOURNAL. The regulation "bands" show them to be Italians.—ED.]

A Short Crop.

The crop of honey from this section is very short. Basswood was a failure. A colony weighing 63½ lbs. of bees, gathered but 15 lbs. during basswood bloom. The fall crop, so extraordinary last season in the flow, is about as extraordinary the other way, this season. "In a good season every bean-pole sweats honey, but in a bad one, no flower secrets any;" so said our German friends across the water; and the two seasons have made the demonstration here.

JESSE OREN.

La Porte City, Iowa, Sept. 5, 1883.

Trial Trip—25 Cents.

Special Notice.—We will, hereafter, supply the **Weekly BEE JOURNAL** for one year, and the seventh edition of Prof. Cook's Manual of the Apiary, bound in fine cloth, for **\$2.75**, or the **Monthly Bee Journal**, and the **Manual** in cloth for **\$1.75**. As this offer will soon be withdrawn, those who desire it should send for the book *at once*.

Bingham Smoker Corner.

Large Smokers need wide shields. Bingham's have them, and springs that do not rust and break, and bellows that sparks and smoke do not enter. The Conqueror has all improvements made to date, and a 3x7 inch stove, and 5x7 inch bellows. Sent post-paid for \$1.75. Address,

BINGHAM & HETHERINGTON,
Abronita Mich.

CYPRIANS CONQUERED.—All summer long it has been "which and tother" with me and the Cyprian colony of bees I have—but at last I am "boss."—Bingham's "Conqueror Smoker" did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham.

G. M. DOOLITTLE,
Borodino, N. Y.,
Aug. 15, 1882.

EXCELLING ALL.—Messrs. Bingham & Hetherington, Dear Sirs:—I am now selling your Smokers almost exclusively. You are excelling yourselves in smokers all the time.

Respectfully,
J. G. TAYLOR, Patented, 1878.
Austin, Texas, May 10, 1883.

THE VERY BEST.—The Bingham "Conqueror" Smoker is the very best thing I have tried in this line.
M. M. LINDSAY.
Fulton, Tenn., July 24, 1883.

During the following three months, Bingham Smokers will be sent post-paid, per mail, on receipt of the following prices:

The "Doctor", (wide shield)—3½ in. fire tube, \$2.00
The Conqueror (wide shield)—3 in. fire tube, 1.75
Large (wide shield)—2½ in. fire tube, 1.50
Extra (wide shield)—2 in. fire tube, 1.25
Plain (narrow shield)—2 in. fire tube, 1.00
Little Wonder, (narrow shield)—1¾ in. fire tube, .65
Bingham & Hetherington Uncapping Knife, 1.15

With thanks for letters of encouragement, and the absence of complaining ones, we tender to our thirty-five thousand patrons our best wishes.
Very Respectfully Yours,

BINGHAM & HETHERINGTON,
Abronita, Mich., June 1, 1883.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quimby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

**The Original
BINGHAM
Bee Smoker**

Books at Fairs.—Those who make an exhibit at Fairs will find that an assortment of Books and Pamphlets would sell and leave them a profit for handling. We will send such, postage prepaid, at 25 per cent. discount; or if the purchaser pays express charges, we will supply any of our own publications at 40 per cent. discount.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents. for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

The new two cent rate of postage for letters goes into effect on October 1. Three cent postage stamps will then be but little used. For all fractions of a dollar sent to us hereafter we should prefer either one-cent, or else five or ten-cent postage stamps. Do not send coins in any letter.

Fairs.—To any one exhibiting at Fairs, we will send samples of the BEE JOURNAL and a colored Poster, to aid in getting up a club. The Premiums we offer will pay them for so doing. For a club of 8 subscribers to the Monthly BEE JOURNAL, or 4 Weekly, we will present Dzierzon's Rational Bee-Keeping, price \$2.00.

Do not let your numbers of the BEE JOURNAL for 1883 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey at Fairs, will sell almost a fabulous quantity of it.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

37A1Y

SELLING OUT all the Black Queens by mail \$2.00 each, with 1 lb. bees, by express, \$1.00. Hybrid Queen by mail, 50c.; with 1 lb. bees by express, \$1.25. Italian Queen, \$1.00 by mail.
E. S. HILDEMAN, Ashippun, Dodge Co., Wis.

BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS C. NEWMAN.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most honey in its best and most attractive condition.

Appreciative Notices.

A neat and beautifully illustrated hand-book of apiculture.—American Agriculturist, N. Y.

Its chapter on marketing honey is worth many times its cost.—Citizen, Pulaski, Tenn.

Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of every beginner with bees.—News, Keitsburg, Ill.

Valuable for all who are interested in the care and management of bees.—Dem., Allegan, Mich.

Engravings are fine. Gotten up in the best style, and is cheap at the price.—Farmer, Cleveland, O.

Carefully prepared for beginners.—Farmers' Cabinet, Auherst, N. H.

A very valuable work to those engaged in bee-raising.—News, Prairie City, Iowa.

We advise all who keep bees to send for this excellent work.—Journal, Louisiana, Mo.

Carefully prepared, and of vast importance to bee-raisers.—Iodanian, Clinton, Ind.

New and valuable, and embellished with 109 beautiful engravings.—Democrat, Salem, Ind.

Much, practical useful information, in a cheap form.—Daily Standard, New Bedford, Mass.

The most perfect work for the price ever yet produced on the subject of bee-culture.—Anti-Monopolist, Lebanon, Mo.

A manual, containing all the newest discoveries in the management of these little workers.—Plain Dealer, St. Lawrence, N. Y.

Full of practical instruction, that no one who contemplates keeping bees can do without.—Farmers' Journal, Louisville, Ky.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.

It embraces every subject that can interest the beginner in bee-culture. The engravings perfectly illustrate the text.—Farm and Fireside, Springfield, O.

Embraces every subject of interest in the apiary, giving very thorough details of the management and manipulations necessary to make bee-keeping a success.—Farm, Longmont, Colo.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

Describes all the newest discoveries in the art, by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive shape.—Signal, Napoleon, O.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive shape. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—Farmer, Lancaster, Pa.

PRICE—Bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

THOMAS C. NEWMAN,

925 W. Madison St., Chicago, Ill.

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Bee and Honey Show at Toledo, O.

As we promised a year ago to attend the above Exhibition, and our health improving some, we concluded to go—the “change,” and meeting with companions and friends, with a subsequent visit of a few days to friends in Ohio, inviting us to brave the journey.

At Toledo we met a host of friends, among whom were Dr. A. B. Mason, Mr. C. F. Muth, Hon. I. N. Cotton, Messrs. Aaron Benedict, H. H. Overmeyer, C. H. Christiancy, P. H. Puhl, Dr. H. Besse, A. Gander, A. I. Root, H. B. Harrington, E. E. Hasty, J. Forncrook, and J. F. Hart, of Florida, and a host of others whose names we cannot now recall from Ohio, Indiana, Michigan and five other States.

The Fair was good, and the exhibit of bees, honey, wax and apianian supplies all that could be wished.

The Convention of bee men was enthusiastic and interesting. As the secretary will give a report of these sessions, we will not forestall that report, but will simply state that a more enthusiastic set of men we have seldom met.

Altogether, the Bee and Honey Show of the Tri-State Fair will be an “educator” of the people of the surrounding country, which will tell on the consumption of honey, for a long time to come, and greatly aid in the development of the honey market.

Do not let your numbers of the BEE JOURNAL for 1883 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference

Baltimore Bee and Honey Show.

In the Baltimore *Sun* of Sept. 7, we notice the following concerning the honey exhibit at the Fair at Baltimore, Md.:

One of the most attractive exhibits at the Fair is the apiary, in charge of Mr. Charles H. Lake, proprietor of the Sunny-Side apiary, on Greenmount avenue. Mr. Lake has on exhibition a lot of fine Italian bees in glass cases or frames, showing the bees at work and the movements of the queen bees, which attract much attention. He has also on exhibition a hive of bees which were allowed the free use of the grounds, and the owner handles them with all the freedom of pet canaries. He has receptacles for honey in the shape of hearts, shields and stars, and has trained the bees to fill them so as to make novel ornaments for the table.

The Commercial *Advertiser* remarks as follows:

The apiary, in charge of Mr. Chas. H. Lake, had many visitors, however, in spite of the bees flying about. The ingenious idea of making the cells for the bees was illustrated there. Sheets of wax were passed between two rollers, and came out with the cells already designed. The bees were all of the Italian variety. In one hive the swarm was free. The glass cases of another were placed upon separate stands, and all the processes in the life-history of the bee could be seen. The queen, easily recognized from her large size, was industriously depositing eggs in some of the cells; working bees were preparing other cells for eggs. Some of the young bees, having passed from the larvæ state, were gradually working their way out of the cells in which they had been imprisoned, fed in the meanwhile by the workers. From one hive of the bees 245 pounds of honey have been obtained in a single season.

This is the way to aid the sale and consumption of honey. There is nothing like attractive exhibits to call attention to the honey.

To give away a copy of “Honey as Food and Medicine” to every one who buys a package of honey at Fairs, will sell almost a fabulous quantity of it.

Honey-Producing Plants.

Prof. A. J. Cook, in the *Rural New Yorker*, when advocating the advantages to be derived from planting for honey bloom, says:

There is probably no subject in which the bee-keepers of to-day should take a deeper interest than this one. Honey plants are capricious, and only give up the precious nectar at such times as dame nature's mood is agreeable to them. Let it be too wet, too dry, or too cold, and the flowers yield not one drop of the coveted sweets. We see then, that a constant succession of honey plants, from the time of the opening of the willows and maples in April, till the frost licks up the last honied secretion from the asters and the golden rods, will not only yield greater profits every year, but often such a succession is absolutely essential to any success.

The Illinois State Fair will be held in Chicago Sept. 24 to 29. Indications are that this year's Fair will eclipse all preceding ones. Almost all the railroads will bring passengers at 1½ rates. We hope there will be a large Bee and Honey Show there.

It is a fact that glucose will kill bees if you attempt to winter them upon it, either in liquid form mixed with honey, or sugar syrup, or in the form of candy.—*Planters' Journal*.

The Editor of the BEE JOURNAL being unable to attend the National Convention, it will be represented by the Rev. W. F. Clarke, of Guelph, Ont., who is duly authorized to take subscriptions and orders for any of our publications.

An English paper says that “Mr. Firth, a Radical member of Parliament, is the largest bee-master in England. He is the owner of from 80,000 to 100,000 bees.” As that is only about two good colonies, we expect there is a “huge joke” somewhere about that ambiguous announcement.

Essentials in Wintering Bees.

Some time since we noticed the fact that J. B. LaMontague, Esq., of Quebec, had published a book in French, on Bee-Keeping. The following is a translation of what he has to say on wintering bees :

If there be an important subject full of interest to the bee-keeper, it certainly is that of wintering. We have seen whole apiaries, and the best prospects disappear in a single rigorous winter.

It concerns us then to consider this question attentively, and to adopt some method which may diminish if not to cause wholly to disappear the numerous losses, to which we are subject every year. The bee-keeper who succeeds in wintering must keep none but strong colonies, and a good colony in the fall should have at least four frames literally covered with bees. I do not mean that you should destroy weak colonies, for that is a ruinous position as I have elsewhere shown. The latter have not enough young bees, and consume relatively more honey than strong colonies. Are also wintered with difficulty, and when they survive are liable to be robbed in the spring. It is well to unite weak colonies in the autumn, if not before done. As to populous colonies which have not sufficient honey (which may happen from drouth), the bee-keeper should, before taking them in, feed them by means of a bee-feeder. Schuch's bee-feeder is a simple little trough in compartments 12 inches long, and is adapted to the opening so as to permit the access of bees from within and exclude them from without. You can use waste honey, maple sugar, or syrup made from sugar, but not molasses. Sugar of the country, which is soft, sown and placed in empty frames, will answer the same purpose, but be on your guard, and do not feed them with inferior sugar, such as glucose or corn sugar.

Each colony ought to have from 25 to 30 pounds of sound honey, that is to say, capped over, the combs of which the cells are not closed over in the fall contain unsound honey, unfavorable for wintering—these should be emptied with an extractor, and replaced by combs firmly capped over. All the colonies should be taken into the cellar in the month of November, or by the beginning of December, at the latest, if the season be mild, which cellar should be dry and perfectly dark; keep up a temperature from 45° to 50° Fah. Dry and dark cellars are those in general use in the houses of the farmers, and are in general very favorable to the wintering of colonies.

It is also necessary to create an air current at the top of the hives by means of openings, or of absorbents, which may draw off the excess of moisture without at the same time, causing a current of air which would prove fatal to the bees. Bees emit during the winter an enormous quantity of watery vapor, which, if it do not find an outlet, penetrates the

honey, renders it acid, and causes that fatal disease, dysentery—6 or 8 inches of straw placed directly upon the comb frames are a sufficient absorbent, or you can obtain the same result with sawdust. Some cry out against the ventilation of hives, relying upon the fact that they always winter with success without giving ventilation to their hives. It is possible that they then succeed in a cellar exceedingly dry, and where there is not the least moisture, but such conditions are seldom met with, and we affirm that ventilation is an essential thing to successful wintering. If you have no cellar, you can winter your colonies in a cool and dark room where there is a temperature from 40° to 50° Fah., but you must then give greater ventilation to the hives. You should not confine the bees in their hives by closing the openings by means of wire cloth, unless you winter them in the house. One would at first sight be led to believe that bees would be more at ease in a warm, than in a cool place, but the fact is otherwise, and one will lose many more by a high temperature than in a low one. I have already had proof of that fact. Thus it is necessary as far as possible to winter your colonies in cellars, combining the conditions before mentioned. It is better to put you hives in winter quarters early than late, in a dry time than in a wet, and when they are placed disturb them the least possible.

Overstocking a Locality.

Mr. G. W. Neihardt writes as follows to the Bee-Keepers' *Guide* on this subject :

Much has been written by eminent bee-keepers on the subject of overstocking any locality with bees, some holding that any place capable of sustaining a few colonies, is also capable of supplying a large number; others claiming that a field is capable of furnishing only a sufficiency for a definite and limited number. I am not able definitely to settle this question to my entire satisfaction, yet I must confess that my inability to secure such unprecedented yields of honey in "poor" seasons as that secured by Mr. Doolittle and others, forces me to conclude location has much to do with the profits arising from the keeping of bees.

A locality where only one or two honey-producing plants are the sole reliance for surplus, would certainly be an unsafe one in which to attempt to raise honey as a money-making business. White clover, which is the main reliance in many sections, is liable to be "winter-killed," or the drouth to cut it short, or wet weather to wash the nectar out of it. Fruit bloom is seldom so abundant as to furnish more than an aid to breeding, while the autumn flowers are very uncertain, and likely to be cut off by early frosts.

Cool weather very frequently prevents the storing of much honey in supers from late pasturage. It is, therefore, of the highest importance

to those desiring to engage in bee-culture for profit, to look well to the honey supply in the place they locate. The more diversified and abundant the honey-producing plants, the better the location. Where, however, several of these are to be definitely depended on, the rest may be supplied by cultivating such plants as produce honey in abundance.

It should not be a matter of doubt to apiarists, whether it pays to cultivate any plant for honey alone. Experiments should be made, and that subject settled definitely. If half the time and talent that is now expended in experimenting with hives, bees, and manipulations of bees, were expended in the production of honey-producing plants, there would be less complaint of dysentery, hard winters and unprofitable seasons. The honey supply should not be made a matter of luck any more than the other matters pertaining to bees, only so far as it should be beyond the bee-keepers' control to furnish it. Any locality almost could be made a good one. Whether, however, sufficiently so as to make it repay all the cost, experience alone can tell.

The next meeting of the Tuscarawas Valley Bee-Keepers' Association will be held at Newcomers-town, Ohio, on Wednesday, Sept. 26, commencing at 10 a. m. All interested are cordially invited to come and bring anything for exhibition that will interest bee-keepers.

J. A. BUCKLEW, Pres.
Clarks, Ohio.

HERBERT DENMAN, Sec.
Coshocton, Ohio.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

The quarterly meeting of the Marshall County Bee-Keepers' Association, will be held at the Court House, in Marshalltown, Iowa, on Saturday, Oct. 6, at 10.30 A. M. Subject for discussion, "Fall and Winter Care." All interested, in this and adjoining counties, are invited, for we hope to have a good meeting, and one of benefit to all.

J. W. SANDERS, Sec.
Le Grand, Iowa.

Look not mournfully into the past—it comes not back again; wisely improve the present, it is thine; go forth to meet the shadowy future without fear, and with a manly heart.—*Longfellow.*

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Fertile Workers.

We extract the following from the *Indiana Farmer* on the cause and cure for these pests:

Bees should never be allowed to go any length of time without a queen, or without eggs or brood from which to raise one in case their queen gets lost while on her bridal trip. Colonies that have been queenless for any length of time are very apt to contain fertile workers. The evidence that these pests are present, will be found in the promiscuous manner in which the eggs are scattered around in the comb, sometimes one, but oftener three or four in each cell. The bees will cap the brood over, but the cap-pings will be convex as other drone brood is. They will even build queen cells over the brood, but the eggs will produce only drones. There is no way of distinguishing these fertile workers from any of the others, unless you should see them in the act of laying, and should you destroy one or two there is likely to be a half dozen others left in the hive. A colony containing fertile workers will neither accept a queen if given them, nor raise one for themselves if brood is given them for that purpose. It is generally better to double up a colony in this condition with one containing a fertile queen. If the frames be taken some distance from the hive, and all the bees be shaken off on the ground, the most of them will go back to the old stand, leaving the fertile workers on the ground, when if a frame of brood is given them they will raise a queen. A better plan is to crowd the bees on as few frames as possible on one side of the hive, and close up with a division board. On the opposite side of the board hang two or three frames of brood and bees from another colony, and a queen if you have one. They will soon discover the better condition of things on the other side, and quickly unite with them.

Plan and Foresight of Bees.

Prof. A. J. Cook, of the Michigan Agricultural College, has this in a late number of the *New York Tribune* on the above topic:

The phenomenon of bees swarming is well understood. Most of the worker bees rush out of the hive sometime between 8 a. m. and 4 p. m.—usually from 10 a. m. to 12 m.—circle about in the air for some time, apparently waiting for the queen, which seldom leaves the hive till the bees are well out, and then all alight in a dense cluster on some bush, tree, or other support. If the queen refuses to leave the hive to join the bees, or if from defective wings she is unable to join them, they soon break ranks and return to the hive. After a space varying from half an hour to two hours—I have known swarms to remain clustered all night—the bees take wing and fly rapidly in a straight

line to the new home. This is certain, as bees have often been followed in a bee-line to the adopted home. Others have been followed for a long distance, always in a right line, when the chase had to be abandoned. Two interesting questions arise: Why do bees cluster? and How do they know of the home toward which they always take a bee-line?

It has been argued that bees cluster that scouts may go in quest of the prospective home. It is also more than probable that the queen, whose organs of flight—muscles and wings which she moves—have long been inactive, possibly for more than a year, may need this rest after her brief flight from the hive, before the longer one, which may reach a distance of miles. This view is strengthened by the not uncommon occurrence of bees resting midway on their flight after flying a mile or more toward the new home. I have known several cases where bees have thus clustered apparently for the queen to rest, after flying a mile or more. This home must have been sought out either before the bees left the hive to swarm, or else while the bees were clustered. A few cases are given by European bee-keepers where a few bees have been observed about a house or tree, going in and out of some small aperture, then leaving. The next day, or possibly the next day but one, a full swarm would take possession of the pre-empted quarters.

One of our graduates, Mr. F. E. Delano, a farmer of Oxford, Mich., writes me that last Friday, while engaged in tearing down a portion of his house preparatory to rebuilding, he noticed, about 3 p. m., bees flying in and out of some holes under the chamber floor. He supposed a swarm had taken possession, but was puzzled to know when they could have come without being heard or seen. The next morning early no bees were to be seen. About 9 a. m. a large swarm came and at once entered the same openings where the bees made ingress and egress the previous afternoon. This seems clearly to prove that scouts do, sometimes at least, go out to seek and prepare the new home before the bees swarm, and strengthens the probability that clustering is not to give time for this prospecting, but the rather to fit the queen for the long journey, which from her function and habits we must consider her ill-fitted to take.

The Rev. L. L. Langstroth has been invited to attend the Northwestern Bee-Keepers' Convention to be held at Chicago, Oct. 17 and 18, and accepts in the following language:

"About the invitation to attend the Convention at Chicago, and your very kind invitation to me to share your hospitalities, friend Newman, allow me to say, I accept both with great pleasure, and if nothing unforeseen should prevent, I will be glad to make the personal acquaintance of the Northwestern bee-keepers.

L. L. LANGSTROTH."

Fall Feeding for Bees.

A correspondent of the *Home Journal* details his method as follows:

Each colony should be examined, and, if out of stores, they should be fed about a pint of sweetened water every other day. This should be given them in the upper story of the hive, where other bees cannot get at it, or there will be danger of exciting robbery. This light feeding should be kept up to the latter part of September, and then the colony should be provided with their winter stores. I have found that about 15 pounds of a good article of "A" sugar is sufficient to carry an ordinary colony through till the warm days of spring.

There are many ways to feed sugar to bees, but I have adopted the following plan: Some kind of a feeder is necessary (and there are many kinds in use), and it should be cheap and simple. For handy and rapid feeding there is nothing better than a quart fruit jar and a grooved board. Cut a board 6 or 8 inches square, and with a pair of compasses strike a circle in its center about 4 inches in diameter, and cut a trench a quarter of an inch deep, similar to an old-fashioned cider platform press, and then cut grooves out to the circular trench, and the feeder is ready. The whole thing can be completed with a pocket-knife in a few minutes. To prepare the sugar for feeding, fill the jar full of sugar, then pour on warm water till the jar is full of syrup; have the sugar well dissolved by stirring it. Now put a piece of oil-cloth, or a piece of drilling will answer, on the mouth of the jar, and invert the jar and board altogether, and then slide the cloth out from under the mouth of the jar, and you have the feed in the best possible shape to be taken by the bees. I usually feed at the entrance of the hive, placing the feeders in position just after dark in the evening, and removing them early the next morning. At the start a little syrup should be strewn from the bees to the feeder, to start them, after which they will rush into the feeder like pigs into a swill pail. Keep up the feeding regularly till they are provided with sufficient winter stores. If the nights are cool, place the feeder in the upper stories of the hives. Some people seem to think that it is a risky thing to feed \$2 worth of sugar to a colony of bees. But if they give 100 per cent. profit, how then?

The Central Michigan Bee-Keepers' Association holds its fall meeting at Lansing, in the State Capitol building, on Tuesday, Sept. 25, 1883, at 9 a. m. All interested in anything pertaining to bee-culture are invited to attend and bring anything that will be of interest to the bee fraternity. E. N. Wood, Sec. North Lansing, Mich.

For the American Bee Journal.

Wintering—The Humidity Question.

JAMES HEDDON.

After reading Dr. Tinker's "Humidity" article on page 440, current volume, I am somewhat at a loss to know why he so carelessly passed by the fact that so many instances are recorded where bees come out of special repositories perfectly drenched with dampness, and the combs covered with blue mold, but with the bees perfectly healthy, and no signs of dysentery! Then, again, cases like my own, where 48 colonies put into a very dry cellar began to die in less than three weeks with dysentery in its worst form with the hives and combs all dry and entirely free from mold.

Bees about here have wintered best in the dampest winters, for these winters were the warmest ones, and the cold and confinement which are the great aggravations to the cause, were not with us in any great degree. No, the "Humidity" theory is a complete misfit for very many known instances. Mr. Arad Balch, of Kalamazoo, claimed that all upward ventilation was death, that dampness was good for bees, and all the while he made these claims, he wintered his bees with the greatest success, with everything moldy and damp; while we "dry" fellows lost ours by scores of colonies.

The Doctor's reasoning regarding the natural food and instinct of the bees does not hold good. Sugar syrup is not their natural food, but honey is; but the unnatural food is here the best. I have to thank the Doctor for his kind words regarding the object of my researches and reports concerning the cause and prevention of this trouble, and for calling the attention of bee-keepers to the fact that I am to have the "honors" of fathering the "pollen theory."

I wish to call attention to one more fact, which is, that the bacteria theory is much the same thing. My first proposition was that the cause of dysentery was "an over amount of animal or vegetable matter in the food." (I use the words "vegetable matter" not in the same sense that honey is vegetable.) I did not know whether bacteria was vegetable or animal, but rather thought it was the latter, while later developments prove that it is vegetable. Be that as it may, the two theories are very closely related, and Prof. Cook, who should be one of our very closest guessers upon this subject, yet fails to see so much fallacy in the pollen theory as our friend who sets his sections down flat on the brood frames.

To my own ear the Doctor's article savors of that knowledge of chemistry that his profession usually understands, but in his application of the

same to the cause of dysentery is where I disagree with him.

The Doctor thinks pollen, because a "normal food," would not produce dysentery. What is normal is natural. Nature, with her infinite arms, embraces all that there is. Death is as natural as life. Instinct is erring in all animated nature. No animal has instinct sufficiently unerring to make it always a success. The bee has an instinct to guard against the moth that nature so kindly furnished for its benefit; still moths do destroy feeble colonies often, and sometimes strong ones. With all the Doctor's instinct and reason combined, together with his experience and memory, I dare say disease will get him before old age.

It seems quite peculiar that the Doctor's instance of experiment with the pollen theory should be kind enough to kill that and the hybrid theory all at one fire. This is what sportsmen call a "double-shot." Well, if it turns out that Dr. Mason's three years' experiments, which have convinced him that pollen eating in confinement is the cause of dysentery, and that the hundreds of producers who have had their hybrids lead all other colonies for surplus honey should be true, then we shall be forced to think that in some way Dr. Tinker is as badly mistaken regarding his pollen experiment as he is regarding setting sections flat down on the brood frames, and that his hybrids were either catch hybrids, or that his parent colonies were not of the right sort to produce the hybrid so much sought after about these days. After all, have we not theorized enough, and is it not now a question of practical experiment?

During the coming winter we shall make the pollen theory a special matter of experiment, and give it the best test upon the largest scale we have ever heard of. The moment we find we are wrong, if such be the case, we shall get right off from that hobby horse and caution all to keep away from it as they would from the heels of a mule; and, Doctor, if we find you on our bacteria horse, we shall claim him, if he seems to have any strength, by right of priority, we shall order you to dismount at once and stride your "sections on the brood frame" pelter, one that we feel sure will never "get there."

Dowagiac, Mich.

Gleanings.

Standard Langstroth Hive & Frame.

L. L. LANGSTROTH.

Before inventing my movable frames I used bars, in a hive with movable top and bottom, by which the bars could be worked to much better advantage than by side-opening doors. My latest style of bar hives were 18 $\frac{1}{8}$ by 18 $\frac{1}{8}$ by 6 inches deep, all in the clear. At that time (1851) honey, to bring the best price, had to be in combs built in neat glassed boxes, and this shape of the hive gave an unusually large surface for such supers. The walls of these

hives were double glass, to give the dead air space, which protected the bees against extremes of heat or cold, and sudden changes of temperature. That fractional $\frac{1}{8}$, which has puzzled so many, gave room for two strips of wood, each one inch wide by 1-16th thick, against which the double glass could be fastened with glazier's points. One pane of glass, 18 by 12, a common commercial size, could be easily cut so as to answer for one side. My movable frame hives were first made in the spring of 1852, in the city of Philadelphia—some six months before the patent, which was applied for in January, was issued. These hives were 14 $\frac{1}{8}$ inches from front to rear, and 18 $\frac{1}{8}$ from side to side. Early in 1853 my hives were made in Greenfield, Mass., and the first edition of my book on the "Hive and Honey Bee" was published in May of that year. The present size of hives, 18 $\frac{1}{8}$ from front to rear, 14 $\frac{1}{8}$ from side to side, and 10 inches deep, was then adopted. The dimensions, 18 $\frac{1}{8}$ from front rear, and 10 inches deep, have never been changed; but that from side to side may vary according to the number of frames, some preferring 8, some 10, and some even more. I am correctly quoted as having said, in the AMERICAN BEE JOURNAL, in reply to an inquiry, "Considering the accuracy which may be obtained in making the frames stiff and perfectly square, I prefer the Root and Newman measurements." What I meant was, that frames could be made so stiff and square as to allow of their being $\frac{1}{4}$ of an inch longer than the old standard size, and that the $\frac{1}{4}$ inch (instead of $\frac{3}{8}$) still left between the uprights of the frames and the front and rear walls of the hive, gave all the room needed for their proper manipulation. It never occurred to me that any one could possibly suppose that I meant my frames could be improved in squareness or stiffness by making them only $\frac{1}{4}$ of an inch longer! I then thought that it was quite a desirable point to gain this $\frac{1}{4}$ inch, as in ten frames it gave an increase of comb surface enough for rearing over 1,100 bees.

As such large operators as Heddon, Root and Baldrige, insist that $\frac{3}{8}$ of an inch space between uprights of frames and hive is the least that can be safely allowed; and as hives are not unfrequently made, even by good workmen, which vary a little from the true dimensions, and further, as some kinds of lumber are badly affected by variations in the weather, I am now of opinion that $\frac{3}{8}$ is better than $\frac{1}{4}$.

Considering the frequency and severity of my attacks of head troubles, which not only prevent me from taking any interest in bee matters, but which render any thought upon such subjects both painful and dangerous, it will not seem surprising that it is only within a few weeks that I have learned that the change in the size of the standard Langstroth frame was made to carry with it a change in the size of the standard Langstroth hive! I have no recollection of ever having read the article to which Mr. Baldrige thinks I ought to have re-

sponded, until I saw his reference to it in the BEE JOURNAL of Aug. 8, or I should before this not only have corrected his misunderstanding of the reason I gave for preferring that extra $\frac{1}{4}$ inch, but should have expressed my deep regret that the size of the standard Langstroth hive had been changed; not that slight changes in frame and hive are of any special importance, except as they interfere to any extent with the cardinal principle, that any Langstroth frame ought to fit in every Langstroth hive. Even after I ceased to use the double glass walls, the fractional $\frac{1}{8}$ was retained to prevent confusion by departing even to so small an extent from the size so widely disseminated.

It is, however, very easy to exaggerate the inconveniences which have resulted from these slight variations. One will contend that the standard Langstroth frame cannot be used in the Root and Newman Langstroth hive, and many will actually prefer that size of hive for them, as giving more room for the safe and rapid handling of frames. If both hives and frames are *very carefully* made, I find no trouble in using the Root and Newman frame in the standard Langstroth hive. The great length of the top-bar of the Langstroth frame enables me, after removing one frame from the hive, to take out the others with great ease, thus:

When the frame (1) is lifted out, the end (C) of frame (2) is *drawn* toward the operator, without any lifting until the angle is large enough to remove it without danger of hitting the sides of the hive; so in replacing it the end (2) is first put on the rabbet, and (C) can then be moved readily to its place. The long leverage of the Langstroth frames greatly favors such manipulations. I would say here, that a variation of only $\frac{1}{8}$ from front to rear, if it is on the side of making the hive *smaller* (say only 18 inches), is, for divers reasons, a much more serious matter than the extra $\frac{1}{4}$ inch; for in such hives it is well-nigh impossible to have any free manipulation of the longer frames. I am using in my own apiary the Root size of frame in the standard Langstroth hive, and find no trouble at all in doing so. I would even prefer, with hives and frames made as accurately as they should be, $\frac{1}{4}$ inch space, manipulating in the manner above described, to $\frac{1}{8}$ inch, if the frames had to be squarely lifted out.

The conclusion of the whole matter seems to me to be this: The standard Langstroth hive is 18 $\frac{1}{8}$ inches from front to rear, and 10 inches deep, all in the clear, and the standard Langstroth frame is 17 $\frac{3}{8}$, and not 17 $\frac{5}{8}$; and I advise all who make new hives, if they can do so without too much loss, not to vary at all from these measurements. I certainly have no right to demand that the parties who are using the extra $\frac{1}{4}$ inch, both for hive and frame, should

return to the old standard; but I hope that, instead of calling their hives the standard Langstroth hives, they will call them the Root Langstroth hives, as Mr. Root first used the extra $\frac{1}{4}$ inch. I presume that Messrs. Root and Newman, and other hive makers, if not willing to return to the standard Langstroth, will have no objections to filling orders for Simplicity, chaff, or other styles of hives of the Langstroth standard size.

Intending in another article to give in detail my reasons for adopting my standard size of frame, I will close by saying that I no more claim perfection for it now than I did in 1853, when in the full gush of enthusiasm over an invention which I hoped would revolutionize practical bee-keeping.

Oxford, Ohio, August, 1883.

[As we promised that the discussion of the hive question should stop with the articles of Mr. Langstroth, we refrain from making any comments. We are satisfied that a universal standard frame is an impossibility in America, and, therefore, it is useless to discuss the matter any further. Let all adopt such as they prefer—ED.]

For the American Bee Journal.

A Help in Handling Brood Frames.

G. A. DEADMAN.

Those who have either used, or read of Jones' brood frames, are probably aware that on account of their peculiar construction they can be handled very rapidly, with little danger of killing bees. This peculiar construction is principally in the bottom bar, which is simply a narrow strip of wood about $\frac{1}{8}$ by $\frac{1}{2}$ inch, and being placed edgewise, is made to pass through a groove made at the bottom of each of the side pieces of the frame, and projecting behind them about $\frac{1}{4}$ of an inch, or just sufficient to allow it to be placed easily in the hive. The corners are then brought to a point. It certainly has its advantages, as it is only by carelessness on the part of the operator that any bee is injured when manipulating them. Another advantage is, that it always hangs square in the hive, and, therefore, equi-distant from either side. There is one objection that I find in its use, although I have never inquired of the originator to know whether he has experienced the same trouble. The difficulty with me is this: The frame, when in position, brings the bottom bar about $\frac{1}{2}$ inch from the bottom of the hive, and as the bar itself is about $\frac{1}{2}$ inch, the bees are compelled to cease building comb one inch from the bottom board, or else build past this narrow strip. This latter alternative they very frequently adopt, and are sure to do so if the frame does not hang straight with the full sheet of foundation.

I presume some will say that there is no reason why it should not hang perfectly straight, but with a deep frame, $\frac{1}{8}$ inch is very little from the

true, and yet sufficient to encourage the bees to build cells at least on one side of the comb, or rather comb with cells on one side. And worst of all, when using full sheets of foundation of worker cells, the bees will take advantage of the situation and complete it with drone comb, the very worst place they could do so, as far as handling the frames are concerned. Now, the plan I adopt, and possibly there are several others doing the same, is this: I have the bottom bar the same width as the side pieces of the frame, as is customary with the majority of frames made, and then I procure from the hardware store $\frac{5}{8}$ inch brass window blind staples, costing 15 cents for half a pound, and sufficient for at least 500 frames. I drive one of these in each side of the frame opposite the bottom bar, and allow them to project $\frac{1}{4}$ of an inch, or not more than $\frac{1}{16}$. By using these I cannot see but that all the advantages of that part of the Jones frame can be had without any of the objections as mentioned above, and as you will see the cost is comparatively nothing.

Country Gentleman.

Fall Notes About Bee-Keeping.

W. Z. HUTCHINSON.

The hurrying season is over, but there yet remains much work to be done. Comb honey should be stored in a dry, well-ventilated, and rather warm room, in order that it may become thoroughly ripened, and the honey in any unsealed cells become so thickened by evaporation that it will remain in the cells even though they should be turned upside down. Neat, smooth shipping crates should be made of some light-colored wood, and at least one side of the crate should have a slip of glass to show the honey. Although the crates should be neatly made, yet they should be so cheap that they can be given away with the honey. All propolis, or gum, should be carefully scraped from the sections. All honey should be graded, and that containing even a little dark honey should be placed in the second grade, otherwise the whole lot is liable to be classed as second grade. If extracted honey is to be sold in small pails, now is the time to put it into them, as after it has candied it is a slow, disagreeable task to put it into pails.

Many bee-keepers err in putting their honey upon the market too early in the season, and at too low a price. After reading a few encouraging reports in the bee papers, they fear that there will be a glut in the honey market, and in their efforts to secure the highest price by rushing their honey into the market before there is a demand for it, they often get the lowest price, and help to spoil the market for others. Until the fruit season closes the demand for honey is light, and bee-keepers should govern themselves accordingly. The honey should be well graded, put up in the most attractive packages possible.

well taken care of, and placed upon the market when there is a demand at a remunerative price, and not before. There is one other point; before honey is shipped away to a large city, the home market should be well supplied. Supply the home market first, and if there is any left over, there will be time to sell it at some distant market. One who has never tried it will be surprised at the quantity of honey that can be sold in a home market, especially when an energetic man goes at it in the right manner. Each grocer should be furnished with a neat stand for extracted honey; also a case, with glass front, for comb honey; and unless sold outright to the grocer, he should be instructed to sell the honey at a certain price.

As I rear queens, I do not have a great deal of honey. I have at present taken off about 3,000 pounds, but have not sold more than 100 pounds. I have been too busy to even get it crated, or to put the extracted into pails, but there is time enough yet for that, as October is the best month in which to sell honey. Before selling my honey, I shall probably exhibit it, together with numerous other bee-keeping articles, at the State Fair at Detroit.

For some reason, some colonies at this season of the year are found queenless. Perhaps the large number of eggs laid during the busy season is so great a tax upon the vitality of old queens that they die, and then the young queen that the bees afterwards rear is lost in mating. Of all the methods that I have tried for introducing queens that have been long out of the hive, I have found none better than the following:

Make a cage of wire cloth by rolling a piece 3 or 4 inches square around a round stick $\frac{3}{4}$ of an inch in diameter. One edge of the cloth should be unraveled a few wires, and the long ends of the wires thus left sticking out can be thrust through the meshes of the opposite edge, then bent over or "clinched." The cage when finished is simply a wire cloth tube 4 inches long and $\frac{3}{4}$ of an inch in diameter. One end can be closed by pinching it together. The cage in which the queen has been shipped should be opened in a close room before a window, the queen alone caught and placed in the wire cloth cage, and the cage closed by squeezing the end together. Then by moving the frames slightly apart the cage can be slipped down between two of them and held in place by pressing the combs against it. For fear the bees might neglect to feed the queen it is better that the cage be placed against sealed honey. In from 24 to 48 hours it is usually safe to liberate the queen. The disposition of the bees towards the queen is the only guide as to when it is safe to release her. If they are "balling" the cage—clinging to it like burdocks—they would kill the queen; if they are walking about over the cage in their usual unconcerned manner, they will usually accept the queen, and the cage can be opened by pressing one end in the opposite direction from that by which it was closed. After

opening the cage the hive should be closed at once, and not opened or the bees disturbed again for 5 or 6 days. Opening the hives before the queen has entirely recovered from her captivity, and been completely accepted as sovereign of the hive often leads to her destruction.

Colonies that are to be united should be united now. Remove the least desirable queen, and in two days take the combs containing the brood of both colonies and put them together with the adhering bees, in one hive, and place it upon the stand occupied by the colony having the queen.

At this season of the year robber bees are often troublesome; hence caution should be used, and no temptations, in the shape of exposed sweets or queenless or weak colonies, should be placed in their way. When robbing is once started, it is difficult of control. Once more I would urge upon beekeepers the importance of experimenting in regard to wintering. Extract the honey from a few colonies, and feed them a syrup made from granulated sugar, in the proportion of one quart of hot water to 4 pounds of sugar. The syrup should be fed during the latter part of September.

Rogersville, Mich.

For the American Bee Journal.

Appearances Are Often Deceptive.

W. H. STEWART.

A truth, often apparent to the observing bee-keeper, is, "we know not what a day may bring forth." If we could have known that the cold, wet spring of 1882 was a true index to the latter part of the season, we would have concluded that it were better to let the bees go, and get out of the business, as best we could; but we have all learned that there are "ups" as well as "downs" in life. Thus it is, that, during the storm "hope sees a star," as I have stated in my report for 1882. The season of 1882, after June 10, was very good, and we made the bees pay tolerably well.

The spring of 1883 (in Wisconsin) was more promising; we had to feed but little. Bees obtained plenty of pollen and nearly as much honey as they needed, up to June 8, and then came white clover bloom, and we took about 2,500 lbs. of white clover surplus. In the spring of 1882 we did not get 50 lbs. of surplus white clover honey.

July 13 (this season) basswood began to open its bloom, with which it was literally loaded. Reports were made from many parts of the country, giving great honey yields, and, as the organ of hope is ever flattering us, by presenting the brightest and most pleasing side of every question, how natural it was for us all to conclude that the land was sown to "flow with milk and honey" (or at least with honey).

But how about the "immense crop?" When basswood began to bloom, dark clouds, somewhat larger than a man's hand, made their appearance, and thunder and lightning, rain and wind were the order of both day and night

during basswood bloom. Our bees only had half a day of favorable weather for gathering basswood honey.

On July 12, we had run all our surplus combs through the extractor, and had our sleeves rolled up, ready to take about 6,000 lbs. of basswood honey in, "out of the wet;" but we failed, and the wet came out ahead.

July 20, we opened our hives to look for a little basswood honey; we did not expect much, but we found scarce anything in the supers, except mad, ugly bees.

Now, two weeks later, nothing seems to be going on with the bees, except trying to force their way into every door and window, to get at the honey that is being handled, and doing their best to rob each other of stores.

Again the great thunder storm has brought chilling winds and stormy indications of frost. If this state of things continues, we will have to feed most of our white clover honey back, for winter stores.

Orion, Wis., Aug. 4, 1883.

For the American Bee Journal.

A New Bee Enemy.

PROF. A. J. COOK.

The figure we here present is of a curious bee-killer received from J. D. Enas, Napa, Cal. Mr. Enas says it goes into the hives and destroys the bees.

This strange animal is related to the spiders, and more nearly to that group of the spiders containing the

Bee-Killer.

scorpion and grand-father-gray-beard. The name of the family is Solpugidæ, and they are unique in the possession of very curious jaws. These have two toothed fingers, the lower one of which is movable. On the front margin of the head, which seems small when compared with the enormous jaws, are the small rounded eyes. The jaws move side-wise, while the toothed fingers move up and down. There are eight legs as with all spiders, though the anterior ones have no claws.

The species sent by Mr. Enas is possibly *Datames Californicus*, Simon, though this one does not quite agree with the description given by the late Mr. Putnam in his most admirable monograph of the Solpugidæ of America. It is nearly one inch (23 m m) long. The head is brown, with

a light stripe in the centre. The remainder of the dorsal surface is lead color. The eyes are black, while the jaws and legs are light. The fingers and their teeth are brown, tipped with black. The femurs and tibia are brownish. At the base of each posterior leg are fine small scales. The specimen I have is a female. The reproductive slit is on the under side of the first abdominal segment; the anal one on the last.

Mr. Enas has seen several of these animals killing his bees, and I hope soon to have from him more specimens.

It is a very interesting group of animals, and it is a sad loss to science that Mr. Putnam did not live to complete the admirable work in the study of these animals, which his scholarly and thoroughly scientific habits fitted him so well to perform.

The figure shows the jaws with their toothed fingers, a posterior leg, and the animal with the jaws turned a little to one side, so as to show the teeth of the fingers.

Lansing, Mich., Sept. 11, 1883.

For the American Bee Journal.

Robbing, Fertile Workers, etc.

JOHN GOCHENOUR.

I would say for the benefit of Mr. B. L. Clements, on page 433, that I have successfully prevented my bees from robbing by inverting, or rather turning the entrance blocks end for end, so as to form an entrance 3 inches long and an inch wide, or less, according to the desperation of the robbers. By placing a small block on top, it makes a gauntlet that no robber can safely run, as they will be caught by the sentinels before they get half way into the hive. Mr. Clements gives Italians more credit for honesty than I can; when they find a hive unable to protect itself, they are like rats, and quarrel among themselves. I would be pleased to have some one explain why fertile workers get possession of the hive, and the best way to get rid of them. Are they considered hybrids because their product are all drones? I have heard it argued by a man that claims that he has been in the bee business for 12 years, that the fertile worker is a female drone; which seems very unreasonable. I would be under obligations to any who will answer the above questions fully; I would like to hear from more than one, as, perhaps, there are different views and theories upon the question.

Freeport, Ill., Sept. 5, 1883.

For the American Bee Journal.

Iowa State Fair Exhibit.

EUGENE SECOR.

At the Iowa State Fair, just closed, the finest display of honey and implements pertaining to the apiary was made which we have seen at any exhibition in the State.

The bee and honey department—assigned to one wing of Vegetable Hall—was under the supervision of Rev. O. Clute, of Iowa City, author of "Blessed Bees." It was a pleasure to witness his enthusiasm, and the willingness and courtesy with which he answered all queries, whether pertinent or not. The eager crowd kept up such a running fire of questions that he was obliged to talk all the time, or dodge the crowd and retire to his tent for a few moments rest. I was on the ground three different days, and I saw no cessation in the interest taken in this department.

Mr. Clute made a very attractive display of extracted honey—of which he makes a specialty—and of bee literature and apianary implements, hives and bees. J. J. Kiser, of Des Moines, also made a good exhibit, including comb honey. A Fairfield apiary—we do not now recall the owner's name—took first premium for the largest and finest display of comb honey in section boxes.

A meeting was held at Mr. Clute's tent one evening during the Fair, and a State Association was formed. Mr. Clute was elected President. We may, therefore, expect to see even a finer exhibition another year.

Forest City, Iowa, Sept. 8, 1883.

SELECTIONS FROM OUR LETTER BOX

Crop Report.

The honey season for this part of the State is past. Bees have gathered nothing since the basswood honey harvest. The weather is very cold both night and day, and the stores for winter are becoming less. Bees did well for such a cold and wet season. I had 24 colonies, spring count; increased to 55, and extracted 4,300 pounds of honey from basswood; some colonies gathering 25 or 30 pounds a day.

B. D. SCOTT.

Ovid Centre, N. Y., Sept. 9, 1883.

Heavy Frost.

Last night there was a heavy frost, which, I presume, put an end to the fall flowers in this part of the country. My bees have been on duty about half of the time in the last two weeks. There are several good buckwheat patches near my apiary, but last night put an end to progress in that line of business. As soon as my bees began to fly this morning, the Italians commenced war on some of my hybrids. The fight lasted about one hour, and the Italians drew off in good order. There were several hundred killed and wounded. I did not take time to count them, as they were very saucy. They gave me to understand that I was not needed in the fight. A few of my late swarms I shall have to feed. When is the best time and the best way? Please answer in the BEE JOURNAL—some one that is experienced in the busi-

ness. I get the BEE JOURNAL regularly, and could hardly do without it, as it is just what every beginner wants. I was up to Columbus, last week, and found a nice display of honey and bees. Found Henry Drum, of Adelphi, on hand with all the improvements of apiculture.

R. A. ROSSER.

Nelsonville, Ohio, Sept. 9, 1883.

The Season's Work.

I have just got through taking off the surplus. My apiary consists of 32 colonies; 20 young and 12 last year's queens. I wintered 23 colonies in the cellar; they all came out alive; I lost 4 queens in the latter part of April. I have had 2,700 pounds of extracted honey; it is nearly all sold at 8 cents per pound, cash; and about 112 pounds of comb in two-pound sections; this brings 14 cents per pound in trade. This beat me out of 300 pounds, if not more, of extracted honey. I shall not try for any more. My greatest trouble is in introducing young queens, this fall. I had to make new colonies for this. I only find fault with the Cyprians; they will not accept a queen, if there is an old bee in the hive, and in 24 hours you will find drone eggs in several combs. This is a hot game for a novice to get over. I have them all right now, and do not fear the winter, whether it be cold or not. I will not have over 50 colonies to attend to next spring; I had 200 this spring, but this was too much for me to attend to.

JOHN H. GUENTHER.

Theresa, Wis., Sept. 7, 1883.

Bees in Marshall County, Iowa.

Our grand prospect for a large honey yield suddenly came to a close early in August; since then our bees have only gathered enough to keep up a good stock of brood; so now our colonies are generally strong and in good condition for a September harvest, if we have one, and so far they are making a good start, if lively work is any sign. I think a shower followed by a few warm days and we would be all right for winter stores. If we do not get it we will have some feeding to do. Some of the best honey harvests I have ever seen have been in the first half of September, therefore, I still live in hopes and shall until frost comes. I met with a number of bee-keepers at our County Fair, and all said they got none, or but little surplus during August. All thought it was almost too cold. It seems that good corn weather makes good bee weather. There was a small show of honey at the Fair. S. W. Keeler took the first premium on comb honey, and the writer got it on extracted honey. The president of the Fair promised us a special department for a bee and honey show next year, if the bee-keepers of the county would meet with the Agricultural Society at the annual meeting in January, and help make out a programme. I hope all bee-keepers of Marshall County, Iowa, who are interested, will respond.

J. W. SANDERS.

Le Grand, Iowa, Sept. 6, 1883.

Gaura as a Honey Producer.

I enclose a sprig of a flower that grows wild along the roadside. I wish you would give, in the BEE JOURNAL, a scientific description of it, and what honey qualities it possesses.

JOHN GOCHENOUR.

Freeport, Ill., Sept. 1, 1883.

[This is a rather common plant, known to the botanist as *Gaura biennis*. The only common name is that of the genus, or first word in italics. It is biennial. The first year the long leaves spread out from a center after the fashion of a turnip; the second year a branched stem 4 feet high appears, bearing small flowers and close rows of seed vessels. The pollen is stuck together loosely by cob-webby hairs or threads. Bees are sometimes bothered to free themselves from these masses, though there is not nearly the dough that there is in the milk-weeds in this respect. The plant produces some honey.—T. J. B.]

An Amateur's Tribulations.

In July I sent to Mr. James Heddon for an Italian queen, which I received Aug. 2. I placed her in an improved Langstroth hive with 4 frames of empty comb, and 6 frames of foundation. I then reversed a box hive and drove the bees (not very successfully I fear) into the hive with the new queen, and placed it on the stand from which I had taken the box hive. I placed the old hive to one side, and awaited events. The next day I found but few bees in the Langstroth hive, and a few or none in the old hive, but a box hive next to the Langstroth was and is overflowing with bees. I then removed the new hive to another part of the yard, bored some holes in the bee board, and put a hive with a late swarm on the top and stopped the entrance, thus forcing the bees to pass down and through the Langstroth hive, and commenced feeding. The next day my wife took the old box hive to the lower end of the yard, turned it on its side, and broke out some of the combs which were very black and old. I concluded to extract the wax from the comb in this hive, as it appeared to be strong and heavy, and went to work breaking out the combs, a piece at a time, finding a few bees among the combs. As I got nearer the top, I found more and more bees, when, as I got to one of the upper corners, I found a score or more of bees, and away flew my Italian queen; she sailed off majestically, but got tangled in some spider web on a neighboring fence. I then procured a glass tumbler, but on returning my queen had freed herself and disappeared; she came back, however, in a few minutes, to the hive, and I secured her; fortunately I had Mr. Heddon's queen cage, and put her in, and set the cage in the portico of the before-mentioned Langstroth hive. The cage was soon

covered with bees; in the evening, just at dark, I opened the cage and drove her into the hive; this final act of the drama, occurred some ten days ago. Last Sunday, on returning from a professional call, at or near noon, my attention was called to the humming of bees in a maple tree in the yard, near the bee hives. I looked up and found a cluster of a pint or a little more about 18 feet from the ground. After trying with pail and basket in vain, I broke off the branch; they clustered close by on another limb. I broke that off, and they circled around for a short time, then followed the bush, which was laying close by the hive, and clustered on it. I shook them off, and they settled on the top of the hive. I tried to drive them in with a Bingham smoker, when they again took wing; this time they went about 60 yards, and settled in the top of a box elder. I got a ladder, went up, sawed off the top and threw it down, but they held fast. I then cut off the twig with the cluster, laid it on the frames, put on the bee board, and there they are. Two things interested me: They never offered to sting, and they are Italians. I never worked with bees so good-natured, not an angry hum from one of them. Where did they come from? There are no Italians in our neighborhood. The Heddon queen is the first. Can they be from her? This does not seem possible, nor do I think there are Italians near enough to have furnished this swarm.

THOS. MARTIN.

Coal Valley, Ill., August, 1883.

[To be sure of answering your tribulations correctly, one would need to be at the scene of action. I will venture to suggest, however, that your first mistake was in not blanketing the box hive to be forced, a few days before driving it, when the blanket could be changed to your Langstroth hive, making that and the driven box look alike, which in your case they did not, which made them go to the other box near by, that looked like their former home.

In introducing a valuable queen, do not accompany the job with other uncertain manipulations. Are we to understand that the late swarm you put on the Langstroth hive containing our queen, had a queen of their own? Whether they did or not, the proceeding was all wrong and risky to the newly-introduced queen. A little farther on, it seems your new queen is in the old box hive; this I do not understand. How you came by the Italian bees is another mystery. Undoubtedly a small swarm came to you that you found in the tree. Swarms sometimes travel scores of miles. No, it is not possible that those bees came from the queen I sent you.—JAMES HEDDON.]

Honey Crop in Nebraska.

The honey production of this season has been very light, our best colonies not gathering to exceed 50 to 75 lbs. of surplus. Prices are somewhat above the average. Comb honey is selling for 25 cts. per lb., and extracted for 16 cts.

F. E. BENEDICT.

Reynolds, Neb., Sept 11, 1883.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Bees in a Garret.

My uncle has a house with a verandah some 7 feet wide, attached to a two-story house lathed and plastered underside, thus forming the ceiling. The rafters, which project up at a suitable angle against the house, form a roof covered with tin. Of course a little garret is formed between the rafters and the ceiling. A swarm of bees has been discovered which found an entrance by a crack in the cornice, a piece of the moulding having become loosened. The presumption is, that the bees have the whole space of the garret which they can occupy as they choose. The question now is, by what means, if any, these intelligent little insects can be persuaded to abandon their present domicile and enter a hive, so that their labor may be utilized. At present we can see no way of collecting rent from the occupants of the dwelling. Please be kind enough to answer in the Weekly BEE JOURNAL.

HELEN L. JOHNSON.

Middle Haddam, Ct., Sept. 7, 1883.

ANSWER.—As it would require a skillful operator to take the bees, combs, etc., from the garret, and cost in repairing the same and all, more than to buy a colony, why not just let them remain where they are? They may swarm, and then hive them and keep the garret colony for a stock hive. This is how I should manage them, and the novelty and opportunity for "the folks" to exercise their marvelousness regarding the immense stores that "may be in the garret," is worth something, is it not? If they must come out, tear open the verandah and smoke the bees, cutting out their combs one by one, brush the bees into a hive, transfer any of the combs to the frames of the hive that are large and straight enough, stop up the verandah and place the hive on the ground just below, to be moved after the bees are all quiet. All the minutia of the work depends upon the condition of the place where it is to be done, and cannot be directed here.

Bees Cleaning Combs.

What is the best method of having bees clean the comb, after the honey has been extracted?

H. A. WHITTLESEY.

Newington, Vt., Aug. 27, 1883.

ANSWER.—If you have a good extractor, no such cleaning is necessary. But the best way I know of, is to put the combs into a super, or upper story, and place this over a strong colony just at night if in times of a honey dearth, and in 4 to 12 hours the combs will be all clean, and the super can be removed in the usual way.

Beautiful Honey.

Our Boston, neighboring city and home markets, are yearly filled with the most beautiful honey. The combs are snowy white, in perfectly clean, white poplar sections, filled to the corners and completely sealed. With the above I am obliged to compete in producing comb honey. My sources of honey are mainly willow, fruit-bloom, locust, raspberries, bass-wood and goldenrod. My bees are Italians. Quantity and quality of extracted honey, per colony, is above the average. Not so with comb honey except, perhaps, in point of flavor. Now, then, if it is management that forms the most important part in producing such beautiful white comb honey, what are the details or the fundamental law governing the same?

If fixtures, what influence do they exert on both quantity and appearance?

If location, how can I best utilize, or if needed, improve the one occupied?

If bees, must I discard my clean, sprightly, courageous Italians, and notwithstanding the protest within, endure the moth, lazy blacks?

If Mr. Heddon will please answer the above questions through the "What and How" columns of the BEE JOURNAL, he will greatly oblige
L. H. SHEVENELL.

Haverhill, Mass., Sept. 7, 1883.

ANSWER.—My advice to you is, just make the raising of extracted honey a specialty, and adhere to the bees that you prefer. I know of locations where to raise choice white comb honey is very much more difficult than in other places only 10 miles distant, with everything else except the resource for nectar the same. It is plain to be seen that time and the Yankee will make the production of comb and extracted honey equally profitable, and a choice as to which we will produce should depend upon the fitness of our field and ourselves. If you are going to raise extracted honey for sauce, consult Dadant's little 15 cent book upon the subject. If for mechanical purposes, then a different management is advisable.

Believing as I do that your flora is the main obstacle, I will not answer your questions until I may know that you are bound to go for comb honey, which I may find out by your next communication.

Preparing Bees for Winter.

Will Mr. Heddon please answer the following queries in the BEE JOURNAL in regard to box hives, as there are several around here who have a few colonies of bees in box hives:

1. In case there was not honey enough in the hive for winter, what would be the best food, and the best way to feed them?

2. How would you advise preparing them for winter, and what is the best material to pack them with?

3. Would it be a good plan to make a box a few inches larger, each way, than the hive, and set the hive in it, and pack chaff around it?

J. S. BARB.

Bristolville, Ohio, Sept. 3, 1883.

ANSWER.—1. If I had such bees in box hives, I should be tempted to take them up, considering the honey they now have, and combs for wax, rather than to feed them more dollar's worth, and then risk their coming through in a condition to make them worth what they will cost you.

2. Properly prepared, pure cane sugar syrup (if it can be got pure, which my investigations throw a great shadow of doubt upon) or honey is good food, and if the box hives have no openings above, they might be inverted and a feeder placed on the open top (previously bottom) and all removed in the morning, before the bees fly, and fixed at night after they cease flying. Feeding in a successful manner, and properly preparing the food, is one of the fine arts of bee-keeping, and if we are to learn it properly and with certainty, we need to see it demonstrated. There are so many twists and turns to be made—according to the condition of the apiary, the bees to be fed, and the weather. A good feeder is an absolute necessity.

1. Do bees gather pollen from white and Alsike clovers? I have seen them at different times working on those clovers, and at the same time they had pollen on their legs.

2. Are queens that leave the hive with second or "after swarms," mated with the drone before leaving the hive with the swarm?

3. How old are queens before they leave the hive to mate with the drone or with second or after swarms?

Bristolville, O. J. S. BARB.

ANSWER.—1. As near as my limited time has allowed me to discover, I think white and alsike clover yield

pollen in such quantities that our bees do sometimes gather from it, here, but usually it affords too much honey to tempt them to gather its pollen.

2. No, the queen mates with the drones usually, about 3 to 5 days after the swarm is hived, with all after-swarms.

3. After-swarms often issue a few hours after the hatching of the young queen, or queens, that accompany them.

Dzierzon Theory, etc.

I am a subscriber of the Weekly AMERICAN BEE JOURNAL, *Gleanings, Exchange, and Bee and Poultry Magazine*. I am also owner and reader of all the books written on the science of apiculture, both in America and Europe. Have had several years practice in bee-keeping in the West Indies, and was originally taught by father Dzierzon's "Rational Bee-Keeping" many years ago; but still I find there is something yet wanted which neither practice nor theory will ever solve, namely: the proof positive that an unimpregnated egg laid by a queen bee can, or does produce a drone. This, to me, seems unnatural, for this reason: an unimpregnated egg will and must always remain an unimpregnated egg, and could never produce a bee that is capable of impregnating, as from nothing nothing must remain; the greater part of this world thinks that "nothing" really exists, and will try with strong arguments to prove it; but the very fact of its being "nothing" would not make it something, therefore would be "no where," and then, pray, where is "no where;" just fancy for a moment anything in existence without length, breadth, width, depth or thickness, this would be "nothing," but this is not within the grasp of human imagination; therefore, as I have said, "nothing" does not really exist, consequently under this head an unimpregnated egg of a queen bee cannot, in my opinion, produce a drone bee. I am afraid that we do not as yet really understand the principle functions of her nature, although that has nothing particularly to do with the dollars and cents part of the bee business; although if we knew these particular functions more accurately, we might be able to breed up to a standard of perfection; however, as I like your style of explanations, and your reasonable answers given to all questions put, would you oblige me by answering a few through the Weekly BEE JOURNAL:

1. Are those queen-cells built over drone eggs in a queenless colony supposed to become the drones that impregnate the queen? I have had them in this apiary on the same sheet of brood that had real queen-cells built over worker eggs at one and the same time. They are easily known by their smooth surfaces, and the drone comb on which they are built.

2. Why do the bees provide such royal drones (which they must be as they are fed on royal jelly, and pro-

vided with very expensive cells) when they must know (through the use of their five senses) that other legitimate queen-cells are built at the same time? I have had them hatch in this apiary, and the colony has become very prosperous and strong. I have also seen some torn down as is done even to the *bona fide* cells. When they hatch before her majesty they get the chance of existence, but if she hatches first, some of them stand a poor chance, and are generally torn down, but not always.

3. If impregnation takes place up into the open air, who, when, where and how have they witnessed it? I think, all things considered, the impregnation question must be going on from the moment the queen has sufficient age for the purpose, or even directly after birth inside of the hive, and the queen takes a trip out for an airing before going properly to work in laying. I do not believe in fertile workers, but I do believe in a drone-laying queen, and I am afraid that they are such as are called fertile workers.

4. Is the queen impregnated "once for all," which lasts her life time, or does she renew the process each time of natural swarming, or is the business carried on constantly in the hive? I think the latter is much more reasonable to believe.

5. How can it be possible that so small a sack of the seminal fluid can prove sufficient for impregnating so many thousands and thousands of eggs laid by her during her life time, if even but of short duration? This, I think, must be constantly renewed in the hive by the drones, for the safe and prosperous keeping of the family or colony.

I must beg pardon for occupying your precious time in reading this; but I hope you will excuse me as I am a very great enthusiast in the science of apiculture, and have, therefore, applied to your better knowledge and practice on the subject. I am always on the look-out for your articles in the bee papers, and have thought often of asking you the question: Why do you not write a standard work on apiculture, embodying all of your own experience in practice up to the present time and style of working? Such a work would be worth its weight in gold. I for my part would willingly pay \$5 for a copy. Try and get up such a one, and let it be in Mr. Langstroth's style, but up to the times in every respect. I hear of Prof. Cook's new book, and have sent for one, but I think you have proven to the fraternity that you "have got there." I am very sorry to hear of your winter losses, but trust you will make it up again soon. Please encourage the bee reading public with something good every time.

I am a Dane, so please excuse my English writing and explanations; but as a practical man, I presume you will understand me.

I have now working 80 colonies of the common brown bee. They have been transferred from Palm-logs into the Van Deuzen-Nellis improved (by

me to suit this climate). Simplicity hives, and are doing pretty well, considering the bad season we have had this year. I am just through with this lot, and I am going to increase with 50 more colonies just brought in Palm-logs. I am doing all in my power to introduce apiculture scientifically here, and feel so happy to hear constantly of its progress in the United States and Europe.

LORENZO J. DE SOBOTKER.
Santo Domingo, West Indies.

ANSWER.—1. Prof. Cook is a much better personage to answer your questions than I am, and as you say, truly these things have less to do with our dollar and cent success, and I commenced very poor in the business, having to make dollars and cents out of it, or go hungry to bed. I have paid most of my attention to the practical part of apiculture. As I understand the Dzierzon theory, drones are always hatched from unimpregnated eggs, whether laid by an impregnated or unimpregnated queen, and that the drones hatched from eggs laid by an unimpregnated queen, whether in queen or drone cells, are in every way a perfect male bee, possessing all the functions of the same. If what we have supposed to be fertile workers were unimpregnated queens, they certainly resemble a worker bee, and may as well be called fertile workers as queens.

2. I think this is the first time I ever heard of "royal drones," and was of the opinion that when drones or workers hatched from queen-cells, it was only another of the mistakes which proves the failure of bee instinct.

3. I know of one reputable man who says he saw a queen surrounded by a whole bundle of drones fall to the earth. This man knew nothing of the modern impregnation theory. Never read a bee journal or book. Twice I have seen a queen return to a nucleus with what I took to be evident signs of recent impregnation.

4. If queens are impregnated on the wing only, then we know one impregnation lasts for life.

5. So wonderful are things in nature, when seen by the telescope or microscope, looking into the far-off in either direction, that I am not prepared to say that what might look to the naked eye as a small particle might not be divided up into thousands and thousands of particles, each efficient in its nature.

All the above has less interest to me than other themes connected with modern apiculture. Very many have

asked me the same question, why I do not write a standard work on apiculture, or publish a bee journal. Let me here make my reply. I do not consider myself capable of doing either, and doing it *well*. I might associate myself with some one and get out a respectable journal, but I have been far enough behind the scenes to fully realize that he who publishes a good journal, is giving his life to his patrons, something that I am too selfish to exchange for honors or money.

Regarding a book on apiculture, in my judgment no one man in the United States has or can write a book to meet the present demands of progressive bee-keepers. Once that could be and was done by Mr. Langstroth, but to-day the demands are beyond the power of any one person to supply. I consider Prof. Cook's book worth more than its price, for its treatise on botany and entomology, but in my judgment he should have stopped there, naming his book "The Entomology and Botany of Apiculture."

Our "winter losses" are among the forgotten, as we now have 300 colonies in good condition, and believe for the first time during our 16 years experience that we are about to master the wintering problem.

Thanking you for your eulogistic words, I will say that I am continually making new determinations to make my contributions more pleasant and profitable to the reader. Your good letter needs no excuses.

Leather-Colored Italians.

Will Mr. Heddon please answer the following questions in the BEE JOURNAL:

1. Are the leather-colored Italian queens of a distinct race, or is the dark color caused by a cross from other strains of bees?

2. Will a colony of bees accept a queen that has fertile workers?

3. Will a fertile worker lay eggs in worker comb?

4. How do you manage a colony that has a fertile worker, to get rid of them?

5. Which is the best, natural base foundation or flat bottom?

6. Where can I get the Parker foundation fastener?

HARVARD T. BUSH.

Monticello, N. Y., Aug. 31, 1883.

ANSWERS.—1. The leather-colored variety of the Italian race may be thus dark colored from crossing with the German race far in the past in their native home, Italy. I do not know how that may or may not be. I do not think any one knows. This

type of bee is brought from Italy, and all have three bands, and duplicate themselves generation after generation. If they are not the original Italian bee, they are certainly a fixed strain, and according to most of our leading honey-producers, the most desirable fixed strain or race of bees known.

2. Sometimes they will, but the uncertainty is too great to risk the life of a valuable queen by attempting such introduction.

3. Fertile workers lay eggs in worker combs, and when capped over the cappings project outwards.

4. In getting rid of fertile workers, we sometimes try the introduction of some valueless queen, which, if we succeed in introducing, we afterwards easily supersede by a good one. It is also advisable to introduce a sheet of brood in all stages at the same time. Many times besides all this, we take all the bees clean from the hive, carry them off 10 to 40 rods and scatter them around on the leaves or grass, that is if the hive has been queenless long enough that the bees all know the way home. The fertile worker is apt to never return, or at least we have no more trouble from her.

5. Our experiments have prejudiced us against the flat-bottom foundation. My impression is that most of our experienced bee-keepers prefer the natural base, though some still adhere to the flat-bottom.

6. Of almost any supply dealer, and I wish here to say that in my judgment the Parker fastener is yet the best device known for fastening foundation into sections.

How to Tell a Fertile Worker.

Will Mr. Heddon please explain the best way to tell a fertile worker, and also the best way to get rid of them, through "What and How" in the BEE JOURNAL. A. H. GROIN.
Elgin, Ill.

ANSWER.—I know no way to distinguish a fertile worker from other workers, unless you catch them in the act of laying, which is very seldom done. "The best way to get rid of them," see reply to Mr. Bush, and I may also add that it helps to change stands of the fertile worker colony and a good one in normal condition. I would advise this latter aid, however, only when honey was flowing plentifully.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00, or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper, shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter, on your label, notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a statement of account every week.

Trial Trip—25 Cents.

As the season for Fairs has arrived, and wishing to be able to reach several thousands of the old-fashioned bee-men, and by the aid of the BEE JOURNAL to lift them up to higher ground, adopting newer methods and progressive ideas, we make the following very liberal offer: We will send the Weekly BEE JOURNAL *three months on trial, for 25 cents*. In order to pay for getting up Clubs, we will give a copy of Fisher's Grain Tables, or Scribner's Lumber and Log Book, to anyone who will send us five trial subscriptions (with \$1.25); for a club of *ten* we will give a cloth copy of Bees and Honey; for a club of 15, a cloth copy of the 7th edition of Cook's Manual of the Apiary; for a club of 25, we will present both the Manual and Bees and Honey. If any one wants these Books for nothing, here is an excellent opportunity to get them for a little exertion.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
" 100 colonies (220 pages)..... 1 50
" 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

Do not send coins in a letter. It is dangerous and increases the postage unnecessarily. Always send postage stamps, for fractions of a dollar, and, if you can get them—one-cent stamps; if not, any denomination of postage stamps will do.

Special Notice.—We will, hereafter, supply the Weekly BEE JOURNAL for one year, and the seventh edition of Prof. Cook's Manual of the Apiary, bound in fine cloth, for \$2.75, or the Monthly Bee Journal, and the Manual in cloth for \$1.75. As this offer will soon be withdrawn, those who desire it should send for the book *at once*.

Honey and Beeswax Market

OFFICE OF AMERICAN BEE JOURNAL.
Monday, 10 a. m., Sept. 17, 1883.

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The demand for extracted honey is exceedingly dull; for comb honey, only fair; arrivals are plentiful. Stocks are large in the hands of corn merchants and others. Our own supply is larger than ever, and, for the present, we cannot compete with commission merchants. We may have to offer lower figures. Our prices so far were 75c. for extracted, and 14@16c. for comb honey on arrival.

BEEWAX—Arrivals of beeswax are good at 25@28c., and the demand is fair.

CHAS. F. MUTH.

NEW YORK.

HONEY—White clover and basswood in 1 and 2 lb. sections, 15c. Dark and second quality, 14c.; extracted white clover in kegs and barrels, 11c.; dark, 8c.

BEEWAX—Prime yellow, 30@31c.

H. K. & F. B. THURBER & CO.

CHICAGO.

HONEY—Comb honey has been bought with more freedom this week, and prices of last week have been fully sustained. The cool weather has started up the usual fall trade, and activity is the order of the hour. In selecting out the best consignments (with the exception of one round lot taken by merchants from Dakota Territory), our demand is chiefly local. Extracted honey has not been sought for to any extent, yet there is an improvement over last week in the amount sold. Comb honey, extra white 1 lb. sections, 15c.; comb honey, extra white 1 1/2 to 2 lb. sections, 15@17c.

BEEWAX—Steady and quiet, at 25@35c., as to color, etc.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—There is a moderate supply of comb and extracted of common quality, but offerings of extra choice comb are very light. The sales being effected are within range of unchanged figures. White to extra white comb, 16@20c.; dark to good, 10@13 1/2c.; extracted white to extra white, 7 1/2@8 1/2c.; dark and candied, 6 1/2@7c.

BEEWAX—Wholesale, 27@28c.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Some little inquiry for choice comb, from grocers, at 14@16c. In fancy packages, but little or no demand otherwise. Offerings are liberal of strained and extracted, and dull at 6 1/2@7c. Old and dark comb nominally cheap.

BEEWAX—Was selling at 25@26c.

W. T. ANDERSON & CO., 104 N. 3d Street.

CLEVELAND.

HONEY—Comes very slowly and sells as fast as it comes at 18@19c. for best white in 1 lb. sections, and 17@18c. for 2 lb. sections. Second quality is very slow. Extracted usually sells very slowly in our market; as yet, no extracted has been received.

BEEWAX—None in Market.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—We quote our market at 18@20c. for 1 lb. white clover; 18@19c. for 2 lb. white clover. Extracted is in good supply, and selling from 9@10c.

BEEWAX—Our supply is gone; we have none to quote.

BLAKE & RIPLEY, 57 Chatham Street.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid,

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Books at Fairs.—Those who make an exhibit at Fairs will find that an assortment of Books and Pamphlets would sell and leave them a profit for handling. We will send such, postage prepaid, at 25 per cent. discount; or if the purchaser pays express charges, we will supply any of our own publications at 40 per cent. discount.

Emerson Binders.—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

The new two cent rate of postage for letters goes into effect on October 1. Three cent postage stamps will then be but little used. For all fractions of a dollar sent to us hereafter we should prefer either one-cent, or else five or ten-cent postage stamps. Do not send coins in any letter.

Fairs.—To any one exhibiting at Fairs, we will send samples of the BEE JOURNAL and a colored Poster, to aid in getting up a club. The Premiums we offer will pay them for so doing. For a club of 8 subscribers to the Monthly BEE JOURNAL, or 4 Weekly, we will present Dzierzon's Rational Bee-Keeping, price \$2.00.

Sample Copies of the AMERICAN BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

BEES and HONEY,

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS C. NEWMAN.

Editor of the Weekly Bee Journal.

925 West Madison Street, Chicago, Ill.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most money in its best and most attractive condition.

Appreciative Notices.

A neat and abundantly illustrated hand-book of apiculture.—American Agriculturist, N. Y.

Its chapter on marketing honey is worth many times its cost.—Citizen, Pulaski, Tenn.

Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of every beginner with bees.—News, Keithsburg, Ill.

Valuable for all who are interested in the care and management of bees.—Dem., Allegan, Mich.

Engravings are fine. Gotten up in the best style, and is cheap at the price.—Farmer, Cleveland, O.

Carefully prepared for beginners.—Farmers' Cabinet, Amherst, N. H.

A very valuable work to those engaged in bee-raising.—News, Prairie City, Iowa.

We advise all who keep bees to send for this excellent work.—Journal, Louisiana, Mo.

Carefully prepared, and of vast importance to bee-raisers.—Indianian, Clinton, Ind.

New and valuable, and embellished with 109 beautiful engravings.—Democrat, Salem, Ind.

Much practical useful information, in a cheap form.—Daily Standard, New Bedford, Mass.

The most perfect work for the price ever yet produced on the subject of bee-culture.—Anti-Monopolist, Lebanon, Mo.

A manual, containing all the newest discoveries in the management of these little workers.—Plain Dealer, St. Lawrence, N. Y.

Full of practical instruction, that no one who contemplates keeping bees can do without.—Farmers' Journal, Louisville, Ky.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.

It embraces every subject that can interest the beginner in bee-culture. The engravings perfectly illustrate the text.—Farm and Fireside, Springfield, O.

Embraces every subject of interest in the apiary, giving very thorough details of the management and manipulations necessary to make bee-keeping a success.—Farm, Longmont, Colo.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

Describes all the newest discoveries in the art, by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive shape.—Signal, Napoleon, O.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—Farmer, Lancaster, Pa.

PRICE—Bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

THOMAS C. NEWMAN,

925 W. Madison St., Chicago, Ill.

A Liberal Discount to Dealers by the Dozen or Hundred.

May we ask you, dear reader, to speak a good word for the BEE JOURNAL to neighbors who keep bees, and send on at least one new subscription with your own? Our premium, "Bees and Honey," in cloth, for one new subscriber to the Weekly, or two for the Monthly, besides your own subscription to either edition, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

OLDEST BEE PAPER
IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED
IN 1861

VOL. XIX.

CHICAGO, ILL., SEPTEMBER 26, 1883.

No. 39.

THE AMERICAN BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

The North American Bee-Keepers' Association.

The representative of the BEE JOURNAL, Mr. W. F. Clarke, furnishes the following report of the proceedings of the Convention:

The Association met in the City Hall, Toronto, Ont., on Tuesday, Sept. 18, at 10 a. m., the President, D. A. Jones, in the chair.

There was a large attendance for the initial meeting, but as the Secretary, Mr. A. I. Root, had not yet arrived, routine business was deferred, and reports were invited from various parts of the Continent, which were listened to with much interest. [These Reports, together with the address of the President and some other papers and discussions in detail, will be given in our next issue.—ED.]

This meeting of the Association had some peculiar features:

1. It was held for the first time in the history of the Association on Canadian soil. From the outset this body has been international and continental, and comprised both countries. Canadian bee-keepers have been delighted to have this meeting on their side of the lines, and the feeling manifested all round was very cordial. The term "brother" was so uniformly employed, that one might easily have imagined that the gathering was an Ecclesiastical rather than an apicultural one, but for the topics discussed.

2. The almost total absence of papers specially prepared for the convention. In the past there have probably been too many papers; this time there were too few. A little more

heavy ballast would probably have steadied the ship, which sometimes appeared in danger of keeling over with exuberance. The discussions were occasionally rather superficial for want of being opened by a thorough treatment of important topics. Most of the "vexed questions" among bee-keepers got the go-by, and the meeting had more the character of a happy reunion, than of a debating society. Many points of interest to advanced bee-keepers failed to come up, and scarcely any strong diversities of opinion presented themselves. Two or three papers from men who have strong convictions on certain topics, would have at least made more variety.

3. There was no committee on business, or indeed on anything. How the convention was run, or whether it ran alone, deponent sayeth not. A prominent member asked on the third day, "who is running this thing?" but though he spoke out loud in meeting, there was no reply. It will probably remain an unexplored and unexplained mystery to most of the members, how the machine was guided. To all appearance, it went like a balloon, and was influenced by unseen, aerial currents, but at any rate, if it were so, the aeronauts had a very pleasant voyage, and got down to solid ground safely. All present were unanimous in declaring that they had "a good time."

4. Last, but not least, there was the presence of the Nestor of modern bee-keeping, Rev. L. L. Langstroth, the state of whose health has not admitted of his attendance at such a meeting since 1870. His friends all over the Continent of North America, and elsewhere, will be glad to learn that he declares himself to be better in health than he has been for twenty years. He spoke with great force and effect, several times proving himself, "the old man eloquent." His presence added a great charm to the meeting, as well it might, and did much to give

it that character of a happy reunion to which allusion has already been made.

AFTERNOON SESSION.

A large number convened in the afternoon, when it was thought advisable to discuss miscellaneous questions, pending the arrival of the Secretary, and other expected members of the Association. The first asked was the most desirable thickness of comb foundation for section boxes. Prof. Cook, Dr. Miller, Messrs. Vandervoort, Taylor, Jones, and several others gave their views, which were pretty unanimous as to about 7 square feet per pound being the most desirable size. "What is the cause of fertile workers being developed?" was next discussed, and some difference of opinion made it lively. Prof. Cook thought the desire for eggs in the absence of a queen, stimulated the laying propensity in the workers. Dr. Brown was of the opinion that food had much to do with the matter, and read a brief paper giving his observations concerning fertile workers for two or three years past, confirmatory of that opinion.

President Jones said, he had seen abundant proof in his apiary, that feeding had nothing whatever to do with developing the laying instinct in workers. After a free interchange of opinions, the subject was dropped, whereupon the question of bee forage was introduced. This created much interest, many of the members present giving their observation and experience in relation to honey-producing plants. The general feeling seemed to be that this matter was one of great practical importance, to which bee-keepers must give more attention hereafter. The next question propounded was, "What precautions are necessary to prevent young queens mistaking their hives on returning from their bridal tour?" Dr. Andrews would set his hives at varying angles. President Jones thought no precautions were necessary provided the hives were not too close to each other. They should be fully 6 feet apart. One member suggested the use of a narrow board in front of hives, from which young queens might issue. "What is the most desirable width for section boxes?" was the next question. Mr. Pettit said, the best comb honey at the Toronto Exhibition was in sections about an inch and a half in width.

The President and a number of the members of the Northeastern Bee-Keepers having entered the meeting, they were introduced by the President, and asked to participate freely in the discussions. The subject of sections was then resumed, and took a wide latitude, including the question of separators, the comparative advantage of half-pound and one-pound sections, and the demands of the market. Mr. Muth went strongly against the half-pound sections, which he thought were ridiculously small. Speaking as a dealer, there was no demand for any thing so small. Prof. Cook rather mildly defended the half-pound section, and referred to Mr. Heddon's experience with it, and especially to his doing without separators. Dr. Miller had been experimenting with the half-pound sections without separators, but had been troubled with irregularity of building to an extent that interfered with packing. Mr. Pringle thought it advisable to have sections of different sizes to meet the varied demands of the market. Several others took part in the discussion, and the weight of opinion was evidently on the side of one and two-pound sections.

At this stage of the meeting, Mr. A. I. Root arrived, and a resolution was adopted arranging for a visit to the Exhibition early to-morrow morning, when the meeting adjourned until 7:30 p. m., to give opportunity for the enrollment of members and payment of annual subscriptions.

EVENING SESSION.

The Association resumed business about 8 p. m., with a greatly increased attendance. Prof. Cook, at the request of President Jones, exhibited and explained the use of a brush devised by T. J. Cook, of New Point, Ind., for brushing bees off combs. The Professor prefaced his remarks by stating that the inventor of this brush was no relation of his, and that he had no interest in the matter, except to call the attention of bee-keepers to what was a much better device than a goose feather, bunch of grass, or asparagus, for brushing off bees. Three samples had been sent to the Convention, and were on the table for inspection. Having used the brush with much satisfaction, he was pleased to recommend it to other bee-keepers. Dr. Miller and Mr. Corneil joined in the recommendation.

The discussion of questions was then resumed by considering the best method of getting the bees out of section boxes, at the close of the honey season. Dr. Miller's plan was to raise the section case a little, lay a cloth between it and the hive, leaving one corner open so that the bees can go down into the body of the hive during the night, which they will do if the cover is left off the hive. Then remove the section case in the early morning. Mr. Bacon practiced taking the sections into a room and leaving the window open, so that the bees could return to their hive.

The subject of curing or evaporating extracted honey was next taken up. Mr. Poppleton, on being called

upon said, he lived in a dry climate where no particular means were needed, but farther South precautions must be taken or honey would become sour. He was of opinion that the sun was the best evaporating agent, when it was necessary to do any thing with that object in view. Mr. Corneil was of opinion that the first point to settle was whether the honey needed evaporation. If it did, he, too, was of the opinion that the sun was the best agent for doing it. Mr. A. I. Root gave a very full account of his experience with different qualities and varying thickness of honey. Mr. McKnight confirmed Mr. Root's testimony, and said that a lot of honey stored in a tank had become so watery on top that some of his family suspected that honey had been stolen, and water added. He knew better, as some of the honey had been gathered in a rainy time. A number of testimonies were given, all going to show the impolicy of putting unripe honey on the market. This topic branched out into a discussion of candied honey, the best means of re-liquefying it, and a variety of other details. A question was now raised which excited a lively expression of opinion, and illustrated the maxim that "doctors differ." It was, "If I have 100 colonies, spring count, and wish to increase to 150, shall I do best to make the increase before the honey harvest, during the honey harvest, or at the close of the honey harvest?"

Prof. Cook replied, "Before, if possible; if not, afterwards; during, never." Dr. Miller said, "During, always," and there was a running fire of opinions *pro* and *con*, which, at last, settled down to a good discussion on the point. Mr. Poppleton apparently carrying the day by contending that increase should be carried on from early spring, right along, and be completed by the end of the honey harvest. The subject of tiering up sections was next discussed, whether it should be done under or on top. Strange to say, both methods had its advocates. Mr. Hall, the largest producer of comb honey in Ontario, puts the empty sections on top. Dr. Miller had come to the same view. At this juncture, Mr. Heddon was greatly needed, but was not forthcoming.

The comparative advantage of one and two story hives for extracting honey was then brought up by a question. In the course of the discussion, speakers branched out into a general statement of experience with hives, and a mixing up of extracted and comb productions in a somewhat confusing manner. The question which is the best material for spreading in front of bee hives led to a variety of opinions. Some one said, "Mr. Root recommends sawdust." Mr. R. replied, "I once did, but I do not now. I find the best material to be a foundation of cinder, and a thin coating of the whitest sand on top." President Jones recommended leached ashes. A member said it created too rank a growth of grass and weeds. Another member suggested salt.

At this stage, Dr. Miller offered a resolution that the editors of bee

periodicals be requested to encourage correspondents to append to their signatures a statement of the number of colonies owned by them in the spring, and the number owned at the time of wintering. The resolution was hurriedly put and declared carried without opportunity of discussion.

The President then informed the meeting that Rev. L. L. Langstroth had arrived, was at the Queen's Hotel, and would join the party to-morrow morning for the Exhibition grounds. The meeting then adjourned.

SECOND DAY.

Pursuant to resolution adopted yesterday, the members of the Association took steamer for the Exhibition grounds, about three miles from the city, to see, first of all, the Honey Show, and then any other objects of interest which had special attractions for them. It may be observed that a great Industrial Exhibition lasting two weeks is now in progress, and the Honey Show is one of its Departments.

It is held in a building about 40x120, which is entirely devoted to this purpose, and is filled from end to end with the finest display of honey ever collected on this Continent. A little detail will give some idea of the scene. D. A. Jones, of Beeton, has, of course, the largest exhibit. At one end of the building, he has a pyramid of cans, ranging from two ounces to five pounds in capacity, the whole forming a little mountain of honey, 41 feet 6 inches in length by 14 feet in breadth, and towering far above the heads of visitors. In the centre of the building a cone of smaller circumference, but rising to a greater height, is similarly constructed. Above this pyramid floats a variety of flags, and above all the porcelain globe of a powerful electric light spreads at night the brightness of noonday over the whole interior of the building. Great boxes of honey are piled against the wall, and over them, and on the floor are 80 barrels in all of the luscious liquid.

In all, Mr. Jones has about 50,000 pounds of honey in the building. Mr. Hall of Woodstock, Ont., is the next largest exhibitor, and shows an imposing array of white combs rising far upwards, and varied every 2 feet by buttresses of extracted honey in gaily labelled cans, extending far along one side of the building. Mr. Hall has on display about 9,000 pounds of honey in the comb, and about 13,000 extracted. Martin Emizh, of Holbrook, Oxford county, takes the palm for the nicest exhibit of comb honey. It is remarkably uniform and well filled out in the comb. Much admiration was expressed of this exhibit, which comprised about 4,000 pounds. Mr. Ramer, of Cedar Grove, Mr. Goodyear, of Woodstock, G. B. Jones, of Brantford, W. C. Wells, of Philipstown, Ont., Messrs. Granger & Duke, of Deer Park, and others contribute to make up the fine display, which here presents itself to the eyes of the visitors.

To many, a far more interesting and attractive object than the honey

show, was presented in the person of the Rev. L. L. Langstroth, who held a sort of extempore levee in the building, and went through a somewhat fatiguing ordeal in the way of shaking hands with the multitude of bee keepers and others who were introduced to him by President Jones and Wm. F. Clarke. It became necessary after awhile to withdraw the venerable apiarist from the scene that he might rest somewhat, and be in time for the public meeting. Meantime, a general reunion of bee-keepers went on in and around the extensive exhibition building. Few seemed to feel much interest in the other departments to be found on the grounds, and there was ample proof of the correctness of a remark made by Mr. Langstroth, that of all classes he had met with none were so enthusiastic in the line of their calling as bee-keepers.

The convention was broken up into a multitude of little conventions, and all seemed to enjoy the opportunity of social intercourse presented. Attention was not confined to the interior of the building, but extended to a survey of the bee hives, colonies of different races of bees, and the large variety of bee requisites to be found adjacent out-of-doors. To attempt a specification of all the numerous articles on exhibition would extend this report to a length that would be unsuitable, and should anything be undesignedly omitted, the inventor or owner would feel himself slighted.

AFTERNOON SESSION.

The Association resumed in the City Hall. Miscellaneous questions were the first order of business.

Dr. Thom asked if any one had experienced evil effects to the eye-sight from the use bee-veils. This led to a general discussion on the best material for bee-veils; several declaring in favor of black, and some in favor of white gauze. A few spoke in approval of wire netting, while others urged objections against it. A. I. Root said he had experimented, and used many endeavors to obtain a wire cloth that would have all the advantages of wire cloth, without any of its disadvantages, but had not succeeded. On the whole, he would recommend bee-keepers not to use veils unless obliged to do so. Mr. Corneil did not think veils did any particular injury to the eye-sight, otherwise ladies would not wear them so extensively. President Jones recommended the use of the finest Brussels lace. Mr. Bowers thought the veil might be made of any cheap suitable material, with a window of the very best silk bobbinet.

Mr. C. W. Young brought up the subject of collecting statistics. He suggested that the local press should be more generally utilized for the purpose of conveying information about apiculture. A general discussion on the importance and yet difficulty of obtaining statistics ensued. President Clarke, of the Northeastern Association, said they had found it impossible to get statistics even from prominent men, in any year, when

they happened to be unsuccessful. For that reason the Northeastern Association had discontinued the publication of its reports.

The question of the proper width of sections was then resumed, and talked over at some length, but nothing particularly new was elicited.

At this juncture, Rev. L. L. Langstroth entered the convention, was received with a rising expression of welcome by the members, and conducted by the President to the Mayor's chair, as a token of respect, amid loud and prolonged cheers.

The President's address was then delivered. It consisted mainly of welcoming words in regard to the meeting of the Association, together with a brief resume of the honey season just past. Prof. Cook, Messrs. Bacon, A. I. Root, Pierce, and Dr. Miller made responses, gratefully appreciating the welcome which had been accorded to the Americans, and the pleasure it had given them to visit Toronto, and attend this convention. By special request of President Jones, Mr. Langstroth addressed the meeting. He gave an interesting account of the way he was led into bee-keeping, and of his early mistakes and difficulties; related the manner in which he had been led to invent the movable frame, and the circumstances connected with its general adoption; and stated a number of interesting facts bearing on the history and progress of bee-keeping. At the close of Mr. Langstroth's address, the Association proceeded to elect officers.

On motion of Prof. Cook, Rev. L. L. Langstroth was chosen President. The motion was carried by a standing vote. L. C. Root, of New York, was appointed First Vice-President; Dr. C. C. Miller, of Illinois, Secretary, and C. F. Muth, of Ohio, was re-appointed Treasurer. A list of Vice-Presidents for the several States and Provinces was also made up.

The question of the next place of meeting was then taken up. President Clarke, of the Northeastern Bee-Keepers' Association, on behalf of New York, invited the members to Rochester next year. Dr. Miller conveyed the request of the Northwestern Bee-Keepers' Association to appoint the next annual meeting at Chicago. On motion of Prof. Cook, Rochester was chosen as the next place of meeting. The date was left to be fixed by the executive committee.

EVENING SESSION.

Business resumed. Vice-President Cook in the Chair. The discussion of miscellaneous questions was made the first order of the evening. Two enquiries concerning foul brood were laid on the table.

"Is it advisable to clip the wings of queen bees?" was next asked. A lively discussion arose, proving the house to be considerably divided on the point. One member announced himself "a clipper." Another said he might be a clip, but he was not a clipper. The reasons for and against were pretty fully stated.

"At what age should a queen be superseded?" was the next question. Mr. Hall thought no age could be fixed. Bees were like human beings, some were young when they were old, and others were old when they were young. Queens should be watched, and superseded when not working satisfactorily. Mr. Langstroth would not fix any unvarying time, but he had found two seasons, on an average, the term of a queen's greatest prolificacy. After that, they would show signs of failure. It was a remarkable feature in the Italians, that they were quick to notice signs of failure in a queen, and took early measures to supersede her. That alone was sufficient to recommend them.

The best method of feeding in the fall was next considered. Mr. Jones, on being called up, advised the use of the best granulated sugar, in the proportion of two pounds of sugar to one of water. The discussion soon branched off so as to take in the topic of feeders. Mr. Langstroth and others discouraged the use of fancy feeders. Mr. Jones tilts the front of the hive a little, and pours the syrup on to the bottom board, from which the bees take it up very quickly. Mr. Locke suggested that all bee-keepers could not tilt their hives, and hence, some kind of a feeder became necessary. He recommended the use of a Mason fruit jar furnished with a tin cover perforated with a number of holes. Filled with syrup and inverted, this made a good feeder.

The treatment of wax then occupied the attention of the meeting. Boiled down, the discussion amounted to this: that great pains ought to be taken to purify wax; that to secure this it was necessary to keep wax in a melted condition for several hours, long enough indeed to allow all sediment to settle to the bottom. A. I. Root said he had worked up 12 or 14 tons of wax this season, and pursued substantially this plan. He made three qualities of foundation. Wax from the top of the tanks was used for section foundation, being the whitest; the second and third qualities being darker, were sold at less price for brood comb foundation.

At the instance of Prof. Cook, it was decided that the rest of the evening be given to Rev. L. L. Langstroth for a talk on old bee books. This was very interesting. Beginning with Aristotle, Virgil, Columella, and Pliny, on each of whose knowledge of bees remarks were made. The speaker came down to books that appeared in the days of the Stuarts and the Commonwealth, the former entitled "The Monarchy of Bees," and the latter, "The Reformed Commonwealth of Bees;" indicating the different political circumstances of the times in which they were written. Some extracts were given from these books, and Mr. Langstroth expressed the hope that he might yet be able to publish a work embodying these and other observations on old bee books, which would show modern bee-keepers that ancient apiarists knew a great deal more about bees than they

usually got credit for. Even the advanced bee-keepers of to-day might learn much from them.

At adjournment, it was decided that the convention should close with to-morrow afternoon's session.

THIRD DAY.

The Association met at 9 A. M., Vice-President Cook in the chair. About 100 members were present at the opening of the morning session. Discussion of questions was resumed, the first being, "What is the best way of preserving surplus combs from the ravages of the moth?"

Judge Andrews thought there was no time when there were not eggs of the bee-moth in comb. Heat would develop them. The combs should be carefully kept in some cool place.

Dr. Brown found it necessary in the warm climate of Georgia, to have a comb repository, which he kept fumigated with sulphur.

Mr. Jones places his frames about an inch or an inch and a half apart, and if allowed to hang all winter, exposed to frost, there will be no trouble from the moth. He recommended that the joists of the honey-house overhead, be set just the right width to hang the frames on rabbits, tacked to the lower edge of the joists.

Prof. Cook summed up that the moth would never trouble combs while sufficiently covered with bees; not so protected, the moth will certainly be developed; hence strong colonies were the best antidote to this insect. Comb should not be left lying loose around the apiary, but should be stored out of reach of the moth miller, and kept in a cool place.

The right temperature at which to winter bees was the next question considered.

Prof. Cook would say from 40 to 45 degrees.

Dr. Miller called attention to the varying markings of thermometers, which rendered it undesirable to fix very exactly the degree of temperature to be maintained. He would advise watching the bees, and keeping them in that temperature in which they preserved perfect quietude.

Mr. Jones used to think 40° was about the right temperature, afterwards he thought it should be 43° to 45°; but he had come to the conclusion that it was better the temperature should go higher than 45° than under 40°, especially during the latter part of the winter. He had frequently had his houses go above 50°; in one case, accidentally, a house went up as high as 70° without any ill effects. More harm comes of letting the temperature go too low, than too high.

The general subject of wintering bees was then taken up.

A. I. Root was not going into the subject at length, but wished to mention a case in which the bees had been given access to water by means of a sponge, with good results.

Prof. Cook had followed that example of giving the bees a drink, but every colony so treated had turned out unsatisfactorily.

Mr. Jones did not believe in keeping hotel in a bee-house. He had never

had any trouble with his bees being too dry. Excess of moisture had often troubled him. While speaking of wintering, he would strongly recommend the use of a bee-house with hollow walls, of a foot or more in thickness, filled in with sawdust or some similar material. If you have 100 colonies, and were sure they would winter safely out-doors, you may calculate that it will cost \$1.00 per colony, or \$100 more to winter out-doors than in-doors; it therefore pays to have a house. Instead of packing hives, he would pack the house the hives are stored in.

A running fire of questions was here opened on Mr. Jones in regard to various particulars relative to his method of wintering. The discussion gradually drifted off into the subject of ventilation, on which a great variety of opinions was expressed.

Dr. Miller frankly confessed that even yet he knew nothing definite about wintering. Circumstances and conditions differ so greatly, that what succeeds one season, fails another.

A member spoke of the unsatisfactory use of enamelled cloth in winter.

A. I. Root said it was a mistake to suppose that the cloth was to be used in all seasons. In winter he used burlap, a coarse species of bagging, which the bees could look through if they wanted to. He also used woven slats. He thought either of these with a packing of forest leaves on top, such as Mr. Dadant uses, make a good winter covering.

Mr. McKnight had tried various packing materials, but found nothing so good as the ground cork, in which grapes are packed when shipped from France. He found no difficulty in getting all he wanted from the grocers in his town.

A number of members gave their views of packing for winter, and various materials were suggested for the purpose.

At this juncture, A. R. Boswell Esq., Mayor of Toronto, entered the meeting, and was received with warm cheering. A vote of thanks was then enthusiastically passed, expressing the gratitude of the Association to the Mayor and City Council for the use of the City Hall free of cost for these meetings.

The Mayor replied, cordially welcoming the Association to Toronto, especially those members who have come across the border. He referred to the grand honey display, and the rapid progress bee-keeping was making, and wished the Association the greatest prosperity.

On motion of D. A. Jones, seconded by Dr. C. C. Miller, it was Resolved unanimously, That in the opinion of this meeting, the time has fully come for a recognition of the claims of bee-culture by its being taught in all the agricultural colleges throughout the continent of North America.

In connection with this resolution, a paper was, at the call of the meeting, read by Wm. F. Clarke. It was the only paper specially prepared for the Convention, yet presented.

An interesting episode then took place in the form of an address, from

the Ontario Bee-Keepers' Association, to Rev. L. L. Langstroth, accompanied with a purse containing \$56 as a trifling token of esteem.

Mr. Langstroth replied in a feeling manner, and referred at some length to the manner in which his motives had been misunderstood many times, and to his earnest wish to promote by all honest means, the interests of apiculture.

Vice-President Cook expressed the great pleasure it had given him to attend this Convention, and to witness the harmony and good feeling which had prevailed. He was especially gratified at the presence of Mr. Langstroth, and the manifestations of grateful respect to him on all hands. In view of the many auspicious circumstances which had characterized this meeting, he proposed that all should join in singing the Doxology. This was done very heartily, after which Rev. L. L. Langstroth pronounced the Benediction.

As a number of the members were about leaving, there was much cordial hand-shaking at the close of this session.

AFTERNOON SESSION.

The Association resumed at 2 P. M., Dr. Miller in the chair. There was still a large attendance, though a number had left for home.

The first subject taken up was that of frames.

Mr. Hart complained that many of the frames he had obtained from the North were too slender, sagged too much, and sometimes broke.

Dr. Miller expressed surprise at this, and said he had experienced no such trouble.

Mr. Langstroth described a frame with triangular corner supports for the top-bar. He thought this could be made stronger than any other.

Mr. Muth said he preferred the frame he now used, which had a heavy top-bar, the whole underside of which was beveled.

Some other members expressed their views on the frame question, but all agreed that it was desirable to have sufficient strength in the top-bar to stiffen the whole.

The question, what were the best barrels for shipping honey? was discussed.

Mr. Muth said a great deal of honey was lost by being put into improper barrels. They were often too weak and slender. Second-hand barrels were often used, and there was constant loss when this was done. Honey was heavy, and needed a strong package; he preferred cypress. Oak made good barrels when well coopered, but badly made, they were the worst of all for leaking.

Mr. Jones agreed with Mr. Muth, but thought white-ash preferable to oak. He had been greatly troubled to get thoroughly-tight barrels.

Mr. Poppleton had found some second-hand barrels answer very well.

A resolution was introduced by Mr. Pettit, seconded by Mr. Muth, pledging the Association to do all in its power to remove the public prejudice against granulated honey. Consider-

able discussion arose on this resolution, which, at first, merely expressed the idea that granulated honey was "natural and good." Some wished to affirm that pure honey would always granulate. Others objected that it would not always granulate. Mr. Jones challenged any one to produce pure honey that would not granulate. Mr. Muth had kept California honey a long time, even three or four years before it granulated, but it did so at length. He had seen honey mixed with glucose that granulated to a certain extent. Mr. Jones said the pure honey would granulate, and the glucose float on top. He admitted that there was a difference in the grain; some was coarse, and some fine. After much tinkering at the resolution, it was finally adopted in the following form:

Resolved. That we as individuals and as an association do all in our power by precept and by practice to convince the public that granulated honey is natural, wholesome and desirable, and that granulation is a fine test of its purity.

Mr. Jones was requested to give an account of his method of introducing queens by the use of chloroform, which he did, and then a general discussion of queen introducing sprung up. Mr. Langstroth narrated in an interesting manner some of his early experiments in queen introduction. Among others, he tried the experiment of making a whisky syrup which he fed to the bees and the queen. They acted very much as drunken people do, but when sober, would not accept the queen.

Mr. Jones stated that the reception of a queen depends on her own behavior. If she is frightened, nervous, and uneasy, the bees will ball and dispatch her, but if she is quiet and contented, there is no trouble. The main thing, therefore, is to devise a plan by which the queen will be led to act in a natural manner. Mr. Langstroth and Judge Andrews confirmed this view.

After some further talk on the subject of queens, Dr. Brown remarked, that one and another seemed to be dropping out of the meeting, and it was desirable that there should be a general hand-shaking all round. He therefore moved, seconded by C. F. Muth, that the Association do now adjourn, to meet in Rochester, N. Y., a year hence. The motion was carried, and the convention declared adjourned, *sine die*.

 The bee-keeper who expects to keep up with the times, must make up his mind to push things, and not allow himself to be drawn along by circumstances. In order to push, one must think and plan ahead of the work to come, and have all things in readiness, so that there may be no delay in doing the work at the right time.—*Indiana Farmer*.

 To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey at Fairs, will sell almost a fabulous quantity of it.

Bee and Honey Show at Toronto.

From the Toronto *Globe* we extract the following article concerning the Bee and Honey Show and Convention:

Among the varied attractions of the Toronto Exhibition the present year, prominence may very properly be given to the annual meeting of the abovenamed society, which is to be held in the City Hall and Council Chamber on the 18th, 19th and 20th instants. As this is the first time this important organization has met on Canadian soil, the occasion was one of special interest to the bee-keepers of this country, and it is well that they should be made familiar with the origin, history, work, and aims of the society in question. It was formed at Indianapolis, Ind., December 21, 1870. As its name imports, it is international and continental in character. It was originally designed to be a national society, but Canada was represented at the initial meeting in the person of Rev. W. F. Clarke, of Guelph, who was and is, not only a prominent agriculturist, but an enthusiastic bee-keeper. At that gentleman's suggestion and request, the society was expanded in scope, so as to take in the Dominion along with the Republic. Though this is the first time the society has met in Canada, this country has had its fair share of honorable recognition by it. During the thirteen years of its existence, Canada has been thrice represented in its presidency, twice by Mr. W. F. Clarke, and once by Mr. D. A. Jones, who now worthily fills the office, and to whose influence the selection of Toronto as the place of meeting for 1883, is to be mainly attributed.

The first president of this society was the Rev. L. L. Langstroth, who may, without invidiousness, be styled the father of modern bee-keeping. His book on the "Honey Bee," and his invention of the movable frame hive, may be said to have revolutionized bee-keeping. Prior to these being presented to the public, bees were kept in a hap-hazard way. But little was known of the nature and habits of this little insect beyond the facts embodied in the well-known juvenile hymn, beginning,

"How doth the little busy bee,"

The interior economy of that wonderful miniature world—a bee hive—was well nigh unknown. Everything inside the hive was "fixed fast in fate," and inaccessible to any but its honey-gathering population. The movable frame was indeed a revolution in bee-keeping. It enabled the apiarist to control the operations of the industrious little workers, and paved the way for the extractor, queen-breeding, and various other improvements, which have combined to make bee-keeping, as now carried on, one of the wonders of the age we live in. Mr. Langstroth still lives to witness the marvelous progress of the pursuit for which he has done so much; and though in poor health, and bending under the weight of years, intends being present at the approaching

meeting. There are few who are aware of the great services this remarkable man has rendered to apiculture, who will not feel that the opportunity of seeing and hearing the Nestor of modern bee-keeping, will be of itself sufficient inducement to secure their attendance and ample reward for it.

Mr. Langstroth was fitly succeeded in the Presidency of the Society by the late Moses Quinby, whose work on the "Mysteries of Bee-Keeping" ably seconded the teachings of its predecessor, and whose labors in the advancement of this industry were hardly second to those of Mr. Langstroth. Mr. Langstroth was only able to spare moments of leisure from the duties of a higher calling. These he faithfully devoted to the advancement of his favorite secular pursuit, and few men can point to such a record as his, resulting from masterly and diligent use of leisure. But Mr. Quinby devoted his whole time and attention to bee-keeping, and was one of the first, if not the very first, to exalt this pursuit into a business. Encouraged by his example, and guided by his teachings, others concentrated their energies on this industry until it became as much a distinct and special avocation as any other. Both Mr. Langstroth and Mr. Quinby labored for the advancement of apiculture with a most unselfish zeal, and while others were incessantly plying the public with patented fixtures, generously gave the fruits of their thought and toil to the world at large. They might both have become rich had they secured to themselves, as they might have justly done, royalties on their discoveries and inventions, but they toiled in self-forgetfulness, and apiculture owes them a debt of gratitude which, it is safe to say, never can be repaid.

It would be too long a detail to enumerate what the North American Bee-Keepers' Society has done toward the advancement of the industry for whose development it has worked. But this much must in all justice be said for it: that it has brought together the leading bee keepers of the Continent in yearly conclave, and their comparison of notes has been of incalculable advantage to themselves and to the apicultural public in general. Among other benefits that have resulted from this, the field of apiculture has been cleared of a vast number of impositions and shams, and bee-keeping has been exalted to a compacted science and an established industry.

THE AMERICAN BEE JOURNAL, published at Chicago, Ill., is, without question, the leading apicultural journal of the world. Its existence to-day is due to the North American Bee-Keepers' Society, established in 1861, by Samuel Wagner, a name of high renown in the annals of American apiculture. It was on the lamented death of that gentleman, in February, 1872, in eminent danger of extinction. At the next annual meeting of the Society, the future of this important periodical was an anxious topic of discussion. The then President of

the Society, Rev. W. F. Clarke was urged to take the enterprise in hand, and encouraged by the pledged co-operation of leading members of the Society, did so. The JOURNAL was removed from Washington, D. C., its former place of publication, to Chicago, and the foundation laid of its subsequent prosperity. Mr. Clarke gave it his personal supervision for a year, when it passed into the hands of Mr. Thomas G. Newman, who has guided its destinies ever since, and under whose able management it has become the most potent literary agency for the promotion of bee-keeping at present in existence. If the Society had accomplished nothing more for apiculture than the preservation of this invaluable periodical, it would deserve to live and prosper.

The great lights of North American bee-keeping are expected at the approaching annual meeting. It is conceded that this Continent now leads the world in apicultural progress. The apiarists of all other countries dip their flags to North America, and Canada enjoys the proud boast of having produced the foremost of enterprising and successful bee-keepers in the person of Mr. D. A. Jones.

Among other distinguished apiculturists who intend to be present on the approaching occasion, special mention may very properly be made of Prof. A. J. Cook, whose "Manual of the Apiary" is now generally accepted as the standard work on bee-keeping. Mr. Cook is an accomplished entomologist, of which science he is professor in the Michigan Agricultural College, and in the course of his teaching makes a specialty of scientific and practical bee-keeping. He manages an experimental apiary at the college, and in this branch of study has a class of 40 students the present year. Did space permit other high authorities in bee-keeping might be named, whose presence will give interest and importance to the meeting about to be held.

It is to be hoped that all Canadian bee-keepers who can possibly attend the expected apicultural parliament will make a point of being there. Such a gathering cannot fail to give a great impetus to a large and rapidly growing rural industry. As a business bee-keeping is only in its infancy. There are vast possibilities about it yet to be developed. Without exaggeration or figure of speech—"there are millions in it." Our own Mr. Jones and other Canadian bee-keepers have shown us what can be done in this line of things. Bee-keeping offers an inviting field as a business, and as an adjunct to general farming is well worthy of receiving far wider attention. When it is considered that the income of every farm throughout the country might easily be augmented at least a hundred dollars a year, by keeping a few hives of bees, it will at once be seen what an immense increase of national wealth might be obtained were the flowers that now "waste their sweetness" duly utilized by a force of honey-gatherers large enough to collect the revenue they are so willing to yield, when

swift-winged foragers "present their little bills" for liquidation.

Bonner, the Scottish Bee-Master.

Mr. Wm. Raitt, of Blairgowrie, Scotland, gives the following in the *London Journal of Horticulture*, concerning his fellow countryman, the noted Caledonian bee-master:

Bonner's name is so much more widely known than his works on bee-keeping, that I doubt not many readers of our Journal will be glad of a few notes culled from his rare book.

Bonner was the twelfth child of a handloom weaver, of Coldingham, in Berwickshire, and seems to have received a fair education. He followed his father's occupation, and became the author of a work called "Practical Warping Made Easy." His father was an enthusiastic bee-keeper, owning as many as a dozen colonies at a time, and in good seasons made as much money by his bees, as nearly purchased oatmeal sufficient to serve his numerous family for a whole year. He purchased with a single season's wax a large quarto Bible (an expensive article in those days), "which served as a family book ever after," and his home was always supplied with honey and mead. The old man worked at his loom till within a few days of his death, in the 86th year of his age.

James, our author, was thus a born bee-master, and so great was his interest in bees that he, about the year 1765, travelled all the way to London to get a chance of conversing with the famous Wildman. The latter happened at the time to be in France, so Bonner had to return without seeing him, but he solaced himself by the possession of a rich haul of bee books, picked up on London bookstalls. He tells us he bought every book on bees that he could find. After this, and under the impulse of fresh discoveries day by day, he became so absorbed in his studies and experiments, that during the honey season he hardly took any sleep for whole weeks together. At last, in 1789, he published his first book, a "Treatise on the Management of Bees," which was well received. In succeeding years he made so many discoveries and improvements, that he resolved to embody all he knew in the larger work by which he is better known, "A New Plan for Speedily Increasing the Number of Hives in Scotland," etc. This work was issued by subscription in 1795, and was directly under the patronage of the "lords and gentlemen" of the Highland Society, the then representative of the great Agricultural Society of the present day, at whose shows the bee tent is a regular attraction.

As affording a fair contrast between the best principles of bee-keeping in the last century and those of the present day, I note a few of the more prominent of Bonner's ideas:

Honeydew.—He speaks of it as an exudation of the saccharine juices of plants, which, in some cases it un-

doubtedly is, but he seems to have no idea that the bulk of it is the excretion of aphides.

Crude and Perfect Honey.—He decidedly differs from Mr. Pettigrew in this matter, having satisfied himself that the nectar as gathered from the flowers is true honey, afterwards thickening only from the evaporation of its watery particles. I had an illustration only yesterday of one way in which bees get rid of the superfluous water in the sweets they gather. Over a large feeding trough where I was supplying my bees with sweetened water, I could see in the sunlight that almost every bee that rose with its load, ejected a spray of water. So rapidly did the water find its way from the honey sac to the excretory organs of the bee, that the moment it rose it was enabled to get rid, I should suppose, of half the weight of its burden in the form of water. I have also noticed this in the case of bees returning from the fields during the honey season.

Pollen and Wax.—Although humoring the prevailing notion that the bees gathered wax and carried it home on their legs, by culling loads of pollen and loads of wax, Bonner argues very sensibly his opinion, that wax is an exudation from the body of the bee, as milk from the cow, silk from the spider and silkworm, or wax from the human ear.

"*Smothering*" by *Brimstone*.—This he utterly condemns as "a barbarous practice" to be ever deprecated. Who would have supposed that such a practice could have continued to the present day?

Northwestern Convention.

The Northwestern Bee-Keepers' Association will hold its fourth annual convention at Owsley's Hall, N. W. corner Roby and West Madison Sts., Chicago, Ill., on Wednesday and Thursday, October 17 and 18, 1883, commencing at 10 a. m. on Wednesday and holding five sessions.

The Rev. L. L. Langstroth (the father of American apiculture) has promised to be present, and many of the most prominent apiarists of the Northwest will be there and aid in the deliberations and discussions.

This meeting will be held during the last week of the Inter-State Industrial Exposition, and reduced railroad fares may be had on nearly all the railroads. A cordial invitation is extended to bee-keepers every where to attend this annual reunion.

Meals may be obtained at the Restaurant near the Hall at 25 cts. each.

Beds may be secured at the Gault House for \$1, or at other Hotels at regular rates.

Filling Empty Combs with Syrup.

G. M. DOOLITTLE.

I have employed three different ways in filling empty combs with sugar syrup, either of which is practical in accordance with the number to be filled. The object in filling combs, is the feeding of the bees in the most desirable manner, when they need feeding. That combs well filled with honey or syrup, ready to be placed in the hive when needed, is the best way to feed bees, for any and all purposes, I think will be conceded by all. For stimulating purposes I generally set such filled combs one at a time in the centre of the brood-nest, as the bees can cover them, and the queen can fill them with eggs.

If it is thought that the bees are stimulated to a greater degree when they have to carry the syrup or honey as they do from a feeder, the filled combs can be placed at the outside of the brood-nest as far from the bees as the hive will admit of; but after trying all ways, I prefer the first given. For winter feeding, the combs should be filled as full as possible, and enough placed in the hive at one time for the wants of the bees during the time they remain inactive. Syrup, for stimulative feeding should be made by placing two pounds of confectioner's A sugar, or the same amount of granulated sugar in a tin vessel and pouring one pound of boiling water upon it, stirring till the sugar is dissolved. For winter stores I use 5 pounds of sugar to two pounds of water. Place it upon the stove until it boils, then skim. When cool, it is ready for the combs. I formerly used a little vinegar or cream tartar in the syrup to prevent crystalization, but latterly I have not, and do not see but it works just as well.

With this explanation we are ready to proceed as to how to fill the combs. If but few are to be filled, say 20 to 40, all that is needed is an extractor can, wash boiler, or any deep tin dish, in which to lay the combs, and a large tea or coffee-pot. Fix some sticks, or some arrangement to keep the combs 2 or 3 inches up from the bottom of the tin vessel, upon which the combs are to be laid. Now from your tea-pot filled with the syrup, pour a small stream into the cells of the comb, holding the tea-pot a foot or more above the comb, so the falling syrup will force the air out of the cells so they will be filled. Pass the stream over the combs until all, or nearly all the cells are filled on one side, when the comb is to be turned over and the other side filled in the same way. When filled hang the combs in your tin comb bucket (or some convenient tin thing which can be found about the house) a little while to drain,

when it is ready to be used in any spot or place the same as a frame of honey. In filling the comb the sides of the can will keep the syrup from spattering about the room, and what is caught therein can be turned into the tea-pot again, so that no loss will occur.

When 100 or more combs are to be filled, I use a watering-pot instead of the tea-pot, upon the nozzle of which is fixed a tin "rose," which slips on to the nozzle the same as does that used in spraying plants, but instead of being like the "rose" used for plants, which throws the several streams out and from the pot, this "rose" is fixed so that the under side of it is a level flat piece of tin about 2 inches square, punched full of holes, while all the rest of it is soldered up tight. Have it beveled so that it will stand just level when your watering-pot is inclined enough to pour a stream when filled one-half full of syrup, and you have it just right. Now place your empty comb in your can as before, fill your watering-pot with syrup and pour away. Instead of filling but one cell at a time, as was done with the tea-pot, this will fill a space of comb 2 inches square as quickly as the other did one or two cells, and where no very large amount or wholesale feeding is to be done, I prefer it to any other method of filling the combs with syrup.

If I have a large amount of feeding to do, as I did in June, 1878, when nearly my whole yard was in a starving condition, then either of the above plans would be too slow to be profitable. When such wholesale feeding is to be done, I proceed in this way: An extractor can is placed upon a bench about 3 feet high, and into this the syrup is poured. Previous to this I have procured a tin dish made like a baking tin the exact size of my frame, the bottom of which is punched full of holes about 1-16 of an inch in diameter, said holes being about $\frac{1}{2}$ inch apart each way. These holes should be punched from the inside of the dish, as should those in the "rose" spoken of before, so that the syrup will fall from each hole in a separate stream. Place this dish full of holes under the faucet to the can containing the syrup. Immediately under the dish place another can if you have it (if not a wash tub will answer), and you are ready for business.

If you wish to make the best time possible, have an assistant to hand you the empty combs and take the filled ones; roll up your sleeves and hold the combs near the bottom of the can, or low enough down so the air will be forced out of the cells by the falling syrup; turn the faucet so the required amount of syrup will be in the dish all the time, and you can fill the combs as fast as the assistant can hand them to you and take those filled away. When filling a large lot of combs, it is very handy to have a special rack fixed close by your can, upon which to hang your combs to drain. By placing under it several large sheets of tin set on an inclined plain, all the drip is run back into the

can again. In this way all syrup is used up without waste, and if careful no daubing of anything except the utensils necessary to be used need occur.

By the above plan no expensive feeders are to be bought or made, no room in an already crowded shop has to be taken to store such feeders, and the best of it all is the feed is placed in the combs just where the bees desire it.

P. S. I am asked what is the proper space between the bottom bar of the frames and the bottom board of the hive. I prefer $\frac{3}{8}$ of an inch, but others prefer more. Anywhere from $\frac{3}{8}$ to $\frac{1}{2}$ of an inch would be the decision of many of our best apiarists.

Borodino, N. Y., Sept. 14, 1883.

Read at the Maine Convention.

The Coming Bee.

WM. HOYT.

In considering the above subject it will be well to look at the object for which bees are kept. A few claim, that they keep bees, for the pleasure that they derive from them, but the majority of bee-keepers look to the profits that may be derived from the sale of honey, wax and bees. Now the bees that will collect the most honey, or produce the most bees, are what we are looking for.

How are we to obtain the desired result? By judicious crossing of different strains and races, and selecting those that give the best satisfaction to breed from. The bee-keeper has the advantage over stock breeders, in not having to wait years to obtain any desired point, for even in our short summers, three or more generations can be reared in a single season. Every bee-keeper who has had one-half dozen or more colonies has noticed a great difference in the amount of honey obtained from colonies that to all outward appearances were about the same in the spring, as they had the same field in which to work, of course the difference was in the bees. Now, if honey is our object, let us rear our queens from those that produce the most honey, and we shall not have to wait long before we shall see a decided increase in our yearly average per colony.

As near as I can learn, bee-keepers through this State, take one year with another, do not average over 25 pounds of honey per colony.

Are you satisfied with this? After four years experience with the yellow bees, I have become satisfied that they are better honey gatherers than the blacks. I do not wish to be understood that every colony showing yellow bands will gather more honey than the blacks, but that they will average better. Perhaps a word in regard to the different qualities shown by the different races of bees may help to determine some one in their course of action in the future.

The Italians are very prolific, industrious, beautiful and amiable, and will gather honey in times of scarcity when the blacks are idle, but prob-

ably owing to the last named quality, are more liable to suffer from dysentery and spring dwindling than the blacks.

From my own experience, and what I can learn from others, I have no doubt that the Cyprians are the best honey gatherers known; one colony in Texas gathering over 800 pounds of honey. They are remarkably prolific, and are the most beautiful bees with which I am acquainted. As to their disposition, authorities differ so much that it is hard telling anything by what we read about them. My experience with them in this respect is about as follows: While they are gathering honey from any source, or being fed, I can handle them with ease, and much faster than any other bees, and with less stings; owing to the ease with which they can be shaken from the combs, they are the best to extract from, but after the honey season is over let them alone, and at any time during the season it will not do to show any fear.

My experience with Italy Land bees is somewhat limited. I believe their principal claim is in being more prolific than any other race, and are as amiable as the Italians. In my opinion the coming bee must possess the energy and hardness of the Cyprian, and docility of the Italian, combined with the prolific qualities of the Italy Land bees.

I am not prepared at the present time to mark out any particular course for the bee-keeper to pursue, but be not content with an average of 25 pounds of surplus honey per colony, when some of our best give 100 pounds or more. The work of improving the present bee, is not destined to be the work of one person. The queen breeder will endeavor to produce whatever quality his customers call for; if they are satisfied with and call for rings and bands, the queen breeder will produce them if the purchaser demands good honey gatherers in preference to color, they will be forthcoming.

The old style of bee-keeping had one advantage over the present method, as it gave full scope to that natural law, "the survival of the fittest," as all colonies that had not succeeded in gathering a winter's supply of stores were either consigned to the brimstone pit or left to starve, while under the present management, colonies that are short of stores are fed, and every queen kept alive if possible; whether they possess any good qualities or not, thus often keeping alive queens that in the end may prove a positive injury to their owner.

In my opinion a queen should not be tolerated in an apiary unless her progeny are possessed of the following qualities:

- First.—Good honey gatherers.
- Second.—Hardy to winter.
- Third.—Easy to handle.
- Fourth.—Yellow bands.

There is much more that I would like to say upon this subject, but as I have already taken up too much of your valuable time, I will only say, do not be satisfied unless your bees

are good honey gatherers, hardy to winter, easy to handle, and possessed of yellow bands—thus hastening the arrival of the Coming Bee.

For the American Bee Journal.

Wintering on Summer Stands.

J. E. POND, JR.

To those who desire to follow the strict rule of nature, it must seem conclusive that our bees should be wintered on their summer stands. It may be argued that domesticated bees are not in a state of nature, but that argument carries little weight, as the only change made in causing them to subservise to the best interest of man, is that of furnishing them with a better and more comfortable home for themselves, and one that is more convenient to manipulate by its owner. As a matter of fact, bees are not domesticated, as are the ordinary domesticated farm animals. They are never tamed; true by selection we may rid them of bad qualities to a certain extent, and to a certain extent improve them, but till we can fully control the matter of fertilization, the work of improvement will not be complete, however satisfactory may be our approximate results. In the matter of wintering, if we assume correctly, that our bees *should* be wintered safely on summer stands, the question will at once arise, "how can this be done?" If done at all, it must necessarily be done in accordance with natural laws; and when we ascertain fully and completely just what those natural laws require, in order to accomplish this end, then the problem is solved, and the question correctly answered. Of course it cannot be expected that every colony in an apiary will be wintered successfully. Death is the great leveller, and all animate things must bow submissively to the reaper's stroke; the point is to reduce winter losses to a minimum.

In order to ascertain a remedy for disease, the first thing is to make a correct diagnosis; so with our bees, if we wish to learn how to prepare them, so they will pass safely through a long period of wintry weather, we must first learn what it is that destroys them, when no measures are taken for their safety. In some cases bees die of starvation, and that, too, when plenty of honey is contained in the frames, and in all probability this is in nine cases out of ten the cause of loss. If a sufficient amount of honey is not given to support them, when the colonies are left to the tender mercies of an inclement winter, we must expect to lose them; for that reason it is assumed, as every one now leaves sufficient stores in the hive to support the colony, that the cause of loss is the inability of the bees to reach the honey furnished them. I have been so successful in wintering, that for 16 years I have not lost a colony on standard Langstroth frames on summer stands. This I do not consider luck, but the result of following the natural laws which govern

the honey-bee, when in a state of confinement, owing to severe wintry weather.

My method of preparation assures the placing of stores in the hive, in such position that the bees can at all times and under all circumstances have access to them; also in so packing the colony that all excess of moisture will imperceptibly pass off from the hive, and not be allowed to remain and cause death, by embracing the cluster in its icy fold, when unable to generate a sufficient amount of heat to prevent it from freezing. I do not believe that any ordinary colony is destroyed by cold; I have seen a colony exposed in a box hive without any bottom board, for ten days with the thermometer standing from 5° to 14° below zero, without injury, which is proof sufficient to me of the correctness of my belief. What then does destroy the colony? My answer is excess of moisture allowed to remain in the hive, which is condensed to ice, owing to the inability of the colony to generate heat sufficient to counteract it, or else inability of the cluster to pass from one comb to another after having used up the stores within its reach. If I am correct—and who can prove that I am not?—the remedy is plain and simple. I have assumed, and still assume, that much depends upon the form of frame that is used, and claim with a large degree of pertinacity that the standard Langstroth is the correct form; this, however, is a matter of opinion which I claim the right to hold, and which I do hold only after many experiments with it, side by side with other and deeper frames. However much may depend upon the form of frame, the other conditions mentioned are essential, and I fully believe that any one who accepts and makes use of them in preparing for winter, will meet with the minimum of loss.

Foxboro, Mass., Sept. 7, 1883.

Iowa Bee-Keepers' Association.

At a meeting of the bee-keepers of Iowa, held on the State Fair grounds at Des Moines, on Wednesday evening, Sept. 5, after a full and free discussion of the bee business and its interests, it was voted to organize a State Association. Rev. O. Clute, of Iowa City, was elected president, and L. E. Cardell, of Malcom, secretary, and M. Sorrick, of Des Moines, treasurer for the ensuing year. The president, secretary and treasurer, together with Mr. O. O. Poppleton were appointed an executive committee. It was decided to hold a meeting of the association on the State Fair grounds next year, on Wednesday of the Fair week.

The project of having the society's headquarters in a tent owned by the society on the Fair grounds, was talked over. It was thought that in such a tent meetings could be held every evening during Fair week, and papers could be read, and discussions held on points of interest. It was

suggested that if bee-keepers would come to the Fair prepared to camp on the grounds near the headquarters, we could have a bee-keepers' colony for the week, which would be pleasant socially, and profitable in arousing interest in bee-keeping, and diffusing a knowledge of the subject. President Clute and his two older sons, and two of his students in bee-keeping, were so encamped this year, and found it a delightful and inexpensive method of spending the week. All persons present were requested to talk with bee-keepers in their vicinity and secure their names as members.

A vote of thanks was tendered to Rev. O. Clute for the hospitality of his tent for the meeting.

Careful Experiments with Queens.

H. L. JEFFREY.

Ever since 1876 I have been trying to solve the problem and test a probable cause and remedy for the reason that good queens taken from a hive and shipped never give their receiver as good results as their shipper had received or reported. My attention was most strongly directed in this course, in the spring of 1877, by the receiving of two queens from one of the best breeders. Both queens were shipped the same day; one by mail, in a cage, the other in a 4-frame nucleus by express. Both taken from very strong colonies; the shipper said they had 7 American frames full of brood (it was the first week in May), and were of the previous season's rearing. I introduced the one coming by mail, to a strong black colony, and built up the other. The one received by mail did scarcely anything; the other I increased up to 6 with the help of a black colony, whose queen I killed on receipt of the nucleus, giving the black bees brood from the Italian queen, as her combs had eggs and larvæ in, when they came, and I gave all the brood combs from the black colony to the Italian queen, dividing the Italian colony when the cells were 24 hours from hatching. The queen, by mail, was introduced to a very strong black colony, and given, as I then thought, an extra good chance, but she did not prove to be good for a 3-frame nucleus, and I had to help her colony from the other, all summer, and helped them for winter and some more the next spring. The next summer she did some better, but she never kept up with the nucleus queen. I, of course, said the mail was the cause. By thorough and numerous experiments, I now say it was not caused by being sent by mail, but by not being properly conditioned before being shipped, and by being put into a very strong colony when she was received.

Now I will tell you how I proved it against the two causes, and not against the cause of being carried in the mail. An accidental occurrence,

where I was going to take off a queen to introduce, but finally sent her by mail, opened a gap in the mystery. I took the queen and 2 or 3 frames of bees out of the hive and set them in a nucleus. She stood so, nearly a week (when in her own hive she had 9 Langstroth frames of brood, well filled), there being mostly young bees in the nucleus. She was sparingly fed, and consequently laid sparingly, and, of course, was in the best possible shipping condition, as was afterwards proved. This was the last of June, 1878. She was sent on a three-days journey, by mail, and was put into a two-frame nucleus, made by taking a frame of hatching brood each from two hives, and was built up to a strong colony, in the same way as the nucleus was made, as fast as she wanted room, and by the first of August, she again had 9 frames of brood of her own.

Several other queens, equally good, were caged, from strong colonies, and mailed at the same time, but they proved poor things. Why was this one as good as ever, and the others worthless? I thought over it and asked a few who had received queens to try to help me solve the mystery, but with no satisfaction. I then resolved to try some experiments to know why. For this purpose, 8 prolific queens were selected; 4 of them were put into nucleus hives; the other 4 were left as they were; in 5 or 6 days the whole 8 were caged, but marked 4 A and 4 B; all were tied in a bunch and thrown into the stage; if the package was in the way, it was kicked out of the way. In two days the package was opened, the bees fed and examined, again done up and subjected to two days more of kicking and throwing around; in no way was any pains taken to handle them carefully, but some to the opposite. After six days of such usage, as rough as could be given in the mail bag, 2 A queens and 2 B queens were given to strong colonies; the 4 remaining ones were given to nuclei, composed of 2 frames of hatching bees; the two queens given to the nuclei, in the course of a month, appeared to be as prolific as ever; the two queens given to full colonies did not do as well as before. The two taken from the strong colonies and then introduced into nuclei were doing fairly, but did not recover their former fertility that season, and the two remaining queens, not conditioned and introduced into strong colonies, were never more than half as good as they were before the experiment. This made link No. 1 in both ends of the chain—proper condition to ship and proper care to recover the journey.

The above experiment was tried during the height of the season of 1879. In 1880, three more experiments were tried, one in the spring, one in the honey flow, and one in the fall; the result showed by both careful and rough handling, that the shipping by mail or the rough handling, that the way prepared for shipping, and the way dealt with after receiving, made the most difference. Over 60 different queens were used, some just com-

mencing to lay; but the most of them were one year old.

I tried several experiments in 1881, by shipping two queens to the same person, when receiving an order for one tested queen; requesting a report of how they were for being prolific, condition the tested queen and send the other that had been laying 2 or 3 weeks right from the hive to the mail bag.

The result has always shown that a queen which has been shipped is in a convalescent state, and if put into a situation to be copiously fed on her receipt, is forced into prolificness, and like a convalescent person who is forced to hard work, of course has recovery retarded for a time, if not wholly prevented; and when valuable queens are received, they should be handled with care, and, as a rule, should not be used for breeders immediately, if the best results are expected.

Washington Depot, Conn.

For the American Bee Journal.

Mahoning Valley, B. K. Convention.

The August session of the Mahoning Valley Bee-keepers' Association was held in Grange Hall, Newton Falls, on Saturday, the 18th. The day was all that the most sanguine could wish for. A large number were present; a number of bee-keepers from abroad. A large display of honey was on exhibition, showing a creditable advancement.

At 11 o'clock President Carson called the meeting to order.

The minutes of the last meeting were approved.

The Chair then appointed the following committee on exhibits: C. G. Beardsley, William King and Warren Pierce.

There was some preliminary business which occupied the attention of the meeting for a short time, then adjournment to dinner, as usual. Sociability and an excellent dinner were important features of the short noon recess; after this had been discussed, and the committee had made their examination of honey on exhibition, our president called the afternoon session to order, and announced the questions in question box now in order:

"How many colonies can be properly kept in one locality?" Mr. Streeter thought it impossible, at present, to overstock a locality, so few were engaged in the business. Mr. Page said it was a matter of business capacity in the one that engaged in it; 5 colonies of bees would overstock some, while a hundred would not be too many for others.

"Is white clover the most profuse in honey?" Mr. Oviatt thought that white clover produced most of the honey gathered by the bees. Mr. Simon thought that basswood was the most profuse in honey, at least in his section of country.

"Is honey ripe before it is capped?" Mr. Oviatt said, he had observed that the longer honey remained in the hive the riper it gets; atmospheric influ-

ences change the condition of the honey in a measure.

"Why is it that Syrian bees do not cap their honey as soon as Italians?" Mr. Simon thought it was the field bees that capped the honey. Mr. Moore said, it was the young bees under ten days old.

"How far will bees travel to gather honey?" Mr. Page said, he had known his Italians to go $2\frac{1}{2}$ miles.

"How shall we keep our empty combs over winter?" Mr. Simon said, after a few cool nights in late fall, store them in a loft of a house or barn, so that mice will not get at them. Mr. Carson said, he left his in the hives and placed them in a cool dry place, and kept the mice from them.

"What would you do with combs that are moldy?" Mr. Page said, he put a few frames at a time into a strong colony, and let them clean them.

"Which is the best, old or new foundation to put in frames?" Mr. Carson said, that his bees work on foundation a year old, as well as new. Mr. Page preferred new. Mr. Streeter preferred the new. Mr. Hubble, of New York, has a Given press he puts the wire and foundation in at the same time. Mr. Pierce said, he had used some of this kind of frames and liked them very much.

"Can we rear as good queens artificially as by natural means?" Mr. Pierce preferred a queen reared by the natural means. It was generally concurred in by all.

"Has any one had any trouble from killing ants on the hives, and does the odor from the dead insect irritate the bees?" Mr. Oviatt had not noticed any inconvenience. Mr. Pierce said, he had been troubled a great deal by ants. Mr. Carson said, sprinkle salt around your hives.

Mr. S. Oviatt placed on exhibition one can of extracted and five one-pound sections. Mr. C. B. Page one can and two cups of extracted honey, also two cages of Italian bees. Mr. L. Carson one can of honey.

The executive committee then announced that the next meeting of the association will be held at Newton Falls on the first Saturday of November.

The Chair then appointed the following essayists for our next meeting: C. P. Page and H. A. Simon.

Adjourned to meet the first Saturday in November, at Newton Falls, O.
E. W. TURNER, Sec.

For the American Bee Journal.

Posey County, Ind., Honey Show.

J. M. HYNE.

Our Fair closed yesterday. The display of bees, honey and implements was very good. I took the first premium on the best Italian bees, also on the best Italian queen. I obtained eleven dollar's worth of premiums, and sold some implements, bees, and 300 lbs. of honey. Our show had a good effect. We have awakened up the bee interest beyond my expecta-

tion, and I think next season I shall be able to show a good report from Posey county. I think the only way to get reliable statistics, is to work up each county, say one man take charge of each county; if he does not wish to travel all over it himself, let him appoint one man in each township; surely there is one in each township that will take enough interest to see every man and get his report. Then we can have a report that will be reliable. I am willing to canvass this county. I have talked with men of some of the townships that are willing to help in the good work. The report I have taken is as follows: 42 beekeepers, 602 colonies last fall, 518 last spring, 1,055 now, 5,355 lbs. of comb honey, 4,800 lbs. of extracted honey; total, 10,155 lbs. The above report shows a poor season; at this time last season, bees were doing well. If it had rained in time, bees would have done well this season, as we had a fine prospect, but everything is drying up now, and I expect to hear of a great many box and gum hive men going out of the business, as their bees are already swarming out. My bees are in good condition for winter.

Stewartsville, Ind., Sept. 15, 1883.

SELECTIONS FROM OUR LETTER BOX

Do Not Slaughter your Crop.

Fruit is scarce. The drought and frosts will make butter high, and honey is only a partial crop, in very many places, after all of the flattering promises held out in the early part of the season, and now let us look for and get prices that will enable us to pay the high figures that we must for other products that we do not produce and must have. Here the crop is only about one-half of an average of early honey, and the late crop being a total failure, we can boast of only one-third of a crop for 1883. It is of excellent quality, however, and if we get a fair price (which we shall try hard to do), we will live, and live to hope for better results for 1884.

JAMES HEDDON.

Dowagiac, Mich., Sept. 12, 1883.

White Clover Yield.

Bees in frame hives have done very well around here this season. White clover was very abundant and yielded the finest honey I ever saw. We have no basswood around here, but have to depend on clover alone for surplus honey. We get no surplus from fall bloom. Bees in box hives did very poor, having swarmed too much. I am using the Quinby closed end frame hive, and I am well satisfied with it; have not lost any during the winters. I think I can winter them every time by packing with chaff or fine cut straw. Comb honey is selling for 18 to 20 cts.; extracted, 12½ cts., home market. GREEN R. SHIRES.

Adamsville, Ohio, Sept. 9, 1883.

100 Lbs. to the Colony.

On page 444 of the Weekly BEE JOURNAL for Sept. 5, you give me the credit in my communication of extracting 2,200 lbs. of honey, instead of 22,000 lbs. 110 lbs. to the colony is small enough when Messrs. Harriman & Adams' yield was over 200 lbs. Please correct the error.

O. M. BLANTON.

Greenville, Miss., Sept. 8, 1883.

[The omission of the cypher was an oversight of the printer, but makes a vast difference.—ED.]

Frozen Honey.

On the nights of the 8th and 9th of this month, there was frost enough here to kill most every green thing. Corn was cut very bad, and the farmers are busy cutting it up. One man told me, the other day, that his corn stubble was just alive with bees. Another said his hands felt as though he had honey daubed all over them after cutting corn. I shall watch and see how much of that kind of sweet they get; perhaps not enough to be of value to them for wintering. What I have seen of that kind of honey, is thick and has a good taste. No fall crop here yet to speak of, and the prospect is slim now of our getting any to speak of. W. H. SHIRLEY.

Glenwood, Mich., Sept. 12, 1883.

Filling Empty Combs with Syrup.

In the BEE JOURNAL, Mr. Doolittle speaks of filling empty combs with honey or sugar syrup for stimulative feeding.

1. How is it to be done?

2. What is the proper space between the bottom bar of the frames and the bottom board of the hive?

Will Mr. Doolittle please answer through the BEE JOURNAL?

T. C. GIDDINGS.

Aspen, Colo., Sept. 1, 1883.

[Replies to the above queries, may be found in Mr. Doolittle's article on page 497.—ED.]

Curious Freak of Bees.

In reply to Mr. Heddon's question, on page 433, I would say that it was the next day after they had swarmed that I looked, and from all appearances the cell was capped before they swarmed. A. RICKENBACHER.

Gahanna, Ohio, Sept. 3, 1883.

A Large Yield.

We have had the best honey season ever known in this part of the State, to my knowledge. Clover and basswood were in bloom longer than usual. From 5 colonies, spring count, I took 900 pounds of comb honey, and an increase of 13; did not take a pound from the brood-chambers, which are full of honey; will extract some when I put them in winter quarters, to make sure to leave them enough until next spring. The fall flowers yield but little nectar, because it is too dry. I have one swarm that I hived June 3, from which I took 180 pounds of

comb honey. How is that for this part of Indiana?

JOHN W. STURWOLD.

Haymond, Ind., Sept. 14, 1883.

Is Smoke Injurious to Bees?

I have recently bought and had in use a "Conqueror" bee smoker, and I am very much pleased with the power it gives me over my bees, and by its other qualities; but what I should like to know from some of your correspondents who have doubtless had more experience, is whether the very pungent smoke from the use of sound wood has no deleterious effect on the delicate larvae and eggs of the bees. Please will some of your correspondents, or Messrs. Doolittle and Heddon give their experience in the columns of your valuable JOURNAL.

JOHN MARTIN.

London, England, Sept. 8, 1883.

[Will Messrs. Doolittle, Heddon, and others please give a brief reply to the above question, as requested by Mr. Martin?—ED.]

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Alsike Clover Hay.

Will Mr. Heddon please answer the following questions through the BEE JOURNAL:

How does Alsike clover compare with red clover in the following particulars: For hay, for pasture, for fertilizing the ground, and will it pay to raise it here, where red clover does very well, but is a little inclined to freeze out in winter, not taking into consideration the bee pasturage?

G. W. WILLIAMS.

Economy, Ind., Sept. 12, 1883.

ANSWER.—Alsike clover makes better hay than red clover, it being more tender and finer. Stock prefer it either in hay or pasture. As a fertilizer, I do not consider it equal to red clover. Chemistry tells us that red clover takes the largest proportion from the atmosphere and less from the earth, making it the best fertilizer of any we have. This may be called stealing from your neighbors. My own opinion is, that there are few places in the United States where it will pay to supplant red with Alsike clover, if bee pasturage is not to be considered.

The Cass County Bee-Keepers' Association, organized on the 15th of August, will meet on the 10th of October, 1883, in Logansport, Ind. All persons interested in bees and honey are respectfully invited to come.

DE WITT BROWN, Sec.

The Bee-Keepers' Association of Central Illinois will hold its next meeting on Wednesday, Oct. 10, at 10 a. m., at 205 South Main street, city of Bloomington. All interested, in this and adjoining counties, are invited to attend.

J. L. WOLCOTT, Pres.

JAMES POINDEXTER, Sec.

The Union Kentucky Bee-Keepers' Society will hold their fall meeting in Petry's Hall, in Shelbyville, Ky., on Thursday, the 4th day of October, 1883. All bee-keepers, and the public generally, are invited to be present.

G. W. DEMAREE, Sec.

Christiansburg, Ky.

The next regular meeting of the Mahoning Valley Bee-Keepers' Association will be held at Newton Falls, O., on the first Saturday of November, 1883.

L. CARSON, Pres.

E. W. TURNER, Sec.

The quarterly meeting of the Marshall County Bee-Keepers' Association, will be held at the Court House, in Marshalltown, Iowa, on Saturday, Oct. 6, at 10.30 A. M. Subject for discussion, "Fall and Winter Care." All interested, in this and adjoining counties, are invited, for we hope to have a good meeting, and one of benefit to all.

J. W. SANDERS, Sec.

Le Grand, Iowa.

Please announce that the Iowa Central Association, will meet at Winterset, Iowa, Nov. 2, 1883.

Z. G. COOLEY, Sec. pro tem.

The Wentworth, Ont., Bee-Keepers' Association, will hold their next meeting in the Secretary's office, on the Central Fair Grounds, Hamilton, on Wednesday, the 3d of October, commencing at 1 p. m. All interested in bees and honey, are requested to attend.

ALEX. ROBERTSON, Sec., Carlisle.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price still lower, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00, or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper, shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter, on your label, notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a statement of account every week.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Books at Fairs.—Those who make an exhibit at Fairs will find that an assortment of Books and Pamphlets would sell and leave them a profit for handling. We will send such, postage prepaid, at 25 per cent. discount; or if the purchaser pays express charges, we will supply any of our own publications at 40 per cent. discount.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

The new two cent rate of postage for letters goes into effect on October 1. Three cent postage stamps will then be but little used. For all fractions of a dollar sent to us hereafter we should prefer either one-cent, or else five or ten-cent postage stamps, or a Postal Note. Do not send coins in any letter.

Fairs.—To any one exhibiting at Fairs, we will send samples of the BEE JOURNAL and a colored Poster, to aid in getting up a club. The Premiums we offer will pay them for so doing. For a club of 8 subscribers to the Monthly BEE JOURNAL, or 4 Weekly, we will present Dzierzon's Rational Bee-Keeping, price \$2.00.

Sample Copies of the AMERICAN BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
Monday, 10 a. m., Sept. 24, 1883. }

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The demand for extracted honey is exceedingly dull; for comb honey, only fair; arrivals are plentiful. Stocks are large in the hands of corn merchants and others. Our own supply is larger than ever, and, for the present, we cannot compete with commission merchants. We may have to offer lower figures. Our prices so far were 7¢ 9c. for extracted, and 14¢ 16c. for comb honey on arrival.
BEESWAX—Arrivals of beeswax are good at 25¢ 28c., and the demand is fair.

CHAS. F. MUTH.

NEW YORK.

HONEY—White clover and basswood in 1 and 2 lb. sections, 18c. Dark and second quality, 14c.; extracted white clover in kegs and barrels, 11c.; dark, 8c.

BEESWAX—Prime yellow, 30¢ 31c.

H. K. & F. B. THURBER & Co.

CHICAGO.

HONEY—Comb honey has been bought with more freedom this week, and prices of last week have been fully sustained. The cool weather has started up the usual fall trade, and activity is the order of the hour. In selecting out the best consignments (with the exception of one round lot taken by merchants from Dakota Territory), our demand is chiefly local. Extracted honey has not been sought for to any extent, yet there is an improvement over last week in the amount sold. Comb honey, extra white 1 lb. sections, 18c.; comb honey, extra white 1 1/2 lb. sections, 15¢ 17c.

BEESWAX—Steady and quiet, at 25¢ 35c., as to color, etc.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—There is a moderate supply of comb and extracted of common quality, but offerings of extra choice comb are very light. The sales being effected are within rather unchanged figures. White to extra white comb, 16¢ 20c.; dark to good, 10¢ 13¢; extracted, choice to extra white, 7¢ 9¢ 13¢; dark and candied, 6¢ 7¢.

BEESWAX—Wholesale, 27¢ 28c.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Some little inquiry for choice comb, from grocers, at 14¢ 16c. in fancy packages, but little or no demand otherwise. Offerings are liberal of strained and extracted, and dull at 6¢ 7c. Old and dark comb nominally cheap.

BEESWAX—Was selling at 25¢ 26c.

W. T. ANDERSON & Co., 104 N. 3d Street.

CLEVELAND.

HONEY—Comes very slowly and sells as fast as it comes at 14¢ 16c. for best white in 1 lb. sections, and 17¢ 18c. for 2 lb. sections. Second quality is very slow. Extracted usually sells very slowly in our market; as yet, no extracted has been received.

BEESWAX—None in Market.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—We quote our market at 18¢ 20c. for 1 lb. white clover; 18¢ 19c. for 2 lb. white clover. Extracted is in good supply, and selling from 9¢ 10c.

BEESWAX—Our supply is gone; we have none to quote.

BLAKE & RIPLEY, 57 Chatham Street.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Trial Trip—25 Cents.

As the season for Fairs has arrived, and wishing to be able to reach several thousands of the old-fashioned beemen, and by the aid of the BEE JOURNAL to lift them up to higher ground, adopting newer methods and progressive ideas, we make the following very liberal offer: We will send the Weekly BEE JOURNAL three months on trial, for 25 cents. In order to pay for getting up Clubs, we will give a copy of Fisher's Grain Tables, or Scribner's Lumber and Log Book, to any one who will send us five trial subscriptions (with \$1.25); for a club of ten we will give a cloth copy of Bees and Honey; for a club of 15, a cloth copy of the 7th edition of Cook's Manual of the Apiary; for a club of 25, we will present both the Manual and Bees and Honey. If any one wants these Books for nothing, here is an excellent opportunity to get them for a little exertion.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Articles for publication must be written on a separate piece of paper from items of business.

FOR SALE—Very cheap, 23 colonies of BEES. 17 colonies in Simplicity hives, and 6 colonies in Champion hives. All in good order for winter.

T. W. THOMPSON, MT. VERNON, IND.

BINGHAM SMOKERS.

I can sell the above Smokers at MANUFACTURERS' PRICES, by mail or express, at wholesale or retail. All the latest improvements, including THE CONQUEROR, and THE DOCTOR.

Send for my 32-page Illustrated Catalogue of Bee-Keepers' Supplies of every description.

ALFRED H. NEWMAN, 923 W. Madison, CHICAGO, ILL.

Don't Fail to Read This!

Only One Impure Queen Out of 950 Sent Out this Year!

The Queen received from you is the finest one I ever saw. She is remarkably prolific, producing the large workers, each bearing the three bands of gold.

W. H. WESTON, London, Ont.

I have 3 or 4 bee books, but yours goes ahead of all the others. WM. FLICKINGER, Doylestown, O.

OLDEST BEE PAPER IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

VOL. XIX.

CHICAGO, ILL., OCTOBER 3, 1883.

No. 40.

THE AMERICAN BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Abuse is Not Argument.

Mr. Hamet, the publisher of *l'Apiculteur*, in Paris, is opposed to movable frame hives. Fifteen years ago he wrote that the main quality of such hives was to be pulled to pieces like a pack of puppets. The honey extractor was, to him, a useless toy. He has continued since to fight against every new idea or improvement, and when we were in Paris, he ridiculed every thing in progressive apiculture which we use in America.

Mr. Hamet asserts that foul brood is generated by the use of frame hives. Mr. Chas. Dadant, of Hamilton, Ill., who has for years been writing for the European bee papers, has taken the ground that foul brood was propagated by contagion.

Last spring Mr. Bertrand, editor of *D'Apiculteur*, published a lithograph of Mr. Dadant, and was censured by Mr. Hamet for so doing; at the same time Mr. D. was assailed in the most vindictive manner. In the *l'Apiculteur* for August, Mr. Hamet renews the attack, more ferocious than ever, without the least provocation or excuse.

We exceedingly regret to see that Mr. Hamet has seen fit to use malicious personal abuse instead of argument. He also asserts that Mr. Dadant has been published as a humbug and swindler in *Gleanings*, and calls him anything but a gentleman.

Mr. Root justly denies that he had ever thought of publishing Mr. Dadant as a swindler. To us who have known Mr. Dadant for 10 to 20 years as one of the most gentlemanly, honest and progressive apiarists of America, these

insults are very annoying and perfectly unjustifiable.

It is a very poor way for any one to resort to malignity instead of using argument, but the use of such is more detrimental to the calumniator, than to the person maligned.

We should have taken no notice of this, were it not that Mr. Hamet assails him as a representative American apiculturist, and of no reputation for honesty, at home or abroad. How much better it would be to

Let all our words be full of truth,
Let kindly feelings reign;
Do good to all, and let our smiles
Leave blessings in their train.

Mr. A. J. King, editor of the *Bee and Poultry Magazine*, is going on a trip to Cuba this month—we presume for the benefit of his health. The BEE JOURNAL wishes him a pleasant journey and a safe return.

Several frosts have already occurred in many parts of the country, killing some of the fall bloom, but in other parts, the bees are reported to be at work quite vigorously.

At the Fair just held in Madison, Ind., Mr. H. C. White carried off all the premiums except one (which was the second premium on display of honey, and was awarded to Mr. S. D. McIntyre). Mr. White displayed comb and extracted honey, bees, hives, extractors and supplies for the apiary. We congratulate him on his success.

Alsike Clover.—The *Indiana Farmer* says that Mr. Alonzo Tyner, near Greenfield, Ind., grew several acres the present season in the same field with red clover, and said that the bees worked on it incessantly, and it was in its prime after basswood was over. Upon later introducing the stock into the field, the Alsike clover was eaten to the ground before they would touch the red clover.

Honey at the Iowa State Fair.

The Iowa *Homestead* has the following item concerning the honey exhibit at the Fair:

The Bee Department was a very attractive feature of the great Fair. Rev. O. Clute, of Iowa City, and J. J. Kizer, of Polk county, who are among the most intelligent and successful bee-keepers of the West, drew great crowds of people around them during the entire Fair, as they patiently and cheerfully explained the interesting processes of bee-keeping and honey producing. No feature of the Fair attracted more attention or awakened more interest.

The total value of the exhibits in the bee department of the Michigan State Fair was placed at \$1,088.50, and the amount of the premiums awarded was \$189. The building devoted to bees and honey, at the recent Fair, was well filled with everything of interest to bee-keepers. The exhibition of "supplies" was large, and attracted considerable attention from many who were not interested in apiculture. The "Bee-Keepers' Hall" was specially built for the purpose, and was a great attraction.

We have just received from the publishers a copy of the *Album Writer's Friend*, containing nearly three hundred selections suitable for writing in Autograph Albums. Those of our readers who have been invited to inscribe their sentiments in a friend's Album, will find this little volume a valuable help. It contains 64 pages, and will be sent by mail, post paid, on receipt of 15 cents, by J. S. Ogilvie & Co., Publishers, No. 31 Rose Street, New York.

The next regular meeting of the Mahoning Valley Bee-Keepers' Association will be held at Newton Falls, O., on the first Saturday of November, 1883. L. CARSON, Pres.
E. W. TURNER, Sec.

North American Bee Convention.

REPORTS OF VICE-PRESIDENTS.

The first report was from Dr. Miller, of Illinois. The season in that State, he said, was unfavorable. Even when white clover came, the bees lacked energy to go out and gather honey. Those who had fed bees during the winter did very well. The flow of honey from clover closed up earlier than usual, and since then they had none. About three-quarters of a crop had been obtained.

Dr. J. P. H. Brown, of Augusta, Ga., gave a fairly favorable report. The last report of the Commissioner of Agriculture in this State showed a product of only 27 pounds per colony. The horsemint, on which they depended largely, yielded not a single drop of honey, so far as he knew. A succession of heavy frosts in April had killed the bloom. The honey in Georgia generally was of amber color, and, for some reason which he did not quite understand, it was a few shades lighter this year than usual.

Judge Andrews, of Texas, stated that in North Texas the crop was very light, not more than 10 pounds per colony, but the honey was of very superior quality. It was obtained chiefly from rattan and honey locust, which came into bloom early in May. During the horsemint season (that plant yielded little or nothing) there was the most intense excitement among the bees if the hives were opened, or any attempt made to take the honey. In middle Texas there had been on the whole a good flow—a finer crop he had never seen. In West Texas the country had been settled for only three or four years, and few bees were kept.

Mr. O. O. Poppleton reported for Iowa. The yield of white clover honey in that State was heavy, but since that, there had been nothing. This was the worst season for robbers he had ever known.

Mr. Hart, of Florida, gave a very interesting report of bee matters in his State. The yield was an average one, but was from rather different resources than usual. Some of the bees swarmed as early as the 16th of February. In March came a drought, and the honey flow ceased almost entirely. In May the bees began to gather from the palmetto, bay and mulberry, but the crop from the last-named was very small. The bees took in the coast counties, took large quantities from the black mangrove which grows along the shore, and the roots of which are covered at high water.

Prof. Cook, of Michigan, reported that so far as he could learn, Michigan had got only half a crop. About 50 or 60 pounds per colony would be a fair average, of which one-third was comb honey. The season in the early part of the year was very rainy and very cold, but notwithstanding this the bees were very busy.

Mr. Jones—Have you many Canadian thistles?

Prof. Cook—I am glad to say we have very few. There was a droughty

fall, and it seemed there could be no more honey, but still the bees worked hard, and now, even though the frost had come upon them, the honey continued to come in.

Mr. W. C. Pelham, of Kentucky, reported on behalf of his State. The yield, he said, was much above the average in the white clover region, but in the mountainous region of the State, it was rather above the average.

Mr. Porter, of Colorado, reported about an average yield, notwithstanding that the spring was unfavorable. About a hundred pounds to the colony would be about the figure. A letter was read from J. L. Peabody, of Colorado, reporting only half a crop. They had snow in June, and frost in July and August. The Rocky Mountain bee plant had come along well in the dry, sandy soil, and the bees got a good harvest from it.

Mr. C. F. Muth, of Ohio, reported fully an average crop, partly from the locust, but mainly from the white clover. About 130 pounds per colony would be an average. After clover was over, the bees produced no more, in fact, they lost stores. His own bees had not stores enough to winter on, but in the few bright days after the recent frost, they had resumed work. He was sorry to say that honey had been forced upon the market in Cincinnati. He had been offered the best clover honey at 8 cents, or 8½ cents a pound. He had advised the bee-keepers to hold their stocks until the prices got better.

Mr. McKnight, of Owen Sound, President of the Ontario Bee-Keepers' Association, was called upon to report for Ontario. He cordially welcomed the representatives from a distance. The Ontario Association had been in existence only three years. He explained the system used by the Association in securing statistics, which was, to send to members of the Association slips with questions regarding the mortality of bees, increase, crop, etc. This year 48 out of 84 members reported. These reports showed a total yield of 211,772 pounds, an average of 106 pounds per colony. The average yield for the three years was 66 pounds per colony. The season this year was a strange one, the spring was backward, but on the other hand, the fall continued three weeks longer, making up for that to some extent. The principal sources of supply were the white clover, basswood, and Canada thistles. Among advanced bee-keepers there was very little out-side wintering.

Mr. Vandervort, of Pennsylvania, said he always found it hard to get reports. When there was a bad season bee-keepers were too busy to report. The early spring was favorable, but later, the season was wet and prevented the bees from working. There was only a half crop of honey, but a fair average of increase.

James D. Long, of Granby, supplied the report from Quebec. There had been a yield of fully 100 pounds per colony.

Rev. W. F. Clarke reported for Manitoba. Before doing so, he desired, as perhaps the only one from

Canada who had been present at the foundation of the Association, to express the pleasure it gave him to welcome the delegates to Canadian soil. He had learned since leaving that a few colonies of bees had been kept in the old settlement of St. Boniface, but had not known anything of them while there. He had seen only one bee while there, a stray Italian who had come from California in a box of fruit. The old friend of the Association, Mr. Wallbridge, was now Chief Justice of Manitoba, and resident in Winnipeg. He had had several "conventions" with the Chief Justice, and in company with him had examined the flora of the country. He had never seen such a magnificent yield of white clover, and was sure the bees would do well on it. Chief Justice Wallbridge was strongly of opinion that the steadiness of the climate would be favorable to wintering bees, and he intended to enter upon the practical work of bee-keeping.

PRESIDENT'S ADDRESS.

At the request of President Jones, Mr. McKnight, of Owen Sound, President of the Ontario Association, read the President's address, as follows:

It affords me genuine pleasure to meet with you all in this our usual annual gathering—pleasure for more reasons than one. I am pleased to meet with our American friends, who have honored Canada, and honored Toronto by choosing this as the place of meeting of the National Association. True, it is a "National" Association, but the representation from Canada is usually so small, we had scarcely the right to expect, much less enjoy, the pleasure of having Canada chosen as the place of meeting. I am pleased, because our own Canadian Association has turned out in such force to welcome our American brethren.

I am also pleased and proud to have, what has always seemed to me one of the things I most desired, and I am sure I only speak the mind and express the feelings of all our Canadian brethren, when I say that they have long wished for a chance to welcome to Canada's shores the "Father of Bee-keepers," the great "Huber of America," our venerable friend and brother, Rev. L. L. Langstroth.

Last winter was an unusually severe one to bee-keepers, but it was severe (with few exceptions) only to those who did not take the proper precautions in preparing for winter, at least so it has been with Canadian bee-keepers. I venture the assertion that much more care will be taken this fall to prepare for the coming winter. The spring came upon us unusually cold and wet, and this state of affairs was prolonged until nearly the first of June. Had the season opened as the majority of seasons do, many colonies would have escaped and come through all safe, though then very weak, but the cold and backward season completed the work which the careless bee-keeper began, and these colonies became victims of "spring dwindle."

ling." When the season came upon us, the majority were not ready to reap the harvest. The flow at first was only sufficient to supply material for a genuine "swarming fever," and I opine that many allowed too great a number of swarms. Only last week I received a report from one bee-keeper who had one colony in the spring, but who has no less than 15—an increase of 14. While the other honey-bearing sources supplied a fair proportion of the flow, still, to Canadian thistles, Canadians are indebted for the great majority of the crop of 1883. Bokhara clover has also done well, and I am of the opinion that it will become one of the future staple honey plants of the country.

On the whole, our beloved pursuit is in a most prosperous and happy condition. During the past season giant strides have been made in apiculture, both in the improved method of manipulation, and in the advanced ideas with regard to placing the products of the hive in a pleasing and salable shape before the people.

We may ascribe the success and advancement so obtained, in part, to the able manner in which all the subjects which tend to this advancement are handled by able and energetic writers in the many journals which the public have the benefit of perusing at a small cost, and which are constantly disseminating useful knowledge on matters interesting to bee-keepers. Conventions, such as this, have much to do with its advancement, as it is at these meetings that we learn from each other what each one of us has been doing during the past year, and by thoroughly discussing the various thoughts and experiences which are advanced, we are enabled thereby to arrive at correct conclusions regarding many questions which have held doubtful prominence in our mind until substantiated by like experiences from others.

Honey shows are likewise a great item in giving apiculture a helping impetus. I feel that it is the duty of every bee-keeper to take his entire crop to these places, whether the prizes are large or not, and when once the bee-keepers make the "Honey Department" one of the leading attractions of the Fair, the Agricultural and other societies will not long lie dormant in the matter, but each will vie with the other in trying to see which will have the greatest attractions in our department.

I cannot close without mentioning the honored dead—of such men as Wagner, Quinby, Colvin, Grimm, and a host of others who have gone before us, and who have done so much for us. I must also refer regretfully to the death of one of our number in the person of Theodore Houck, who has since we last met together departed this life.

It will soon be the duty of this Association to select another of their number to fill the position which I have so poorly occupied during the past year, and I feel that they will have little difficulty in selecting some one who will do the honors of the

position much more efficiently than I have been able to perform them.

Before closing I must again thank our American friends for their presence in Canada. I feel that this session will prove one of exceeding benefit to us all in reaping a harvest rich in valuable information, and I trust that it may long be remembered as such.

WHO SHOULD KEEP BEES?

The following is the address of the Rev. W. F. Clarke on the above subject:

"Everybody," was once the current answer. I have given it myself before now. Ten years ago, in my prize poem on "The Honey Bee," I pictured

"Each household of an apiary possessed."

It was the general idea then, that in a proper condition of society, a beehive out-of-doors would be considered as much a part of a well-regulated domestic establishment as a sewing machine in-doors. But we have got bravely over that, and many other crude notions that prevailed, even among bee-keepers themselves, ten years ago, and the time has now fully come for insisting upon it that only those should keep bees who are properly qualified to do so. That same law of division of labor which forbids every man being his own shoemaker, tailor, or blacksmith, prohibits every man from being his own honey-producer. Among the numerous topics of present and practical interest in the realm of apiculture, this deserves a prominent place, and it is especially fitting that it should come up at a gathering like the present. Every one of our annual meetings is followed by less or more abortive attempts at bee-keeping on the part of some who have attended and become inoculated with a desire to keep bees. There is always considerable enthusiasm awakened at these meetings, and it would be discreditable to us if there were not. Enthusiasm is contagious, and it is no wonder that people who know nothing of bee-keeping catch the infection, and go away determined, hit or miss, to start an apiary. It is more often a miss than a hit, and thus we become undesignedly the means of seducing our fellow-beings into disappointment. As a preventive of this, or at any rate as a check upon it, there should be some words spoken in plain English on these occasions in reply to the question, "Who should keep bees."

There is another reason why it is as well to discuss this question here and now. It is about the only good opportunity we have of doing so. It is not a congenial topic for the bee journals, many of which are, more or less, mixed up with the supply business. Of course the more people who start bee-keeping, the greater will be the sale of supplies. We cannot blame those who are in this business for wanting to make all the money they honestly can at it. It is not the most remunerative business in the world, there are too many in it, and the competition is too keen for it to be

very lucrative. So it is natural those who are in it should want to sell as many hives and "bee fixins" as they can. It is not their interest, perhaps it is not their duty to discourage beginners. But we have met, not as supply dealers, or with any personal or selfish ends in view. This is a grand apicultural parliament convened in the interest of bee-culture, and it is a part of our duty to do what we can to obviate whatever tends on the whole to the injury of bee-keeping. All will agree that it is not desirable for people to undertake what is sure to end in failure. Those who start at bee-keeping and make a botch of it are very apt to decry the whole thing as a humbug, a delusion, and a snare. No doubt the interests of bee-keeping, as a whole, have suffered from the maledictions of sore-heads, who, if they had been wise, would have never touched a bee hive, except to throw it aside.

Bee-keeping may be justly regarded as having attained the status of a profession, or a business. In any correct view of it, it requires special natural qualifications, and a thorough education. The natural qualifications are not of much account without an education, obtained somehow or other, and the education is a downright impossibility without the natural qualifications.

I feel myself somewhat at a loss in giving a categorical answer to the question I have taken as a text. It reminds me of the discussions there used to be, and are still, as to what constitutes a call to the ministry? Volumes have been written on that subject, and I think it would be easy to write a volume on the question, "Who should keep bees?" without, perhaps, throwing much more light on the subject than has been done by some treatises on the other theme. Nevertheless there is such a thing as a call to the ministry, and there is also such a thing as a call to bee-keeping. Many have hit their heads against a pulpit in the mistaken idea that they have been called to be preachers, and just so many have blundered into bee-keeping, under the delusion that they had a call in that direction. Something will be gained if we can impress people with the conviction that it is not wise to follow mere impulse. There is less danger of their blundering if we can get them seriously to ponder the inquiry, "Am I cut out for a bee-keeper?"

In a general way it may be safely said that in order to succeed in this business or profession there must be an aptitude for it. What that is it may be difficult to state in detail, but I am fast coming to think that the true bee-keeper, like the true poet, is born, not made. The great Huber is an example in point. To use a theological phrase, he was predestinated to be a bee-keeper, and not even the loss of sight could prevent the fulfillment of his mission. His devoted wife and trusty man-servant were eyes to the blind apiarist, and with their help he took the foremost place among historical bee-keepers. A degree of that enthusiasm which in-

spired Huber must influence all who aspire to rank among his disciples. No man succeeds very much in any line of things which does not stir him with lively interest. But this alone is not enough. The true bee-keeper must have keen perceptions, and be at once of an observant and reflective turn of mind. He must be a modern Job for patience, and a modern Bruce for perseverance. No matter what his natural aptitudes may be, he will make serious mistakes at first, and needs to learn that, as Napoleon was wont to say, "He is not the best general who makes no mistakes, but he who repairs them as quickly and as thoroughly as possible." He must not be irascible, for in that quality the bees are more than a match for the most irascible of mortals. He must have perfect self-control, for if a man cannot control himself, he may rest assured that he cannot control the denizens of the bee-hive. He must be sanguine and hopeful, for he will see many dark days. His motto must be:—

"Never give up; it is wiser and better,
Always to hope than once to despair."

He must have a mind for details, and regard nothing as trivial that has to do with the welfare of a colony or an apiary. "Unconsidered trifles" have often led to important discoveries, and astonishing results, and the man who is naturally prone to be negligent of apparently little things must either conquer that habit or come to the conclusion that he is not adapted to shine as a bee-keeper.

Lastly, at the risk of being laughed at by certain apiarists who can take bees to bed with them and sleep undisturbed, I shall venture to specify, a certain indifference to stings, which is characteristic of a few of the human family. There is no denying the fact that some people are highly sensitive to the virus of the bee, while on others it has little or no effect. Some curious experiences have been had in this line, of which truly intelligent bee-keepers will take note. It has been a favorite idea with many that when you become accustomed to being stung by bees, you cease to mind it. I was of that opinion at one time myself. I had become hardened to the thing until I did not mind a bee-sting more than a pin-prick. But on a luckless day I got a sting from a furious Italian just on the middle tip of my upper lip, which resulted in several hours' intense agony and a week's sickness. Ever since then, a sting in any part of the body results in a renewal of those painful effects. The virus at once flies to the head, and causes the greatest distress. I am aware that in this speaking I issue my own death warrant, as a bee-keeper, but I am at the same time stating facts which "nobody can deny." I am precluded from keeping bees except on a small scale, as an amateur, from purely scientific interest, and with the use of precautions in the way of gloves and veil, such as thicker-skinned and more hardened bee-keepers despise. But I lay it down as a maxim that unfortunate people who are keenly sensitive to the

effects of stinging, had better give bee-keeping, as a business, "a good letting alone."

In addition to the natural aptitude which has been imperfectly sketched, an education in bee-keeping must be obtained. It matters little how this is done, provided it be thorough. Let no one rush into bee-keeping imperfectly equipped with knowledge on the subject. It is positively ridiculous to see how some people act in regard to this matter. They seem to suppose that they have only to get a few colonies of bees and they are completely set up in the business. Their next step is to invent a hive or some wonderful improvement that is to eclipse everything in the market. After a little spluttering and flourishing they give up in disgust what they ought never to have attempted.

It is no doubt possible for a tyro in bee-keeping to become self-educated in a sense. With the invaluable bee books and excellent bee journals that are available, the theory can easily be mastered. Then comes the practical part, and "aye, there's the rub." To manage bees with an eye to profit from honey production, is an attainment far beyond mere theory, however correct. I do not think this can be gained in any other way so quickly or so well as for the beginner to apprentice himself to some good practical bee-keeper, and happy is he who has the opportunity of so doing. I am inclined to believe that our best bee-keepers will have to start schools of apiculture, as indeed some have already done. It may be so arranged as to be an advantage to them as well as to their pupils. Besides these private schools, apiculture should be taught both in theory and practice in agricultural colleges. The Michigan Agricultural College has set a good example in this respect, which ought to be followed by every similar institution on the continent of North America. Bee-keeping has now reached such proportions that it ought not to be ignored at those educational establishments which are devoted to the development of rural industries. As a source of national revenue it takes rank with general farming, stock raising, dairying, and similar out-door pursuits. As a science, bee-keeping covers a large field of research, and as an art, requires instruction quite as extensive as some other rural industries. This meeting will only be acting in harmony with its design and legitimate functions in making a strong deliverance on this subject. Bee-keeping has quite long enough been left to chance and hazard. It becomes those who are familiar with its wants and possibilities to exalt it to a proper position beside other occupations, and to demand for it suitable educational facilities. What I have said is intended to be introductory to an earnest and thorough discussion of the whole matter, and if it secures this my object will be secured.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Northwestern Convention.

The Northwestern Bee-Keepers' Association will hold its fourth annual convention at Owsley's Hall, N. W. corner Roby and West Madison Sts., Chicago, Ill., on Wednesday and Thursday, October 17 and 18, 1883, commencing at 10 a. m. on Wednesday and holding five sessions.

The Rev. L. L. Langstroth (the father of American apiculture) has promised to be present, and many of the most prominent apiarists of the Northwest will be there and aid in the deliberations and discussions.

This meeting will be held during the last week of the Inter-State Industrial Exposition, and reduced railroad fares may be had on nearly all the railroads. A cordial invitation is extended to bee-keepers every where to attend this annual reunion.

Meals may be obtained at the Restaurant near the Hall at 25 cts. each.

Beds may be secured at the Gault House for \$1, or at other Hotels at regular rates.

THOS. G. NEWMAN, Sec.
C. C. MILLER, Pres.

The sixth annual meeting of the Northern Michigan Bee-Keepers' Association will be held at Stone's Opera Hall, Sheridan, Montcalm county, Mich., on Tuesday and Wednesday, Oct. 9 and 10, to open at 10 a. m. of the first day. Evening sessions will be held, which will be interesting. At our last meeting it was requested that all interested in apiculture attend, and all who would, and could, furnish for exhibition apiarian supplies in the way of hives, extractors, implements used in the apiary, honey, honey-producing plants, and anything that would be interesting to a bee-keeper. Ample arrangements have been made to entertain all who will come. Let us have a general turn out, and see what we can learn one of the other. It will be a dull scholar who cannot profit by such a gathering. Feel assured we shall have an interesting time.

GEO. W. STANTON, Pres.
O. R. GOODNO, Sec.

The Iowa Central Bee-Keepers' Association will hold its regular annual meeting on Friday, Nov. 2, 1883, at the Court House, in Winterset, Madison county, Iowa. All bee-keepers are cordially invited to attend, and let us have one of the best meetings we have ever held in the State.

J. E. PRYOR, Sec.
Arbor Hill, Iowa.

Please announce that the Iowa Central Association, will meet at Winterset, Iowa, Nov. 2, 1883.

Z. G. COOLEY, Sec. pro tem.

Bee Battles and Robbing.

Mr. A. Pettigrew gives the following on the above subject in the *London Journal of Horticulture*:

Thieving scouts and skirmishing parties are common in all apiaries, and hard-fought battles are occasionally seen there, and plunder is the object. Robbing bees are watchful and crafty in attempting to enter hives not their own, and experienced bee-masters know them by their conduct. In watching for an opportunity to enter hives unobserved, they fly differently from bees engaged at honest work, and may be seen "standing on wing" in front of and close to the doors of hives they wish to enter, and if their attempts to enter be not resisted and thwarted they speedily accomplish their aims and carry home the honey. As soon as they gain access to it they convey to their own community the idea that a hive has been entered and honey may be had. The way in which the intelligence is conveyed is beyond our knowledge; all we here notice is the fact. The thieves of London know what "a cracked shell" means (a house broken into), and bees know what is meant by a hive undefended; and with marvellous rapidity the unresisting bees lose all their treasures.

Fortunately robbers are generally prevented from entering hives on their first attempt to do so. It may safely be asserted that in every hundred attempts to enter hives for plunder, ninety-nine are failures. When hives are weak their doors are often not well guarded, and robbers enter, and sometimes the robbers kill the whole of the small force of defenders. Strong hives, during a glut of honey, are sometimes off their guard, and let their hives be invaded, and if the robber bees are permitted to go in and out without hindrance for a short time they, generally speaking, take all the honey. Successful robberies of strong hives are not common. The robbers are generally discovered before they have done much harm—before they have lost the smell of strangers and foreigners, and when the discovery is made the bees of the invaded hive muster in strength to resist the invasion and make a determined stand against it. As some of the robbers have tasted the honey and carried off some booty, they are determined to have more, and are difficult to beat back. In their efforts to enter, the attacking force seems to increase in numbers and energy, and while hundreds of them are hurled back and off the flight-boards, hundreds more take their places, and courageously and persistently continue the attempt to take the place by storm. A well-fought bee battle is most interesting. If the door of the hive be rather small, and the robbers successfully resisted for a while (none allowed to enter), they give up the contest and retreat.

When a hive is attacked by robbers all the bee master can do is to contract the door, and thus make it more easy for the bees to defend it. If he

sees the robbers are resisted and repelled, he may know that they are so far unsuccessful, and if he find that robbers have gained access to a hive and are engaged in carrying off its honey without resistance, he should know that it can be saved by removal only to a distance of a mile or two for a time. If the robbing bees belong to the same apiary as those that are being robbed, the suggested manoeuvre of Quinby may be tried. His plan is simply to exchange the positions of the hives by putting the robbers on the stand of the hive they steal from, and *vice versa*, and thus confound the robbers. My opinion is, that bees are too clever to be outwitted by this. Our plan is to remove one of the hives to a distance of one or two miles.

Honey and Bee Show at Hancock, Co., Indiana, Fair.

The *Indiana Farmer* gives the following report of the above:

As per previous notice the regular monthly meeting of the Hancock County Bee-Keepers' Society, in connection with brother bee-keepers from adjoining counties was turned into a regular fair for the benefit of all interested. There was a good display of all the appliances necessary to modern bee-culture, besides a good showing of the products of the apiary for the present season.

The President of the society, Mr. Alonzo Tyner, exhibited an extractor, hive, section boxes, frames of wired foundation fully drawn out, a nice lot of honey, both comb and extracted, also a jar of preserves made with honey, which were very fine.

Dr. S. S. Boots showed a hive, extracted honey, and vinegar made from honey.

J. W. Jones brought in one of the old style of hives, also a chaff hive made by W. T. Falkoner, of Jamestown, N. Y., and a sample of foundation from J. Van Dusen & Sons, of Sprout Brook, N. Y.

J. T. Coffin exhibited a fine lot of honey in several shapes best suited to the trade.

The best showing was made by Mr. N. D. Coffin, who had on exhibition honey, both comb and extracted, vinegar, wired foundation in the several stages of being drawn out, and all the necessary tools for use in the apiary, besides a complete selection of all the producing plants native to this part of the country.

Mr. Geo. Cole, of Shelby county, showed some very nice queens in cages.

The regular meeting of the county society was opened and closed in a very short time to give all present a chance to talk and examine into the merits and conveniences of the articles on exhibition. The meeting was a very enjoyable gathering of bee-keepers, and all seemed pleased at the result.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

The fall meeting of the New Jersey and Eastern Bee-Keepers' Association will be held in the city of New York, at the Cooper Union, on Wednesday, Nov. 7, 1883.

J. HASBROUCK, Sec.
Bound Brook, N. J.

The Bee-Keepers' Association of Central Illinois will hold its next meeting on Wednesday, Oct. 10, at 10 a. m., at 205 South Main street, city of Bloomington. All interested, in this and adjoining counties, are invited to attend.

J. L. WOLCOTT, Pres.
JAMES POINDEXTER, Sec.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
Monday, 10 a. m., Oct. 1, 1883. }

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The demand for extracted honey is exceedingly dull; for comb honey, only fair; arrivals are plentiful. Stocks are large in the hands of corn merchants and others. Our own supply is larger than ever, and, for the present, we cannot compete with commission merchants. We may have to offer lower figures. Our prices so far were 7¢ for extracted, and 14¢@16¢. for comb honey on arrival.

BEESWAX—Arrivals of beeswax are good at 25¢@26¢, and the demand is fair.

CHAS. F. MUTH.

NEW YORK.

HONEY—White clover and basswood in 1 and 2 lb. sections, 18¢. Dark and second quality, 14¢; extracted white clover in kegs and barrels, 11¢; dark, 8¢.

BEESWAX—Prime yellow, 30¢@31¢.
H. K. & F. B. THURBER & Co.

CHICAGO.

HONEY—Comb honey has sold freely for the past two weeks, and stocks are at present low. 1 lb. sections of white comb are bringing 18¢; 1½ to 2 lb. sections of same quality, 16¢@17¢; various sized sections of white comb, 15¢@16¢. Extracted honey is selling faster, and prices are ranging from 8¢@10 cts. per pound, according to body and flavor.

BEESWAX—Yellow, 32¢@33¢; dark, 25¢; medium, 30¢.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—There is a fair jobbing trade. Offerings are not large. Choice qualities command extreme figures. White to extra white comb, 18¢@20¢; dark to good, 10¢@13¢; extracted, choice, 10¢ to extra white, 8¢@9¢; dark and candied, 6¢@7¢.

BEESWAX—Wholesale, 27¢@28¢.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Quiet. Salable at appended figures, but generally held higher. Strained and extracted at 6¢@7¢; comb at 14¢.

BEESWAX—Ready salable at 26¢. for prime.
W. T. ANDERSON & Co., 104 N. 3d Street.

CLEVELAND.

HONEY—Comes very slowly and sells as fast as it comes at 18¢@19¢. for best white in 1 lb. sections, and 17¢@18¢. for 2 lb. sections. Second quality is very slow. Extracted usually sells very slowly in our market; as yet, no extracted has been received.

BEESWAX—None in Market.
A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—We quote our market at 18¢@20¢. for 1 lb. white clover; 18¢@19¢. for 2 lb. white clover. Extracted is in good supply, and selling from 9¢@10¢.

BEESWAX—Our supply is gone; we have none to quote.

BLAKE & RIPLEY, 57 Chatham Street.

The Development of the Standard Langstroth Hive and Frame.

L. L. LANGSTROTH.

This form of hive was the result of many experiments. In the spring of 1852, as early as the weather would allow the bees to be shaken from the combs of my bar hives, (18 $\frac{1}{2}$ x 18 $\frac{1}{2}$ and only 6 inches deep) uprights and bottoms were nailed to these bars, so that in a few minutes they became movable frame hives. In the latitude of Philadelphia, at least, I never knew good colonies to increase faster, if as fast, than in such shallow hives.*

Not to speak of hives 13x13, x13 whose cubic contents were about the same with the standard Langstroth, and of other discarded sizes, I made, in 1854, hives 12x12x36, with frames now called "Gallup frames." The surplus honey was taken in boxes or frames in the rear of the main breeding apartment. They had movable tops as well as movable sides. The side doors, being chamfered on their edges, in opposite directions, could always be easily opened, and being suspended like frames, by top bars upon the frame rabbets, the size of the hive could be changed at will. Two such hives were placed, Dizerzon fashion, side by side—with entrances in different directions—crosswise on these, two more were placed similarly, and the pile continued, in the same fashion, as high as could be conveniently reached for manipulation—the whole colony having a common movable roof. Although my judgment was against such an arrangement, I could not rest satisfied until I had given this system a fair trial, and proved, by actual experience, that the necessary manipulations were so tedious, as greatly to out-weigh the advantages promised by such a compact arrangement. However it may be with our German friends; with us, economy of time is of vastly more importance than economy of space. I, therefore, took down the stack, and used the hives as top as well as side openers, until I left New England. I also used frames even larger than the Quinby size, but found them objectionable, because of the weight of the combs when full of honey.

These facts are sufficient to show, that the standard Langstroth hive was not the result of mere theoretical notions, or of traditional prejudices, nor did it come, by what some would call, a chance "happy-go-lucky" hit. Born out of many experiences, it was deliberately adopted, with the knowledge that at that time the great majority of our best bee-keepers did

not approve of such "low flat things." So deep was my conviction that its shape was better than the approved forms, that I could not consent to recommend any other.†

Although the chief reasons for the shallow form have been often given, it may be well, in this connection, very briefly to repeat them. Those who wish to see the subject more fully discussed, are referred especially to the old volumes of the AMERICAN BEE JOURNAL, where they will find the merits and demerits of the standard Langstroth hive very thoroughly canvassed.‡

My tenacious adherence to the Langstroth form, led some to imagine, that perhaps in some way or other, the validity of my patent might depend on this shape. This reminds me of a once noted writer on bees, who while warning persons against infringing upon his patent (although he had never taken out any patent), closes thus: "Even an external imitation of my hive will not be suffered to pass with impunity!"

The broad and low shape which I introduced, in addition to giving the much-desired top surface for surplus honey receptacles, has the following advantages:

1. It is obviously much better adapted to the use of upper stories, than taller hives. It seems more natural to bees to place their stores over their central brood-nest, than any where else. When extracting unsealed honey, I kept neither honey board nor any thing else over the tops of the frames to interfere with handling the frames, as soon as the roof over them was removed. A glance at the tops of the frames was enough, with Italian bees, to show if extracting was needed, for they would begin to extend their comb-building upwards, even if they had plenty of room for this work on empty side frames. Now, why should bees attempt the difficult work of upward comb building, against the law of gravity, by which their suspended combs are kept in a perpendicular position, while they have ample side room for building them in the natural way? Why, I say, do they act thus, unless it is most in accordance with their instincts to place their stores above their brood-nest?

If honey, to have its choicest flavor, ought not to be extracted—as the Dadants and other of our leading apiarians assert||—before it has been

† In latitudes where bees can be either safely wintered in the open air, or in proper in-door depositories, a still shallower form of hive may, perhaps, be found preferable.

‡ Of all editors whom I ever known Mr. Samuel Wagner was the most judicial. In his attitude on all matters pertaining to bee-culture. Fair play was to him a precious jewel indeed.

|| Use the word apiarian both as adjective and substantive, without the authority of Webster or Worcester, because it sounds much better than apiculturist, and is repeatedly so used by Dr. Edward Heaen in his work on the honey-bee—than whom there is no writer on bee-culture who is higher authority among English-speaking people.

capped, and if when all bee-work is most pressing, more colonies can be taken care of by piling hive upon hive, filled with empty combs—to be emptied when more leisure comes—then the advantages of shallow hives are easy to be seen.

2. If we do not make the number of frames so small, that to get the requisite comb surface, they must be too heavy for easy handling, then for cheapness and other obvious reasons, the fewer frames the better. For this reason, if there were no others, frames of the Gallup size seem to me objectionable.

3. Long and shallow frames are more convenient for most of our necessary manipulations.

(a.) In handling them the arms take a natural and easy, instead of a cramped position.

(b.) With such frames the eye commands the whole surface of a comb, in searching for the queen, etc., without that uncomfortable craning of the neck which deep frames compel.

(c.) As has been already explained, there is less danger of hurting bees in removing or replacing the shallow frames.

(d.) Less motion, and of course less time, is needed to take out or put back such frames.

(e.) It is very much easier to make such frames hang true, than deep ones. If their hives had glass on their backs, many who use deep frames would be surprised to see how much "out of true" they often are.

Whatever may be the case with bee-keepers, in a small way only, those who are manipulating for hours together, in large apiaries, and to whom in the press of work, time saved means more money, than in any other season of the year, will find the above reasons for giving the preference to the long and shallow frame, worthy of careful consideration. They are submitted, however, in no spirit of dogmatism, and I am far from claiming that the standard Langstroth is demonstrably the best under all conditions, and for all parts of our widely extended country. The time will probably never come, when uniformity will be as much insisted on as in the standard weights and measures of the same country. If by a simple volition, I could, without pecuniary loss to any one, or violence to any one's feelings or prejudices, change every movable comb hive in America, into the standard Langstroth size, I would will no such change. Let the Dadants, Hetheringtons, and others, have full scope for testing on the largest scale their different forms, only let there be, as far as possible, uniformity in each style, so that any purchaser will know precisely what size, under a given name of hive, he is getting. I am sure that Mr. Root, and others, will be willing, when requested, to make hives of the standard Langstroth size—and if Mr. Root will call his size of frame the *Simplicity Langstroth frame*, there will in the future be plain sailing, at least before all who use the shallow Langstroth frame.

Oxford, Ohio, September, 1883.

* Bingham, Marvin and others prefer hives about six inches deep.

Read at the Maine State Convention.

How to Make Bee-Keeping Profitable

ISAAC HUTCHINGS.

To make bee-keeping profitable we should keep the best strains of Italian bees in preference to the black or German bees. Some of the new races of bees may prove equal or superior to the Italians, but they have not been sufficiently tested to warrant a change. The dollar queen traffic, if rightly managed, will be a blessing to the intelligent apiarists, as it will open a market for the small and inferior queens that might otherwise find their way into the class of tested queens. I believe that bees winter better and build up quicker in the spring where they are well packed with chaff or dry sawdust on their summer stands, than they do when wintered in a cellar. Spring dwindling, I believe in most cases, is a result of cellar wintering. Those who winter in a cellar use a single-walled hive, and when they put them out in the spring the sun will warm them so that many will fly out when the air is so cold that they become chilled and never return. If we have a few days of warm weather, and they have all the brood that they can care for, one cold night will drive the bees into a cluster and leave the brood to die. The bee hive needs protection from the rays of the sun, and the cold storms and winds of early spring, as much as it does in the winter months when there is no brood to chill. We should encourage breeding early in the spring, remembering that it is the early bees that store the surplus honey.

The old box hive is a thing of the past with all progressive bee-keepers. A movable comb hive is indispensable to profitable bee-keeping. As soon as the weather will admit in the spring, we should examine each colony so that we may know if they are in need of any of our aid. No. 1 may have lost their queen; No. 2 may be short of stores; No. 3 may be weak in numbers and need a frame of ripe brood. It would be very difficult to ascertain the wants of a colony in a box hive without movable comb frames. I should be very sorry to have a colony die for want of food or care after they had survived our cold winter.

If our bees are well wintered and well cared for in the spring, they will be ready to divide or swarm before the white clover honey harvest. If we divide it should be done at least ten days before the honey flow commences, and the honey sections should be put on soon after, so that the bees may get settled down to business in season to give us good returns. In dividing, leave each colony as strong as it will do, and not induce swarming.

Comb honey should be put up in neat and attractive packages, and we should not destroy the market by forcing too early sales. Some sold their honey for 20 cents per pound last August, and if they kept it until October it would have sold quick for

25 cents per pound. To make bee-keeping profitable we must have a love for the business, and if we do not love the business end of the bee, we should learn not to fear it. We must become acquainted with the natural laws governing the honey bees. A "Manual of the Apiary" will be found in the library of every progressive bee-keeper. We have made great improvements in bee-culture within the last decade, and many more are needed and are continually being made, and unless we subscribe for and read a good live bee journal, we shall be left behind. I frequently find a single article in my bee journal that is worth more to me than the price of a year's subscription.

Nothing is better calculated to mislead us than the idea that bee-culture has acquired perfection, and that we know it all. It is true that Americans lead the world in this art, but it is in its infancy, and who can tell what the coming bee will be like? We should keep a register of the apiary, so that at a mere glance we can ascertain the age, race, strain and quality of the queen of any colony, determine the character of her progeny, the amount of honey stored and the increase. By having a history of each colony before us, we can avoid many mistakes that will occur, if we depend upon a treacherous memory. We should have everything needed in the apiary on hand and ready for use at the commencement of the season, and we should give our bees all needful care, and supply their wants at the proper time. There should be no putting off until to-morrow what should be done to-day.

For the American Bee Journal.

Freaks of Queens, Observed by Me.

ROBERT CORBETT.

I would like to mention, through the BEE JOURNAL, the freaks of queens that have come under my observation.

In July, 1882, I opened a hive to introduce a queen in the old way, in a wire cage on the face of the comb; in the operation she got away, and flew out of my sight. Three days later I opened the hive to put in another, and there, to my surprise, I found my queen at her daily work, depositing eggs as majestically as if she had been there for months.

A swarm came out of a hive on the 18th inst., that I had re-queened last August; the queen was very prolific, keeping the hive well filled with brood; ten days after hiving, I opened the hive to see how she prospered, and to my astonishment not an egg was to be seen; now, how is this, I would ask, that she is not laying, if the old queen leads the swarm?

Fifteen days ago I had some nucleus hives, with virgin queens, for fertilization, and when about 5 or 6 days old, we had 2 or 3 very windy days, from the 25th to the 28th; at the cessation of the wind, I examined my

nuclei, and found I had lost 2, and on the first of September I had a hive (No. 22) that threw out a swarm; 3 or 4 days later I examined hive No. 22, to take out the queen-cells and give it a laying queen. Frame after frame was lifted out, and there was not a queen-cell nor the appearance of one in the hive, but a nice yellow queen was there; how is this, did not one of my lost queens find her way in there, and, being protected by workers, therefore forced a swarm? that is all the way that I can account for it.

On Friday of last week, I was called upon to help Mr. E. Kimble to extract some honey, with the assistance of Mr. Solomon Whitney, and during the operation of manipulation, in one colony that had swarmed a week previous, several queen-cells appeared, as the queen left them, but one that was not open, being larger than usual, our curiosity led us to open, and what did we find, but two queens in one cell; one was quite as large as usual, while the other was not quite so large, but of fair size; other cells being hatched first, the bees had pierced this one, therefore they were dead; is that not something new to the bee men of the age?

Manhattan, Kansas, Sept. 10, 1883.

For the American Bee Journal.

Michigan State Fair, Bee and Honey Show.

W. Z. HUTCHINSON.

The interesting, magnificent, unapproachable Bee and Honey Show of the Michigan State Fair, which closed yesterday, was a brilliant success in the highest sense of the word. Such a large and interesting show has never before been made at a State Fair, and one gentleman who has visited the bee and honey shows of Europe, pronounced it finer and larger than those of the old country.

Very much of the success of the show is due to Mr. H. D. Cutting, who has labored for years to have the Agricultural Society recognize bee-keeping as an industry, and at last it has been recognized—the officers are very much interested, and will do almost anything in reason that we may ask of them.

To go on and describe, in detail, all the exhibits, would take too much space, hence I will speak in a general way.

H. D. Cutting, of Clinton, Mich., showed the largest exhibit of implements and bee-keeping literature. He had over 60 varieties of implements, and 50 specimen copies of periodicals and publications.

E. T. Lewis & Co., Toledo, Ohio, exhibited implements, and received first premiums on honey extractors and wax extractor. They also exhibited a mammoth smoker, 2 feet in height. There was a whistle in its mouth, and an organ at the back of the bellows, and was warranted to play six tunes. The instructions on the back were: "Take me out to see your hybrids." Many was the laugh raised by this smoker.

James Fry, Leslie, Mich., made a display of fancy cases filled with comb honey, one colony of bees, and a pyramid of wax.

August Koeppen, Flint, Mich., had on exhibition a mammoth extractor capable of receiving six combs, or, if only three combs were used, an automatic arrangement can be brought into requisition, and the combs turned by a simple touch of the finger. He also had a hive, the walls and bottom board of which were stuffed with tow.

C. M. Weed, of the Agricultural College, Lansing, Mich., made a magnificent display of honey-producing plants pressed and mounted. There were more than 50 varieties, and so well was the work done that the natural colors were entirely preserved.

W. O. Burk, Crystal, Mich., had on exhibition a complicated hive called the "queen home winter protector," and, strange as it may seem, it received the first premium.

The exhibit that had the most "shine" and "show" and glitter was that made by M. H. Hunt, Belle Branch, Mich. This exhibit occupied one-fourth of the building, and consisted of hives, extractors, comb foundation machine, and other apiarian implements. His honey was put up in almost every conceivable shape, in glass jars, glass pails, glass bottles, tin pails, tin cans, all labeled with showy labels, and arranged in rows and piled in pyramids; one pyramid, arranged upon a large stand of circular shelves, was especially fine. The comb was built in fancy sections of wood, glass and mica; some with openings in the centre for placing bouquets. His three pyramids of wax were molded in very fancy shapes, and surmounted with flowers. He also had 2 colonies of bees out-of-doors.

Your humble servant (W. Z. Hutchinson) also occupied one-fourth of the building, and made the largest and finest display of comb honey, which was piled up in the shape of a pyramid until it actually reached the roof. The base of the pyramid was 20 feet. He also received the first premiums on the specimen of 10 pounds or more of comb honey; this specimen being arranged under a glass case, which was lettered in gilt letters, "Gilt Edge Honey." He also exhibited 3 colonies of bees in an observatory hive, so arranged that visitors could place their noses right against the glass, and this part of the exhibit was surrounded by a crowd from morning till night. His pyramid of wax was surmounted by an old-fashioned straw hive formed of wax. It received the first premium. His exhibit of pressed honey-producing plants were bound in an Emerson binder, and placed where the crowd could examine it, and I guess he will have to make a new collection. He received premiums to the amount of about \$80. Mr. Hunt's premiums "figured up" to somewhere between \$50 and \$60; Mr. Cutting's to \$33; other exhibitors received from \$2 to \$8.

The city papers gave up excellent notices, and spoke of it as a "new

and novel feature." The Governor gave us a call, and was introduced to the exhibitors. The public said, "Why, this is the most interesting thing I have seen."

Rogersville, Mich., Sept. 23, 1883.

Grange Bulletin.

Beeswax and its Production.

J. M. HICKS.

Wax is a vegetable product deriving its origin from the saccharine principles existing abundantly in the products of nature. It is found upon the surface of the leaves of many trees in the form of varnish, and possessing all the qualities of beeswax. The wax bearing myrtle (*Myrtus Ceriferi*) a shrub which grows abundantly in Louisiana and other parts of the United States, produces wax in large quantities; and there are also in many parts of the East and West India Islands shrubs that produce wax in great abundance. The myrtle bears a small berry, of which wax forms its outer coating, and when exposed to a flame burns with an agreeable aromatic odor.

Dr. Darwin supposes that the design of the waxen varnish which covers the flowers is "to glaze over the fecundating dust of the anthers and prevent its premature explosion from excess of moisture, and ascribes to an unseasonable diffusion of anther dust, the failure of orchard and corn crops in summers of extreme humidity. The quantity of wax found in this form is small compared with that which is produced by the honey bee, and also of inferior quality. When pure it is of a whitish color and destitute of taste, with scarcely any smell; it grows brown and even black with age. After manipulation it has an aromatic smell, which, however, disappears on exposure to the atmosphere. The dust of flowers, called pollen or farina, was long supposed to be the element of wax, and it is a curious instance of the tardy progress of the knowledge of natural history, that though the mode in which wax is produced by the bees was ascertained beyond all doubt by Huber over 60 years ago, this fact is yet but little known, and farina continues to have the credit of being what is called "crude wax." Buffon was of this opinion, and, in an edition of his work published as late as 1821, no notice is taken of the recent discoveries on the subject, which prove his opinions to be erroneous. Reaumur was inclined to believe that pollen, by receiving some peculiar elaboration from the bees, was converted, in the stomach, to real wax, and disgorged under the appearance of paste. Later observers, however, denied that wax was disgorged by the mouth; they affirmed that it exuded from the rings of the abdomen in the form of small scales, and that pollen was used for very different purposes. That this last mentioned substance is not the prime constituent of wax, was a conclusion drawn by repeated and accurate observations by our most celebrated apiarists.

It has been observed, for instance, that pollen is carried into the hives in great abundance, that were already filled with comb; that it is often of various shades, while new combs are always of pure white; that new swarms for a few days carry in no pollen, although their first work to be done after being hived, is the building of new combs, which progresses with unremitting rapidity; and while it has been stated that 100 pounds of pollen have been carried into a hive during one season, the whole weight of the comb in the hive, when separated from the honey and farina, weighs something less than 2 pounds.

Huber lodged a young swarm in a straw hive, furnished them with honey and water, and after five days confinement he perceived that they had consumed the whole of their provisions, and had constructed several combs of beautiful wax. These combs were removed and more honey given them, and the result was the same. This removal was made five times successfully, and on each occasion being supplied exclusively with honey, they produced new comb, thus putting it beyond dispute that this substance effected the secretion of wax in the body of the bee.

And, further, to ascertain whether the saccharine principle was the real source of wax, he supplied the captive bees with sugar in the form of syrup, and the result was still the same, wax was produced, and that in a shorter and in greater abundance than from honey, as the reverse of this experiment would prove whether pollen had the same property, instead of supplying the bees with honey or sugar, he fed them only on fruit or farina. They were kept captives eight days under a glass bell, with comb having only farina in the cells; yet they neither made wax nor were there any scales of wax on their abdomen, as was the case when honey and sugar were used.

It is but justice to the Scotch bee master, Bonner, to remark that amidst the errors that prevailed on this subject during his day, he had a strong impression of the real source of wax and the manner of its secretion. In this, as in other parts of bee science, his natural acuteness and shrewdness of observation led him to the very verge of some of the most important of those facts in the natural history of bees which we owe to the more scientific researches of Huber. "I have sometimes," says he, "been inclined to think that wax might be an excrement exudation, or production from the abdomen of the bee, and that the queen can lay eggs whenever she pleases; so, if required, the worker bees can produce wax from the substance of their own bodies."

If this conjecture be right, it will follow of course that all the food which a bee takes contributes to the formation of wax in the same manner as all the food a cow eats contributes to the nourishment of her body and the production of milk; (bees consume much more honey or sugar

when wax is required,) or to adopt a nearer simile from the insect tribe, as all the food a spider takes contributes not only to the nourishment of the animal, but to the production of the substance of the web from its body.

Numberless other analogies in nature might be cited in proof of the probability of this theory. The silk, for instance, produced from the body of the silkworm, is a substance as different from that of the animal itself, or the mulberry leaf it feeds upon, as wax is from that of the body of the bee, or of the honey or flower she sucks. And the exudations in the human ear which goes by the name of wax, is certainly as different from the substance of the body which produces it, as either the one or the other.

Upon the whole, until we meet with a more probable theory supported by facts, we must give it as our humble opinion that wax is produced only in one way, and in all cases upon the abdomen of the bee in very minute scales, and that wax cannot be produced unless the bee feeds upon honey or sugar, or what honey and sugar is produced from, and that bees do not produce wax continually, but only at such times as comb is needed in the storing up of honey. At such times bees consume a much greater amount of food than when there is no need of comb.

We here desire to give the analysis of beeswax, but time and space will not permit, trusting as we do, that some of our readers at least will become more or less interested in the science of apiculture, and still extend their research by procuring more elaborate works on the subject, and in this way which, if possible, become more interested in this, one of the most beautiful sciences.

For the American Bee Journal.

Wintering—the Pollen Theory.

DR. G. L. TINKER.

Evidently, Mr. Heddon, judging from his reply to my article, does not have a very clear idea of what the "humidity theory" is. Mr. S. Cornell, on page 728 of the BEE JOURNAL of 1882, gave the first well-defined views on this subject, and to this article Mr. H. is respectfully referred. Other articles on the subject will be found in the present volume on pages 7, 165 and 199.

Heat is a very important element in the successful wintering of bees, and it is one, moreover, that my generous opponent has apparently lost sight of completely. He gives several examples that are grimly supposed to annihilate the humidity theory. The first is, where bees have been taken from cellars, "drenched with dampness" but in good health. In the same connection, Mr. Balch is quoted as saying "that all upward ventilation was death, that dampness was good for bees, and that he wintered with great success." All of which may be true, and yet fully accounted for by the humidity theory. For it seems

that it does not matter how damp the hive may be, or the air outside, if there is good ventilation, and the conditions are such that the *normal heat of the cluster* can be maintained, no harm can arise from the presence of dampness or moldy combs. Mr. Cornell, nor myself, would undertake to contend that dampness is injurious to a colony of bees except under conditions in which the heat of the cluster could not be maintained, owing to the presence of unusual cold and dampness. The theory is "that cold and dampness are the primary causes of bee dysentery." Mr. Balch named conditions that would tend strongly to retain the heat of the colony, a vital point upon which he was justly very emphatic. And again, his bees had undoubtedly good lower ventilation.

But Mr. H. finds a "misfit" for the theory in the fact that he lost 48 colonies all in a few weeks after placing them in a very "dry cellar." And yet he would undertake to dismount me if I should get on his bacteria hobby (that is, if there should be found "any strength" in it), and claim it as his own! I am not sure but Mr. H. has got this double hobby horse for a sly purpose—if one gets lame he can "get on to other," and when that one gets lame he can get back again! Verily, if there was a show for his bacteria hobby any where, it would be in just such a case as the losing of 48 colonies all within a few weeks after going into winter quarters. But the humidity theory will account for the loss, if there was insufficient ventilation. I fear that there are yet many bee-keepers who are still undecided that bees need a great amount of winter ventilation.

O no, Mr. H., do not think that any one will try to get the honor of fathering the pollen theory away from you. You have a sure thing on that. But I am at a great loss to understand how "the bacteria theory is much the same thing." I can readily understand how a circus performer can ride two horses at once, but did not know before that we had a bee-keeper who could perform this interesting equestrian feat. Your logic on this point is too profound for me.

Now it was just possible that I was "mistaken" in regard to those hybrids. All hybrids have queer habits. They may have got up some dark night, walked out, evacuated, and returned without my knowing it. Certainly, Mr. H., but I was not mistaken in regard to my way of adjusting sections. It is true that I have delayed my report on the use of small sections so long that it is not surprising that you should have thought my experiments a failure. I promised to make the idea advanced last winter a success, and it is accomplished quite beyond my expectations. In this place, I will simply thank Mr. H. for his derisive allusion to "the man who sets his sections down on the brood frames" with the suggestion that he has stumbled upon a boomerang that will recoil soon enough.

I am glad to learn that Mr. Heddon will test the pollen theory on a large

scale the coming winter. He will find, however, that no little narrow bive like his, can be made to winter bees successfully on the summer stand without more "fixing" than can ever be made to pay. Not only this, but his hive has not enough surface on the top, nor enough space in the cases, as illustrated a year ago, for safe wintering. The surplus department of a hive on the summer stand in winter should contain not less than 4,000 cubic inches of space. I am, therefore, not surprised that Mr. Heddon has poor success in wintering. He would succeed better with the standard Langstroth hive.

In conclusion, I would like to ask by what slip of the pen Mr. H. came to predict that "disease will get me before old age." Of course, that must be a "mistake," or else, "In wondering mazes last," my friend has turned Prophet!

New Philadelphia, Ohio.

Penobscot County, Me., Convention.

The Penobscot County, Me., Bee-Keepers' Association met according to adjournment at Burrell Hall, Corinna, Sept. 6, at 10 a. m., with President Judkins in the chair. There was a fair attendance of members.

After the usual business of the association was attended to, the subject of the relations which the county associations should hold to the State associations was brought up, and all were united that some action should be taken by the State Association to bring us all into working order, as one society, and the following resolution was offered and accepted:

Resolved, That the Maine Bee-Keepers' Association needs, and should have the support of every county association in the State; and that the Penobscot County Bee-Keepers' Association extend to it, its most loyal support.

The afternoon session was opened by a spirited discussion of the following questions: 1. How to control swarming; 2. Is it advisable to clip queens' wings; 3. How to feed in the spring, is it advisable? 4. How to make bees swarm; 5. The different races of bees, their qualities compared; 6. The best method of Italianizing; 7. The best method of wintering, the proper temperature for cellars. These and other questions kept the time well occupied until night, and a good interest was shown. The general opinion was that the day had been well spent. Thirteen members signed the roll book, showing that old Penobscot has not forgotten that she has had the honor of instituting the first bee-keepers' association in the State—the Maine Bee-Keepers' Association being formed there—and that she means to be ahead as a county association. The next meeting will be held at East Corinth, Thursday, Nov. 1, at 10 a. m.—*Home Farm*.

Articles for publication must be written on a separate piece of paper from items of business.

For the American Bee Journal.

The Northwestern Convention.

JAMES HEDDON.

Some way or other I have got the idea into my head that the above named convention is going to lead all other bee associations in the world. Why? First, because, as Mr. Clarke so ably puts it, "it is conceded that this continent now leads the world in apicultural progress;" secondly, no where is this "progress" on such swift-winged pinions as in the West. Especially is this true of that portion of the West easily accessible to that great centre of commerce and science, —Chicago.

The rates during this meeting are about one-third the usual, on nearly all railroads. No equally good meeting can be gotten up with so little effort and cost as a Northwestern. Father Langstroth is to be at our next Oct. 17 and 18 meeting. Let us greet the faces of hundreds of the "get there" honey-producers of the country, from East, West, North and South, and let us see if we cannot all go away feeling and knowing that we have not only had a good time, made the acquaintance of the veteran Huber of apiculture, but we have learned points regarding this calling that will many times pay us for the cost and trouble of the attendance, and leave us the fun and frolic more clear gain.

I imagine I hear the response now echoing all over the country, "Yes, we'll be dar, suah as your boun."

Dowagiac, Mich., Sept. 27, 1883.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Uniting Colonies of Bees.

Will Mr. Heddon please give his method of uniting bees, in the Weekly BEE JOURNAL? W. V. WEBSTER.

Quaker City, O., Sept. 12, 1883.

ANSWER.—If I have colonies to unite, I pick out such combs and such number of them as I wish to put the newly-made colony on, for winter, and then shake the bees all into a box together; then empty them in front of the hive, and let them all run in together, removing all but my choice in the queens, and caging her between the combs, as in any case of introducing, and liberate her in the same way. I very seldom have any fighting, and if you wish to prevent that, you might take the extra precaution of sprinkling the bees with slightly-sweetened water, scented a little with peppermint, or some other pleasant odor. Put in but little of the scent, and do not let outside bees get a taste of your

sweetened liquid, and thus induce robbing. If the colonies united stood some distance apart, you might set the newly-formed colony in a cellar for a few days, and then lean a board in front of the entrance when you set them out to fly, just before sun set. Of course, tact is needed to get the minutia of the work done, so as to be perfectly adapted to the surrounding conditions.

SELECTIONS FROM OUR LETTER BOX

The Fall Crop of Honey.

The bee-keepers have been somewhat encouraged for a better collection of winter stores than it promised the morning of the frost. The weather has been warm and pleasant most of the time, and our pets have worked pretty well. The frost did not seem to hurt fall bloom very much, so we still hope we will not have much fall feeding to do; this we will all know, if we will examine when the honey flow is over. I met the vice-president of the Michigan State Society yesterday, in Marshalltown. I find him good in a talk about bees. We would like to have some good men at our next meeting, Oct. 6; if any of them are out this way, or even feel like coming on purpose; we are expecting a good turn out, for many have expressed a desire to be there then. The bee-keepers' interest is growing very fast in this part of our State. The demand for honey, both comb and extracted, is on its increase. Our people are getting afraid of glucose adulterations.

J. A. W. SANDERS.
Le Grand, Iowa, Sept. 27, 1883.

A Good Paying Crop of Honey.

The weather is very cool and extremely dry. We have had scarcely any rain since June 15. Our bees have plenty of honey, but no brood; in fact, less brood than I ever saw at this time of the year. The goldenrod is in full bloom, but yields no honey; but why should a Kentuckian complain, after such a clover harvest as we have had? Besides, experience teaches us that the weekly visits of the good old AMERICAN BEE JOURNAL will brighten the prospects, and give new vigor to those who have to record "blasted hopes." I commenced the season with 75 colonies; and have increased to 130, mostly by natural swarming. I have taken 7,600 pounds of choice honey, of which 400 pounds were in the comb; the balance was extracted. I have sold, in our home market, the extracted honey, at 12½ cents per pound; and the comb honey at 16½ cents. Early in the season I sold 12 barrels of extracted honey at 10 cents per pound. The demand for honey is good; and I have sold all I have taken, and know that bee-keeping pays.

JOHN T. CONNLEY.
Napoleon, Ky., Sept. 26, 1883.

Worker Bees in Queen-Cells.

On page 433 of the BEE JOURNAL, A. Rickenbacher mentions a "Curious Freak of Bees," and Mr. Heddon's answer is: "I have never had a case like the one above referred to. I do not know as we have any precedent of the kind." I am quite surprised that Mr. Heddon and others have not noticed that workers very often get sealed up in old queen-cells. I have known for several years, that workers very often crawl into the queen-cells after the queens hatch, and sometimes get sealed up. A little observation on the part of apiarists during the following season, will reveal the fact that more than one worker in 50 hives will get sealed up in queen-cells.

R. S. BECKTELL.
Three Oaks, Mich.

White Cake Made with Honey.

DEAR EDITOR.—As requested I send you the recipe for the cake made with honey on which I took the first prize at the Tri-State Fair at Toledo, last month:

One-half teacup of butter, three cups of flour, one-and-a-half cups of honey, one-half cup of sweet milk, one-half teaspoonful of soda, one of cream of tartar, and the whites of three eggs.

Delaware, O. MAY BESSE.

Frost Killed All the Flowers.

The honey crop in this part of the country is almost an entire failure. Since the middle of July the bees have hardly held their own; I fear the late swarms will have to be fed, to give them enough stores to winter on. Last night we had a frost that wiped out all the flowers, so that this year will foot up rather short.

H. J. SCOLES.
Knoxville, Iowa, Sept. 26, 1883.

The "Scarlet Wing" Story.

I am quite astonished to read in No. 36, of the BEE JOURNAL, a ridiculous story from a correspondent about my having a queen with four hands and scarlet wings. Although I hardly believe that any intelligent apiarist has believed it, I wish you would publish my formal denial.

H. SONTAG.

Cucamonga, Cal., Sept. 13, 1883.

Parched Ground in Louisiana.

We have had no rain for about one month and a half, until to-day when we had a good one. The bees were really discouraged at the drough. There was hardly any honey secreted, the soil split and left the roots of many plants bare to the heat of the scorching sun, which ended their honey secreting. Snake root, golden-rod, smart-weed and boneset are opening fast, and the bees are booming with full force to get all of the nectar they can.

G. E. SONNEMANN.

New Iberia, La., Sept. 16, 1883.

Intelligent Work.

Bees have done passably well here this season, though it has been very dry, except in August. My 14 colonies increased to 32, and I have about 600 pounds of comb honey, which I am selling at 18 cents per pound. This is a large per cent. over my neighbors, and is the result of reading the BEE JOURNAL and the use of comb foundation. I hope it will long continue its weekly visits, and directed by its present editor, that its mission may be a successful one.

B. H. HOLT.

Adel, Iowa, Sept. 19, 1883.

6,000 lbs. of Honey from 30 Colonies.

I have now 70 colonies of bees; increased from 30 in the spring; have taken 6,000 pounds of honey, mostly extracted, and of an excellent quality; it is all basswood and clover honey. I wintered my bees, last winter, in an out-door cellar, built for the purpose, and lost none in wintering, but lost 4 by spring dwindling. My bees were in the cellar nearly 5 months. I have Italian bees, and think them far better, in every respect, than the native bees.

A. C. SANFORD.

Ono, Wis., Sept. 10, 1883.

The Cass County Bee-Keepers' Association, organized on the 15th of August, will meet on the 10th of October, 1883, in Logansport, Ind. All persons interested in bees and honey are respectfully invited to come.

DE WITT BROWN, Sec.

The quarterly meeting of the Marshall County Bee-Keepers' Association, will be held at the Court House, in Marshalltown, Iowa, on Saturday, Oct. 6, at 10.30 A. M. Subject for discussion, "Fall and Winter Care." All interested, in this and adjoining counties, are invited, for we hope to have a good meeting, and one of benefit to all.

J. W. SANDERS, Sec., LeGrand, Iowa.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00, or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper, shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter, on your label, notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a statement of account every week.

Trial Trip—25 Cents.

As the season for Fairs has arrived, and wishing to be able to reach several thousands of the old-fashioned bee-men, and by the aid of the BEE JOURNAL to lift them up to higher ground, adopting newer methods and progressive ideas, we make the following very liberal offer: We will send the Weekly BEE JOURNAL till Dec. 31, *on trial, for 25 cents.* In order to pay for getting up Clubs, we will give a copy of Fisher's Grain Tables, or Scribner's Lumber and Log Book, to any one who will send us five trial subscriptions (with \$1.25); for a club of *ten* we will give a cloth copy of Bees and Honey; for a club of 15, a cloth copy of the 7th edition of Cook's Manual of the Apiary; for a club of 25, we will present both the Manual and Bees and Honey. If any one wants these Books for nothing, here is an excellent opportunity to get them for a little exertion.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
" 100 colonies (220 pages)..... 1 50
" 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey at Fairs, will sell almost a fabulous quantity of it.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Books at Fairs.—Those who make an exhibit at Fairs will find that an assortment of Books and Pamphlets would sell and leave them a profit for handling. We will send such, postage prepaid, at 25 per cent. discount; or if the purchaser pays express charges, we will supply any of our own publications at 40 per cent. discount.

The new two cent rate of postage for letters went into effect on October 1. Three cent postage stamps will now be but little used. For all fractions of a dollar sent to us hereafter we should prefer either one-cent, or else five or ten-cent postage stamps, or a Postal Note. Do not send coins in any letter.

T. B. Peterson & Brothers, 306 Chestnut St., Philadelphia, Pa., publish this day, "THE BRIDE OF LAMMERMOOR," being the second volume of their new and cheap edition of "THE WAVERLEY NOVELS," BY SIR WALTER SCOTT, which will be completed in Twenty-six Weekly Volumes, each volume being a novel complete in itself, and the volume will be issued every Saturday until the whole are published. Each book will make a large octavo volume, uniform with "Ivanhoe," and "The Bride of Lammermoor," have on it an Illustrated Cover, and will be sold at the low price of Fifteen Cents a volume, or Three Dollars will pay for the full and complete set of Twenty-six volumes, and copies of any of the novels, or complete sets of the edition will be sent to any one, post-paid, at these rates.

SECTIONS.

We have just put in several new machines and also a larger engine in our factory, consequently we are in better shape to fill orders than ever for Sections, Shipping Crates, etc., etc. We make a specialty of our

"BOSS" ONE-PIECE SECTIONS,

Patented June 28th, 1881.

We can make the "Boss" One-Piece Sections any size or width desired. Send for Price List.

We make the Half-Pound Section any size desired.

CHICAGO, ILL., OCTOBER 10 1883.

No. 41.

THE AMERICAN
BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Next week the annual re-union of bee-keepers will be held in Chicago. The present indications are that it will be most interesting and largest gathering ever held in the Northwest. Many of the prominent apiarists in this region have already indicated their intention of being present, and we think that no one who can possibly attend, should be absent. The Rev. L. L. Langstroth writes us that his health and energy is a surprise to himself as well as his friends, and he fully intends to be present. The invitation is cordial and universal—**COME.**

Mr. M. L. Trester, Secretary of the Nebraska State Association, has sent out blanks to be filled up by the bee-keepers of that State, giving the statistics necessary to the proper estimate of the honey crop in that State. This is commendable, and should be followed by similar efforts in all the States. Will the secretaries please take the hint?

The trial between exhibitors making comb foundation at the Tri-State Fair, was quite an attraction. We met Messrs. Vandervort and Pelham for the first time, and were well pleased with them and their machines. The Given press also did excellent work, and was admired by all who saw it. Dr. Besse had a good exhibit of honey and supplies, and added largely to the interest of the show. E. T. Lewis & Co.'s exhibit was large and varied, and the faithful services of Mr. Puhl, in showing the different articles to visitors, made it very attractive to bee men.

Honey Harvest in Scotland.

From a letter just received from Mr. J. D. Hutchison, of Glasgow, Scotland, we glean the following concerning the honey harvest of that country. There, as well as in America, the early frosts and cold and wet weater have ruined the fall crop of honey. Mr. H. says:

From the accounts which have been received from various parts of Scotland, it appears that the honey harvest is to be an almost entire failure. Owing to the late spring, bees had to be fed to prevent their starving. Although they bred well and swarmed numerously, the wet and cold weather that prevailed during almost the whole summer hindered the storing of honey. After a bad summer there is generally the prospect that in autumn the heather will aid in making up the deficiency, but this year, unfortunately, this hope will not be realized, as the heather yields little or nothing.

Bee industry is now becoming more generally cultivated, and in average years is highly productive. The weather has been very broken for sometime past, so the most of bee-keepers have taken home their bees from the heather, and are preparing them for the ensuing winter.

Concerning the bee and honey exhibits at the St. Louis Fair, Messrs. Flanagan & Ilinski, of Belleville, Ill., writes as follows:

The show of bees and honey at the St. Louis Fair was superior to that of last year, being much more extensive and in better order, and more exhibitors taking part. Wm. Little, of Marissa, Ill., had 1st and 2d premium (\$20) for the best display of Italian bees. Mr. E. Armstrong, of Jerseyville, Ill., obtained 1st premium on the best crate of honey, and his display certainly deserved it. Your humble servants got the 1st premium for the best display of apiarian implements. Three years ago not one hive or bee or crate of honey were exhibited, but this year there was a display that was attractive to all visitors to the Fair. Your "Honey as Food and Medicine" went like hot-cakes. The management have our thanks for the privilege of selling honey during the Fair; a privilege not accorded heretofore.

The New Postal Laws.

As many are in doubt about the new regulations of the Post Office Department, and to save trouble to our subscribers, we will recapitulate them:

The postage on letters is 2 cents for each half-ounce or fraction thereof.

The old two and three-cent stamps now in use will continue valid, and must be accepted in payment of postage whenever offered in appropriate amounts.

Postage to foreign countries remain unchanged, with the exception of Canada. A letter goes to Canada for two-cents; but Canadians have to pay three-cents for a letter to the United States as formerly.

The drop-letter rate of postage remains the same—that is, two-cents per half-ounce or fraction thereof, at free-delivery offices, and one-cent at all other offices; and no changes are made in the rates of postage on second, third and fourth-class matter.

An item has been going the rounds of the papers, to the effect that a late order of the Postmaster General provides that no package, parcel or letter will be forwarded upon which the postage has not been fully paid. This is erroneous, as no such an order has been issued. Letters weighing over one-half ounce, on which one full rate has been paid, will be forwarded, and the balance collected on delivery. If a letter contains a one or two-cent stamp, or no stamp at all, it will be returned to the sender if he is known, and otherwise the person to whom it is addressed will be notified, and upon receipt of the postage the letter will be forwarded.

Mr. A. Benedict had at the Tri-State Fair an observatory hive with some of the most beautiful bees we ever saw—well marked and of a uniform and large size—the result of 20 years of careful breeding.

Treatment and Cure of Foul Brood.

The London *Journal of Horticulture* contains the following on the above subject:

A correspondent, some time ago, sought information on this subject. So far as I know no more valuable hints and instructions have appeared than in the columns of the *Journal*, and especially I would direct attention to what has been written by Messrs. Cheshire and Cowan. From these writings I will cite. Mr. Cheshire observes—"When foul brood breaks out it attacks grubs only, and for a fortnight or so no actual difference is effected, but as it spreads population is reduced from two causes: Young bees do not all hatch out, some die prematurely, and the odor generally diffusing itself takes all heart and energy out of the workers; the brood-nest gets by degrees choked, and the laying energy of the queen is thus repressed. The general effect is the gradual weakening of the colony it is true, but all can see that time is required for the destroyer to accomplish his purpose, and despite his sad work making havoc within, the bees may appear to be in the full swing of unhindered progress until the disease has a firm hold of every comb.

"The curability of foul brood is the next point upon which I wish to insist. While we feel sure that the doctor can do us no good, we will not take his medicine, and while bee-keepers believe that foul brood must run its course and work out devastation and ruin nothing will be done to arrest it. I assert its curability because I have again and again cured it, and in this position I am pleased to be able to refer to one of the most prominent, certainly one of the most scientific and successful apiarists of our day—T. W. Cowan, Esq., chairman of the committee of the British Bee-Keepers' Association, whose experience in the treatment of this malady has been great, but not greater than it has been successful. Mr. Cowan, in reply to a request that he would permit a publication of his methods, has favored me with a lengthened letter, in which he says, 'I am quite, I think, of your opinion as regards foul brood, that is to be cured if attacked in earnest. You know I had it in my apiary, and it was a source of great trouble to me, but I stamped it out with salicylic acid. My proceeding was to excise any very bad places, and when I found cells affected here and there I merely uncapped them and sprayed the combs with the solution of which I send you the recipe. I found generally in mild cases one application was sufficient, but in more severe ones two or three doses produced a complete cure. I found that if the cells were uncapped before they were punctured and sprayed with the solution, injecting a larger quantity into the affected cell so as to eject the viscid mass, there was no fear of the disease appearing again. In this state the viscid fluid in the cell is of a light brown, and is not permeated with spores to such an

extent as when it is allowed to remain until it becomes highly colored, and the covering much depressed. I doubt very much if in this stage it is very contagious. I have no doubt the acid acts on the spores and destroys their vitality. So far so good. Now as regards the honey that is in the hive, and which is supposed to contain the spores (although I must say I have never been able to detect any by the microscope), how are we to insure their being destroyed? Simply by uncapping it and feeding the bees on syrup containing the acid, which they will store with the uncapped honey, or uncap it and give it a good spraying with the acid solution. I have done both, but cannot say if it was really required; but as I think prevention is better than cure, and as it is not much trouble, there can be no harm done.

"All my hives are scalded, and so is everything that has had anything to do with the hive, and afterwards everything is washed over with the solution. I believe the germs of the disease are carried in the air, and we can feel safe; I, therefore, always put acid in all the food I prepare. I examined six of my hives, and all were healthy but one, and that I thought was also healthy. It was an early swarm. This year I had thrown off a swarm and a cast, and had given me six small one-pound sections nicely filled. I looked on the ten frames and found no queen and no brood. There was one cell covered, but not punctured, but I at once recognized as a foul-broody one. Now the hive had not been queenless very long, as about ten days ago I saw the queen; and, although, she was not laying, there was a small quantity of brood hatching out, and all did hatch out except this one cell; it was uncapped and injected with the solution, and the other combs and bees sprayed with it. I have no doubt it will prevent its spreading in the future, as I shall not hesitate in using these combs in uniting if I require them.

"I have examined six hives to-day, fearing to find foul brood, but have not detected a single cell in any of the other hives. Now, how did this appear? It seems to me probable that it was brought there by some of the bees from outside, or a spore might have been lurking in some of the corners of the hive and had escaped the solution. This proves to me that it is impossible to tell when it may break out in an apiary; and as we know from experience that salicylic acid destroys the spores, I think it not only beneficial but important that a certain quantity of this acid should be in all the food given to the bees. Two years ago I tried feeding the bees on syrup containing a strong dose of acid without spraying the combs, and I found that the disease gave way to this treatment; but I find the other plan, that of uncapping and spraying, the most rapid. I do not mean to say if a hive is neglected, so that all the brood is rotten, it can be cured; but if taken in time, as every apiarist would do, it has been and can be cured. THOS. WM. COWAN.

The table of recipes Mr. Cowan encloses will explain themselves.

Salicylic acid solution for mixing with syrup for feeding bees, painting over hives, and spraying combs, etc., for the prevention of foul brood.

Water.....	4 pints.
Salicylic acid.....	1 oz.
Soda borax.....	1 oz.

Spring and summer food for bees:—

White lump sugar.....	10 lbs.
Water.....	7 pints.
Vinegar.....	1 oz.
Salicylic acid solution.....	1 oz.
Salt.....	½ oz.

Boil for a few minutes.

Autumn and winter food for bees:—

White lump sugar.....	10 lbs.
Water.....	5 pints.
Vinegar.....	1 oz.
Salicylic acid solution.....	1 oz.
Salt.....	½ oz.

Boil for a few minutes.

Northwestern Convention.

The Northwestern Bee-Keepers' Association will hold its fourth annual convention at Owsley's Hall, N. W. corner Roby and West Madison Sts., Chicago, Ill., on Wednesday and Thursday, October 17 and 18, 1883, commencing at 10 a. m. on Wednesday and holding five sessions.

The Rev. L. L. Langstroth (the father of American apiculture) has promised to be present, and many of the most prominent apiarists of the Northwest will be there and aid in the deliberations and discussions.

This meeting will be held during the last week of the Inter-State Industrial Exposition, and reduced railroad fares may be had on nearly all the railroads. A cordial invitation is extended to bee-keepers every where to attend this annual reunion.

Meals may be obtained at the Restaurant near the Hall at 25 cts. each.

Beds may be secured at the Gault House for \$1, or at other Hotels at regular rates.

THOS. G. NEWMAN, Sec.

C. C. MILLER, Pres.

"Take me out to see your hybrids." was the label on a mammoth smoker exhibited at the Tri-State Fair by Messrs. E. T. Lewis & Co., Toledo, Ohio. It was about 2 feet high, and proportionate otherwise, with a whistle and an organ, to make music as operated. It caused many an audible smile among the bee men who examined it.

Please announce that the Iowa Central Association, will meet at Winterset, Iowa, Nov. 2, 1883.

Z. G. COOLEY, Sec. pro tem.

Bees in a Religious Meeting.

A correspondent of *Farmers' Home Journal*, in the following letter, tells how a congregation was warmed and sinners made active, lately, in Kentucky, by a swarm of bees:

"You may have read the story of Sut. Lovingood's dad in a hornet's nest, but that affair was not a circumstance to what took place at the Methodist church in Lafayette, Ky., on last Sunday. Your correspondent was not present, and feels glad that he was not, but has the facts from a reliable gentleman who experienced the quickening power from the business end of a bee, which he thinks would rival the eloquence of Beecher or Spurgeon in stirring up a sleepy congregation.

"Rev. J. W. Bigham, the good pastor and eloquent preacher, occupied the pulpit. Whether or not he needed any assistance in warming up his congregation, as preachers like to do, just before conference meeting, he got it, in the form of a swarm of angry bees. The atmosphere seemed alive with the insects. They poured into the house by wholesale, precipitating a revival. Sleeping members were aroused from their slumbers to a shouting pitch, before the preacher reached the point in his sermon where the shouting should come in, and the sermon was cut short. The spirit (or rather the bee) soon pervaded the entire congregation, and the ladies also were quickened to a sense of the awakening, losing all care for their bangs and curls. Never did worshippers assume a more humble attitude. All who could, crawled under the pews, while those made excessively warm by an inspiring touch from the sweet singers, continued in the more lively exercise. Real solid joy, however, did not take possession of the congregation until the doors and windows were all closed, and the regular battle of bee-killing was over. The bees were finally stopped out of the house, when they commenced on the horses and men out doors. A number of horses broke loose and ran away. Mr. John W. Davidson had a fine buggy torn to pieces by his horse trying to escape from the bees. A pair of fine bay horses, belonging to Mr. Ed. Moses, standing to the breast yoke with loose traces, and hitched with very strong halters, were literally stung to death; one of the horses died on the spot in less than two hours. Several horses were stung so badly that they could not move from the place when cut loose. Messrs. John Covington, Ed. Moses and others were badly stung in trying to rescue their horses.

"Brother Bigham closed the services by announcing that there would be a meeting next Sunday at the usual hour, provided the bees should settle. The ladies, however, had to remain in, with closed doors, until a bolt of musquito goods was procured for veils. One lady concluded she could run the blockade—she was not afraid of bees any way; but she had

never come in contact with a swarm of missionary bees, and never knew how beautifully she could perform, until she met these red-hot ministers.

The National Convention.

Mr. C. F. Muth has sent us the names of the members attending the North American Bee-Keepers' Society at Toronto last month. They are as follows, and 101 in number:

CANADA.—W. F. Clarke, F. Malcomb, Rev. F. Allen, S. T. Pettitt, John Myers, S. C. McNeil, James D. Long, S. Corneil, R. McKnight, R. Harper, Mr. and Mrs. Robert H. Myers, J. B. Hall, J. E. Schantz, John Baxter, Mrs. Wm. Bryce, Rev. Wm. Blain, A. G. Willows, H. A. Russell, W. Ellis, A. Crichton, H. Dobson, C. D. Corbin, A. D. Allen, S. Wood, O. Snyder, A. Grove, E. Muillholland, A. Douglas, G. B. Jones, W. H. Morrison, I. P. Blakeley, W. Nixon, H. Lipsett, Rev. J. R. Black, J. Anderson, Mr. and Mrs. S. G. Holly, W. C. Wells, Wm. Buglass, A. E. Gilpin, Chas. T. B. Jones, W. G. Russells, Mrs. W. G. Russells, Miss Edith Russells, Jacob Spence, Mrs. Jacob Spence. In all, 47.

NEW YORK.—W. E. Clark, D. Baker, J. C. Newman, T. Pierce, G. W. House, J. E. Stanley, G. W. Stanley, R. Baker, D. A. Parmeston, Mr. and Mrs. E. B. Ross, W. V. Bosworth, Jr., B. F. Gates, W. H. S. Grout, H. S. Elkins, F. L. Smith, W. T. Falconer, L. Whitford, C. Humphrey, M. L. Spencer, S. L. Sleeper, L. Corey, E. C. Hubbard, J. H. Umpleby, Mr. and Mrs. W. L. Coggsall, W. E. Moulton, Ira C. Nicholi, Mr. and Mrs. C. Favill. In all, 30.

OHIO.—C. F. Muth, A. I. Root, G. W. Freeman, F. Whiteside, Dr. H. Besse, Miss May Besse. In all, 6.

MICHIGAN.—Prof. A. J. Cook, Dr. C. E. Rulison, R. S. Taylor, Wm. Moorhouse, W. Harmer. In all, 5.

TEXAS.—Judge Andrews.

KENTUCKY.—W. C. Pelham.

GEORGIA.—Dr. and Mrs. J. P. Hill. Brown.

COLORADO.—W. L. Porter.

FLORIDA.—W. S. Hart.

MASSACHUSETTS.—S. M. Locke.

NORTH CAROLINA.—G. E. Boggs.

IOWA.—Mr. and Mrs. O. O. Poppleton.

ILLINOIS.—Dr. C. C. Miller.

PENNSYLVANIA.—C. J. Haight, J. McGonnell.

The life members, having paid \$10 each for such membership, are D. A. Jones and Thos. G. Newman.

There are several honorary members of the Society, and among them the Rev. L. L. Langstroth. The names of the others may be gleaned from former reports.

In 1880-81, the list of members contained 105 names.

Articles for publication must be written on a separate piece of paper from items of business.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL,
Monday, 10 a. m., Oct. 8, 1883.

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—Our prices are 7@9c. for extracted, and 14@16c. for comb honey on arrival.

BEESWAX—Arrivals of beeswax are good at 25@28c., and the demand is fair. CHAS. F. MUTH.

NEW YORK.

HONEY—White clover and basswood in 1 and 2 lb. sections, 17@21c. Dark and second quality, 14@15c.; extracted white clover in kegs and barrels, 9@10c.; dark, 8c.

BEESWAX—Prime yellow, 27@29c. H. K. & F. B. THURBER & Co.

CHICAGO.

HONEY—Comb honey has sold freely for the past two weeks, and stocks are at present low. 1 lb. sections of white comb are bringing 18c.; 1½ lb. sections of same quality, 18@17c.; various sized sections of white comb, 15@16c. Extracted honey from 8@10 cts. per pound, according to body and flavor.

BEESWAX—Yellow, 32@33c.; dark, 25c.; medium, 30c. R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—There is a fair jobbing trade. Offerings are not large. Choice qualities command extreme figures. White to extra white comb, 16@20c.; dark to good, 10@13½c.; Extracted, choice to extra white, 8@9½c.; dark and candied, 6½@7½c.

BEESWAX—Wholesale, 27@28c. STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Quiet. Salable at appended figures, but generally held higher. Strained and extracted at 6½@7c.; comb at 14c.

BEESWAX—Ready salable at 25@26c. for prime. W. T. ANDERSON & Co., 104 N. 3d Street.

CLEVELAND.

HONEY—Comes very slowly and sells as fast as it comes at 18@19c. for best white in 1 lb. sections, and 17@18c. for 2 lb. sections. Second quality is very slow. Extracted usually sells very slowly in our market.

BEESWAX—None in Market. A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—We quote our market at 18@20c. for 1 lb. white clover; 18@20c. for 2 lb. white clover. Extracted, 8@10c.

BEESWAX—We have none to quote. BLAKE & RIPLEY, 57 Chatham Street.

KANSAS CITY, MO.

HONEY—A large part of the local crop in this section has been marketed, though considerable remains yet in the hands of producers. Very little California honey in this market this season, except extracted, which is in fair supply at 19@21c. for choice new, and 8½@9c. for dark or candied. Choice bright comb 2 lb. sections, 18@19c.; 1 lb. sections, 19@20c. Demand is fair for the better grades.

JEROME TWICHELL, 536 Delaware Street.

The next regular meeting of the Mahoning Valley Bee-Keepers' Association will be held at Newton Falls, O., on the first Saturday of November, 1883. L. CARSON, Pres. E. W. TURNER, Sec.

The Bee-Keepers' Association of Central Illinois will hold its next meeting on Wednesday, Oct. 10, at 10 a. m., at 205 South Main street, city of Bloomington. All interested, in this and adjoining counties, are invited to attend.

J. L. WOLCOTT, Pres. JAMES POUNDENTER, Sec.

CORRESPONDENCE

For the American Bee Journal.

The New Races of Bees.

G. M. DOOLITTLE.

About a year ago I gave my opinion regarding the Cyprian and Syrian bees, stating that I should not have anything more to do with the Cyprian on account of its vindictive disposition, and although not favorably impressed with the Syrian, I should give them a more thorough trial during the season of 1883. To this end I procured queens of the Syrian or Holy Land race of three different breeders during the fall of 1882, so I could have full colonies of those bees in time for the honey harvest.

The result of this season's work with them proved the same as that of 1882, which is, that for this locality the Holy Land bees are practically good for nothing as honey gatherers. With a locality where there was a steady flow of honey the case might be different, but here we get little or no honey until basswood, and these bees seem to think that a large flow of honey should mean lots of brood, so at brood-rearing they go, the result of which is, nearly all the honey they gather is used up rearing an extraordinary amount of brood, which hatch so late in the season that the bees from said brood are too late to gather honey, hence become consumers of the little honey already in the hive. Therefore, when fall arrives, we have a hive overflowing with bees, with little or no honey, and scarcely a pound of surplus to recompense the owner. All are aware of my views regarding the secret of honey-producing, lying in, getting the bees just in the right time for the honey harvest (neither too early or too late), that being of more moment than any one other thing pertaining to honey producing.

That the Syrian bees cannot be thus managed in this locality is the reason of my saying they are practically good for nothing. Then they have another exceedingly bad feature, which is, that before the young queens are fertilized in the present hive, which has cast a swarm, fertile workers spring up, and the result is a queenless colony, unless great pains are taken to introduce a laying queen. This, with me, as I allow natural swarming, would be a very serious drawback, but might be got along with if they were enough better honey-gatherers to warrant an extra outlay of time in looking after the young queens. However, as in all respects, unless it is in wintering, they are inferior to the Italians. I felt warranted in doing away with them entirely, and to-day finds my yard without a Holy Land bee in it.

After deciding a year ago that I would have nothing more to do with the Cyprians, I thought, perhaps, I had been a little hasty, as I had up to this time but one queen of that race

in my yard. As a whole, I was pleased with them, except their great disposition to sting whenever the hive was opened. When spring opened I found that my Cyprian colony had wintered the best of any colony I had except the old Holy Land colony, and hearing so many favorable reports of the Cyprians, I concluded to give them a further trial. Consequently I procured a queen of B. F. Carroll and E. T. Flanagan, as they seemed to prefer them to any other bees. These, with my old one, made 3 colonies, and as far as getting the bees in the field in time for the harvest, I am well pleased with them; as in fact I am with all other points about them except the "stinging point."

If I could call the queen I had from Mr. Flanagan pure, I should think there was some prospect of getting peaceable Cyprians, but she evidently is not pure, for her queen progeny is of a mixed multitude, being all the way from jet black to as golden yellow as I ever saw an Italian queen, while the daughters of the Carroll queen, and from my old colony, are nearly duplicates of the mother. The bees from the Carroll queen are the worst to sting of any bees I ever saw, and I thought the original colony was bad enough. Mr. Carroll says, in a late number of the BEE JOURNAL, that he has Cyprian bees which he can handle without smoke, veil or gloves, but he does not tell us whether he considers them pure or not; neither does he tell us how many colonies he has of the stamp produced by the queen I got of him.

Now, Mr. C., in all candor, and desiring information, I ask how you manage such bees as the queen you sent me produces. That you knew they would sting is proven by your saying when you sent her, that if she proved too "trey," I could send her back. Perhaps I may do so in the spring, when even the Cyprians can be handled quite comfortably, but I would not open that hive to-day to get that queen for all the queens of like stamp there is in the world.

Mr. T. S. Bull, a large bee-keeper of Valparaiso, Ind., called on me not long ago, and I told him of these bees. As he wished to see them, I took off the cover to the hive and raised the quilt a little, smoking them all the while, but for all that a cloud of angry bees rose in the air, crawling into our pockets, under veils, and where ever they could get, all the time singing such a sweet tune, like an angry bee can when he gets in your hair. They seem to care nothing for smoke, and how any one can manage them for extracted honey, is more than I can understand. I worked them for comb honey, and to say that I was glad when I had the sections off that hive does not half express it. In shaking the sections to rid them of bees, nearly all the bees would take wing and come for me like so many angry hornets; and, although I care little for stings, I confess that my flesh fairly crawled at the sound of a quart or more of angry bees hissing about my bee-veil, and occasionally stinging through pants and shirt.

Now, if any one can tell how I can manage these Cyprian bees from the time the honey harvest commences until winter, I shall be glad to keep a part of Cyprians in my apiary, but if they cannot, I shall have to bid them adieu, for their stinging qualities more than over-balance all their good traits.

Borodino, N. Y.

For the American Bee Journal.

Winter Ventilation and Protection.

DR. G. L. TINKER.

The experience of bee-keepers appears to be widely different on the proper size of the entrance of a hive in out-door wintering. One will tell you to make it not larger than $\frac{3}{8}$ by 4 inches; another $\frac{3}{8}$ by 8 inches; and still others recommend $\frac{3}{8}$ by the width of the hive inside. My own recommendation for a full colony is to make the entrance $\frac{3}{4}$ by 8 inches.

To keep out mice, set the hive on a stand made as follows: Make a box 4 inches deep, just the size of the bottom of the hive, out of heavy boards 4 inches wide. If the side boards are 5 inches wide, the bottom can be nailed inside into rabbets made in the lower edge of the front and rear pieces. The stand looks better if the bottom is nailed inside. Lastly, nail four pieces 3 inches wide by a foot long to the front and rear corners. These pieces should be planed smooth, and all ought to be painted. Now set the stand on four bricks let into the soil on a level, and till quite full of dry sawdust. Sit on the hive and move about until it fits firmly. There is very little danger from mice to a colony on such a stand, and besides, it is far more convenient for the bee-keeper. No sawdust or other material need be put around the hive to keep down weeds, for the weeds will grow anyway, unless the sawdust is often removed. The scythe is the best thing to keep down the weeds and grass. The stand also keeps the hive up from the ground, so that there is less danger from dampness. Again, a lot of hives set on these stands presents a very neat appearance. Heretofore I have had my hives set near the ground upon bricks, and I find that there are many disadvantages in having them set so low down.

My reason for so large an entrance is, that bees require a large amount of fresh air in winter, and the most natural point for the air to reach them is through the entrance. There is nothing more certain than that a very small entrance, $\frac{3}{8}$ by 4 inches, is too small for the bees either in winter or summer. The proper size of entrance for a strong colony in summer, according to my mind, is $\frac{3}{4}$ by 13 inches. When the bees are breeding in the spring, and the nights are cool, then the entrance should be small, but at no other time of the year.

With a large entrance, there should be a very small amount of upward ventilation allowed, and that through not less than 7 inches of chaff gently pressed down. Some fine chaff like

timothy is the best. It is thought that the cracks where the cover fits to the hive will let out sufficient air, unless very tight, but no large openings should be allowed in the cover. If put in loosely, the wet chaff on the surface, over the cluster, can be replaced with dry, three or four times during the winter; otherwise it will be liable to get moldy and create a bad odor. I do not, on this account, recommend a chaff cushion over the bees, because it would become quite foul before spring, unless more air was allowed to pass in and out of the cover than would be advisable. The point is, to allow no more upward ventilation than is necessary to permit the dampness coming from the bees to arise to the surface of the chaff. I should say, that if the chaff over the cluster was, after a time, found dry, that the ventilation through the cover was too free. For, in my opinion, the only benefit to be derived from upward ventilation is in allowing the dampness to pass upward at the same time that the heat of the bees is effectually retained, which it can be if there are no large openings in the cover.

The spaces between the frames should be covered with a cloth, a clean woolen cloth preferred. Sticks about $\frac{3}{8}$ of an inch square should be placed crosswise of the frames to hold the cloth up so that the bees can pass over the tops of the frames. But I think that the bee-keepers will find to their cost that any device to hold the cloth up from the frames, so as to leave a large space, is a bad thing. However, a large space above the chaff is quite necessary.

Again, with so large an entrance it is necessary to leave a board against the front of the hive to keep out sunshine and wind. Or an alighting board 8 inches wide may have projecting arms 2 inches wide nailed to each end and fastened to the sides of the hive by two nails or wooden pins on each side, which can be taken out and the board lifted up and fastened to the body of the hive, so as to keep out sunshine and wind. This is a device that all bee-keepers will appreciate, and it is free for all to use. It will be attached to my *new hive* which I shall shortly introduce to bee-keepers.

In out-door wintering, all sides of the hive should be protected by 3 or 4 inches of sawdust or chaff, or the combs should all be taken out but five, and these should have passage ways cut through them and wooden tubes inserted. If this is not done the bees will often close up the openings made before winter sets in. Put a division board each side of the five combs, and fill the spaces between them and the sides of the hive with loose chaff. It will be found cheaper to do this than to make chaff cushions for the purpose. This latter method of protection is not easily carried out except in shallow hives, but it is believed to be cheaper than to use an outside case for a hive to be filled in with packing. The five combs should be spaced one-half inch apart, and contain not less than 5 lbs. of honey each.

Bees can be wintered in ordinary winters by various methods, but the great question with bee-keepers is, not what plans of ventilation and protection sometimes succeed, but what plan will secure the most "favorable conditions" so that the bees may be able to resist the vicissitudes of a very hard winter as well as a mild one, if it should happen to come. It is thought that the methods here given will secure these "conditions" as far as it is possible to afford them in out-door wintering. But I would place more stress upon the mode of ventilation and the management given than upon the amount of protection. Yet it would not do to abandon all protection, even if it could be done without loss, for the protection afforded will amply repay the time and labor taken to give it, in the saving of stores to the colony. It may be added, that the preparation of a hive of bees on the summer stand for winter requires as much, or more labor to do it as it should be done than to carry hives into cellars. Yet there is no doubt, in my mind, that out-door wintering will give the best results, unless at points far North, where the cellar or bee-house is preferable.

New Philadelphia, Ohio.

For the American Bee Journal.

How I Winter My Bees.

H. R. BOARDMAN.

Judging from the numerous articles in the bee papers upon the subject of wintering our bees, one would justly conclude that we ought to be able to surmount all of the difficulties that have heretofore existed, but from the numerous inquiries I have received of late upon that subject, it is evident that with the average bee-keeper, wintering is attended with much uncertainty, and disastrous losses are not uncommon even with those who have had many years of experience.

In view of these facts, I shall not attempt to tell you how to winter your bees, but will describe as well as I can how I winter mine, and in doing so, I am aware that I shall run against the pet theories of many very substantial bee masters.

The bee house in which I winter my bees will first claim a brief notice. The building is double-walled, packed with seasoned sawdust 12 inches thick, with sawdust also on the floor over-head, making it frost proof. It is divided into two or more rooms, one of which is used for an ante-room between the bee room and the outside, and also through which the air must pass before reaching the bees, and thus modifying it *a la* sub-earth ventilation.

The house I have used longest has three rooms, two in which to store the bees with the ante-room between. This room also contains a stove used for raising the temperature, expelling the moisture, and facilitating ventilation whenever occasion requires. A scuttle opens into the chamber

from the ante-room. The chamber is ventilated by a window in each gable, all of which may be opened or closed at pleasure.

The ground floor is cemented upon a layer of pounded stone, and is as firm as a rock, thus preventing any disturbance by jarring.

The windows are small, and provided with shutters inside by which the rooms can be made perfectly dark. The doors are also double.

The hive I use is a deep 8-frame hive, flat, movable cover on top, open bottoms, $\frac{3}{8}$ inch bee space on top of the frames under the cover.

I prefer that bees breed as late as possible, and go into winter with plenty of young bees, a good queen, and plenty of sealed stores gathered in the forepart of the season. I disturb them as little as possible late in the season, after they are disposed to become dormant.

I set them into the bee house as near Nov. 15 as the weather will permit, and let them remain until April 15, if favorable conditions can be maintained. I choose a cool, not a cold still day, having previously prepared the rooms by covering the floor with seasoned sawdust, then having lettered and numbered the hives with a piece of white chalk, so as to render mistakes impossible in setting them out on the same stands again. I take each hive up from the bottom-board or stand, and carry them into the bee house, and set them upon stringers previously placed there to receive them, so that when so placed the air has free access beneath the hives which are bottomless.

Having placed one row around the outside, I lay stringers on the top of these upon which I set another row of hives, and so on as high as I can conveniently set them. I use 2x4 inch stringers on the bottom, and one inch on top of the hives. A thermometer is hung in each room, and a careful record kept of the temperature in the rooms and also outside, visiting the rooms at least once each day for that purpose, noting also anything I may think important.

The hives are only ventilated at the bottom. The rooms are kept well ventilated, and at a temperature averaging near 45° somewhat below in the forepart of the winter, and above in the latter part. After being set in, the bees remain very quiet until sometime in February, unless disturbed by an unusual warm spell.

Sometime in February there will be a noticeable increased activity, and the thermometer will indicate a higher temperature. This is an indication that brood rearing has commenced. If the weather continues warm for a long time, and the bees become very uneasy, I sometimes set them out at this season for a flight, but consider it of no benefit if the temperature can be kept under control, which I endeavor to accomplish by opening the outside doors at night and close them in the day time.

I have observed that when the temperature is quite low for a considerable time, after brood-rearing has commenced, that a bad condition is

almost sure to follow, and dysentery and spring dwindling is often the result. Therefore, I am careful at this time to see that the temperature continues favorable for the brood, and the result is a hive full of bees when setting out in the spring, and a considerable portion of them young.

If the temperature is inclined to continue too low, I resort to artificial heat, and from several years experience, I am satisfied that there is no means of ventilation equal to it, and with judicious use I think it will always be attended with good results.

When the flowers of spring come and the bees can find employment gathering pollen and honey, I feel that the time has come to set them out. Then on a warm pleasant day I set them each out upon the stand from whence they were taken in the fall, and the warmer and pleasanter the weather the finer will be the condition of the bees. But if the weather is cold and damp, when they are set out, a bad condition will be induced however perfectly they may have been wintered.

East Townsend, O., Sept. 24, 1883.

For the American Bee Journal.

The Problem of Wintering Bees.

JAMES HEDDON.

We have been told by some of our brothers in apiculture, that "cold" was the cause of dysentery in bees. When their "cold" theory was shaken up, a little of it had to go into partnership with "confinement" to make it stand up, and with a more thorough shaking they both fell to the ground. The same is true of the "confinement" theory put into company with "cold." Our friend, Dr. Tinker, struck out on the "humidity" or "dampness" theory, and one shaking has caused this to stagger up against the "cold," and if we continue the agitation, will they not tumble hand-in-hand?

Now, Mr. Balch's cellar, from whence came the damp and moldy hives all free from dysentery, was kept at a lower temperature than mine; so dry that sack salt would hardly show moisture, as several bee-keepers observed, and from whence came 45 out of 48 colonies dead with dysentery in its worst form, some of them dying within three weeks after being placed in there. Mr. Balch's hives were all damp and moldy *in situ*, and neither the hives or the cellar had what bee-keepers at large consider sufficient ventilation to keep the air decently pure.

It seems that Dr. Tinker has a double team too, and while he calls the bacteria and pollen theories my double hobby-horse team, he has one of the bacteria and humidity.

Well, there is no sin in honestly trying to get at the bottom of this great question, each one in his own way; and while I respect the Doctor for his efforts, I find that his team is wonderfully misnamed, that is, that the bacteria and humidity theory have no relation to each other, and do not

look as much alike as a black Norman and a lemon-colored mustang, and worst of all, the Doctor seems to think it is quite likely that this radical, and ever the same effect, dysentery, has two very unlike causes. This, I do not believe for one moment, I cannot. In the case of my 48 colonies, I had them ventilated some above radically, some in a medium degree, and some but little, many not at all; some in hives 13 cubic inches, and some 13 square and 17 deep, and 9 in the Doctor's 10-frame Langstroth. Every one of which died among the first. The very first one being one of these 10-frame Langstroth hives with medium upward ventilation, and containing an Italian queen, for which I paid Adam Grimm \$8.

Now, I do not believe that the shape of the hive, method of ventilation, or the queen of Mr. Grimm had anything to do in causing it, and in this dry cellar, where the mercury never went below the freezing point, and hardly below 44° F., neither or both combined could have produced it. Time after time have not only I, but scores of others had their apiaries terribly reduced by this malady, where neither cold nor dampness were present, nor Mr. Doolittle's long confinement. No; too many of us know that these theories are fallacious. Now, give your bees pure, properly prepared, refined cane sugar syrup in combs containing no bee bread, in such shape that they can reach it readily at all times, and then, if the disease mows down our colonies, as it has been doing, I will agree to run for president of an indignation society, which meets semi-occasionally to expatiate upon our universal ignorance. I have before shown how nearly alike is the pollen and bacteria theories. When producers get the sticky and doubly interesting habit of setting their sections down on the brood frames, I will make every effort possible to see that Dr. Tinker, of New Philadelphia, the introducer of the golden-honey plant, has the great credit that will certainly be due him.

Now, it is my turn to get into the quagmire of not comprehending how lots of top surface and surplus case room can work favorably to the safe wintering of bees, especially as so many bee-keepers have declared against the 10-frame Langstroth hive for this very reason, and further, because most of us still persist in removing our surplus cases at the end of the surplus season, and substituting in its place a box whose top surface room is more than 6,000 cubic inches, and yet the bees will get the dysentery and die. Nearly every year since I adopted the 8-frame Langstroth hive, I have been cursed with some 10-frame hives, and strange to say, they have fallen behind the average of my apiary, in wintering safely.

My opinion is this, bees are more inclined to let alone the nitrogenous food, bee bread, and use only the oxygenized food, honey, when they have the best of facilities to get at their stores at will. If the Doctor can tell us how bees can more readily get

access to the adequate amount of food required to winter them, said food being distributed through ten combs instead of eight, then I will not only feel under obligations to him, but will go back and impoverish Mr. George and Katie Grimm, by showing them that their parent's bank stock accumulated from the use of bees in 8-frame hives is all a myth, because it is now clearly shown that said hives will not winter bees (though Adam beat all the bee-keepers of this country in safely wintering large numbers of colonies in his), nor are they well suited to surplus storing, though tons are annually coming from their tops, and the change from the 10 to the 8-frame hive is as sure as the trial is made.

I believe I ventured to predict that more than likely disease would catch the Doctor before old age overtook him and soothed him to sleep. I would rather it would be otherwise with all who live, but, alas, it is only the very rare exception. I do not ask, nor expect the readers to place any more confidence in my theories and statistics regarding this wintering problem than they do in my "amazing" little prophecy.

"There is a history in all men's lives,
Figuring the nature of the times diseased;
The which observed, a man may prophesy,
With a near aim, of the main chance of things,
As yet not come to life, which in their seeds,
And weak beginnings, lie untrea-sured."

Dowagiac, Mich., Oct. 3, 1883.

For the American Bee Journal.

Introducing Queens.

J. E. FOND, JR.

From my own experiments, I am led to believe that queens may be introduced safely with far less trouble than is usually taken in the operation. If the conditions are right, queens may be allowed to run into hives without taking any precautions whatever, and will be accepted at once; unless the conditions are right, queens will not be accepted, no matter what precautions are taken.

We all well know that it is a great injury to a colony to be without a laying queen for several days, and if this can be avoided, very substantial gains will be made in the amount of the honey crop. That there is no absolutely safe method of introducing queens as yet discovered, is true; it is also true that it is very difficult to determine when the conditions are such that a queen will be accepted. In my experiments I have taken all these matters into consideration, and find that the occasional loss of a queen, made by introducing her at once when the old one is removed, is more, far more than counter-balanced by the gain in not allowing the colony to remain queenless an hour. I have particular reference to the time when honey is being gathered freely, as that is the time when the loss of a queen is severely felt. In introducing a queen, I now adopt no precautions whatever, except in early spring and fall, but simply remove the old queen, and allow the new one to run into the entrance.

My theory is this: Before removing the old queen, I give the colony a few puffs of smoke to quiet them. The bees at once fill themselves with honey, and are as amiable as one could wish; the bees coming in from the fields are filled with honey also, and the foragers besides are so occupied with their honey gathering propensities that they take no notice of what is going on inside the hives, and as the comb builders and nurses are all very young, they do not molest the new queen, even if they do take any notice of her. My theory may not be correct, but the fact is that I do not lose one queen in 10 by introducing in this manner.

When no honey is being gathered, queens cannot be introduced safely in this way. The old bees remain in the hive, and are terribly vexed at not being able to gather stores, consequently are ready to vent their spite upon any thing that crosses their path. I have, however, in several instances, introduced queens successfully in late fall, by the method advised by Mr. Simmins in the *British Bee Journal*, viz.: removing the old queen, and at once placing the new one upon the same place on the comb the old one was taken from. I am of the opinion that the actions of the new queen have, to a great extent, a bearing upon the matter of whether she is well received or not; if she is scared and runs from the bees, or shows any symptoms of terror, she will be pounced upon at once; otherwise she will hardly be noticed. My reason for allowing queens to run in at the entrance, as mentioned above, is that I think they are not as apt to show signs of fear, or by any acts of theirs cause the bees to see that they are strangers.

Perhaps I may be considered as decidedly heretical, but I have never been fully satisfied that colonies have any scent peculiar to themselves, by which they are enabled to distinguish visitors from members of their own colony. The idea has always seemed to me as somewhat fanciful; more particularly when I see that robbers are recognized before they touch the alighting board, and by their actions rather than by anything peculiar about them. I have often seen sentinel bees "go for" robbers, when they were nearly a foot from the entrance; and I have seen them oftentimes pounce upon a bee at the entrance, and finding it showed no signs of fear, allow it to go peaceably in when one that did show signs of fear (as robbers always do when pounced upon), was ruthlessly destroyed. This question of peculiar scent is a matter of opinion with me; but is it any more than a matter of opinion with others? If there is any evidence of the fact, if it is a fact, I hope yet to see it, and until I do, shall hold to my present belief.

Foxboro, Mass., Sept. 28, 1883.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Western Bee-Keepers' Convention.

The Western Bee-Keepers' Association met at Independence, Mo., Sept. 20 and 21. The attendance was good, better than at any of the previous meetings of the association, and the first day's session was spent most pleasantly.

The morning passed in arranging the displays of bees, honey, extractors, hives and fixtures, and in a general social manner. At noon, those in attendance, were treated to an excellent repast by the ladies of the association. After dinner the tables were cleared and the association was called to order by its president, Mr. Jas. A. Nelson. Mr. P. Baldwin acting as secretary *pro tem*. The reading of the minutes was deferred until next day.

No preliminary remarks were made, and the association proceeded to the business in hand. The committee on subscriptions to a premium by the citizens reported an amount of \$50 subscribed for the best 50 pounds of honey. The committee on premiums offered by the association reported as follows with names of exhibitors:

Class A.—Best display of comb and extracted honey, 20 pounds each, \$25; W. C. Haroldson and Jonathan George.

Class B.—Best 25 pounds of comb honey, \$10; W. C. Haroldson, Jonathan George and Miss R. A. Baldwin.

Class C.—Best 25 pounds of extracted honey, \$10; J. T. Sale, Willie Baldwin, W. C. Haroldson and Jonathan George.

Class D.—Best queen with her bees, \$10; W. C. Haroldson and J. H. Fink.

Class E.—Best display of bee fixtures, Scoville & Anderson, Columbus, Kansas.

Those contending for special premium of \$50 on exhibit of 50 pounds of honey, are L. W. Baldwin, Jas. Jones and P. Baldwin.

Class G.—Best package of comb honey, one year's subscription to the *Independence Sentinel*, Willie Baldwin.

The report of the committee was followed by the election of officers for the ensuing year, as follows: President, H. Scoville, Columbus, Kansas; Vice-President, G. W. Young, Lexington, Mo.; Secretary, C. M. Crandall, city; Treasurer, P. Baldwin, city.

No further business was transacted at the afternoon session.

Quite a number of the citizens joined the members in making the day's meeting a success. Among those present from other places were, Messrs. J. T. Sales, Jas. Jones and their ladies, of the country; Mr. John Long, of South Missonri; Mr. Jas. A. Nelson, of Wyandotte, Kas; Messrs. G. W. Young and C. F. Lane, of Lexington; Messrs. Scoville and Anderson, of Columbus, Kas., and also Miss Millie Scoville, of Columbus, Kas., who is a guest of Capt. Jas. D. Meador's family.

The second and last day's session of the annual meeting of the Western Bee-Keepers' Association was even more productive of discussion and general interest than the first day. The attendance was larger, and all

in all, the association may be congratulated upon its success at this the second meeting since its organization. The premiums were ample for the meeting, but with the present rate of increase in interest and endeavors for success will necessarily be larger at the next meeting. More visitors were present yesterday.

On Thursday evening, at 8 o'clock, the association met for discussion with President Scoville in the chair. The evening, which was very satisfactorily spent, was opened by adopting a resolution, offered by Capt. Jas. D. Meador, to present a crate of the premium honey to the *Journal*. This was followed by voting a half crate of the premium honey to the *Independence Sentinel*, and also to the *Independence Progress*.

The President appointed Mr. P. Baldwin committee on statistics. Dr. G. W. Young occupied some little time in addressing the meeting. He was followed by President Scoville with his experience in bee-culture. Raising queens from worker eggs, and his method of swarming bees were the topics. To swarm bees he advised the taking of a small nucleus from each hive and strengthening from the stronger colonies from time to time.

The subject, "What causes comb honey to sweat and run," was discussed by Messrs. P. and L. W. Baldwin, J. D. Meador, G. W. Young, H. Scoville and C. M. Crandall. The conclusion was that it was caused by the bees sealing the honey before it was properly ripened.

Mr. P. Baldwin propounded the question, "What does the worker bee do with the honey when first brought into the hive?" The answering of the question was not fully arrived at, and the discussion was rather animated and engaged in by all the members. The best method of marketing honey was freely discussed by Messrs. Baldwin, Meador, Jones and Young, and was postponed for further discussion until next day.

Friday morning was occupied in a social way. The members took pains to explain all the fixtures and in exhibiting the fine display of honey to the many visitors who called during the day. At 1 o'clock dinner was served as on the previous day, and those in attendance were highly pleased at the efforts of the ladies who prepared the repast.

AFTERNOON SESSION.

President Scoville called the meeting to order shortly before 2 o'clock, and called for reading of the minutes of the previous meeting, which had been deferred. They were read and adopted.

The report of the judge who had awarded the premiums was called for, and read as follows, Mr. Jerome Twitchell, of Kansas City, officiating as judge:

Class A.—Best display of comb and extracted honey, to W. C. Haroldson, Buckner, Mo.; premium, \$25.

Class B.—Best 25 lbs. of comb honey, to Miss Rosina A. Baldwin, Independence; \$10.

Class C—Best 25 lbs. of extracted honey, to W. C. Haroldson, Buckner; \$10.

Class D—Best queen and bees, J. H. Fink, Independence; \$10.

Class E—Best display of bee fixtures, Scoville & Anderson, Columbus, Kas.; \$15.

Class F—Special premium No. 1, by merchants of Independence, best 50 lbs. of honey, to Jas. A. Jones, Buckner; premium, \$50.

Class G—Special premium No. 2, one year's subscription to the Independence *Sentinel*, Willie Baldwin.

The discussion of the best methods of shipping and marketing honey, followed the awarding of the premiums. It was engaged in by Mr. Jerome Twitchell, of Kansas City, who spoke at length, and was quite interesting, although he, as well as the others, was uncertain as to the best methods.

Mr. Phidel Baldwin, of the committee on statistics, reported as follows. The Table will explain itself:

NAMES.	No. of Colonies in Spring.	No. of Colonies in Fall.	Pounds of Comb Honey.	Pounds of Extract Honey.	Beeswax.
W. C. Haroldson.....	40	80	2000	150	...
Young & Lane.....	175	475	3000	500	100
J. H. Fink.....	3	8	...	55	...
Elias Ellis.....	10	20	400	300	5
Jas. T. Lisle.....	12	16	200	500	...
C. M. Crandall.....	57	85	2000	800	25
Scoville & Anderson.....	135	150	...	1500	50
L. W. Baldwin.....	175	230	8750	2750	50
Jas. A. Nelson.....	54	64	300	3000	25
Jas. D. Mendor.....	20	54	...	2000	100
Jas. H. Jones.....	85	110	5400	1200	46
Samuel D. Gregg.....	20	26	500	1200	50
P. J. Farr.....	125	150	4800	1500	15
Jonathan George.....	58	84	2300	1000	20
Phidel Baldwin.....	125	165	8500	1000	25
W. B. Thorne.....	18	30	400	900	...
Total.....	1112	1739	38550	19355	261

Jas. A. Nelson, Wyandott, Kas., and Scoville & Anderson, Columbus, Kas., reported that they were principally in the queen rearing business.

On motion, the President appointed Messrs. Phidel, L. W. Baldwin and Jas. H. Jones a committee on marketing of honey.

At 4 o'clock the second annual meeting of the Western Bee-Keepers' Association adjourned, to meet at a semi-annual meeting on the last Thursday in April, 1884.

C. M. CRANDALL, Sec.

H. L. SCOVILLE, Pres.

For the American Bee Journal.

Central Michigan Convention.

The Central Michigan bee keepers held a meeting in the Pioneer room, in the State Capitol building, on Sept. 25; about 20 members were present. President Ashworth occupied the chair. S. Hilbert, of Lansing, was made a member.

In discussing the best methods of wintering, J. M. Harper, who had looked upon the cellar, as the best plan, confessed to a change of mind. He found it difficult to secure proper ventilation in the cellar, and would winter a part of his bees in chaff hives; he believed, upon the whole, that

there is less risk in wintering in chaff hives than in the cellar.

Prof. Cook thought the entrance to the hive should be nearly closed, at this time of the year, so as to keep the brood from chilling. He also said that a great many of our best bee-keepers are using finer packing, such as timothy, chaff, and very fine sawdust; he did not want oil-cloth over his bees at any time; he also said that in cellar wintering the bees ought not to be taken out before April 5, and, in preparing them for winter, he would take away all the pollen he could.

J. M. Harper thought it time now to prepare for winter.

A. Gregory thought it too early, as there would be danger in not leaving honey enough.

Superintendent I. N. Smith, and Secretary B. B. Baker, of the Central Michigan Agricultural Society, were present, and stated that suitable arrangements had been made for an exhibit of bees, honey and apiarian supplies at the coming Fair.

Prof. Cook recommended an application of ammonia or sal soda for bee stings.

O. Wilson endorsed the ammonia remedy.

On the question of profit, Mr. Hilbert thought bees as profitable as any investment he could make.

W. B. Stone & Co., had a fine display of hives, extractors, smokers, and comb foundation, and stated that they had sold during the season, 150,000 of the all-in-one-piece sections, and about 700 of the Baker hives.

The next meeting of the Association will be held at the same place in Lansing, April 18, 1884.

E. N. WOOD, Sec.

Lansing, Mich.

Experiments in Introducing Queens.

A. M. HOGLE.

I bought 2 colonies of black bees to manipulate while learning my first lessons in bee-keeping, transferred them to Langstroth hives in May, 1883, which were the first movable frame hives that I ever saw. In June I tried to Italianize them; 48 hours after I put the first Italian queen in the hive, I let her out of the cage, and the natives balled her; I re-caged the queen, but in 24 hours more they had cut under and killed her. The second Italian queen arrived dead; for the third, I selected 5 frames of hatching brood (brushed the old bees off), put them in a new Langstroth hive with my fine queen, and the ants destroyed the queen and colony. The fourth and last queen came in a 3-frame nucleus colony. I have 8 fine queens from her, and 3 queens from my 2 blacks, which make me 1 Italian, 8 hybrids, and 5 black colonies, making 14 colonies in all; increased only 11. My box hive and log gum neighbors have done well. Mr. B. had 4 colonies, increased to 5; Mr. R. 1 colony, and no increase; Col. B. 25 colonies, increased to 26; Mr. M. 1

colony, and no increase; Mrs. R. 2 colonies, and no increase; Mr. G. 23 colonies, increased to 25; Mr. W. 3 colonies, and no increase; spring count, 59; increase, 4. Some of them are almost persuaded to take the BEE JOURNAL and adopt the Langstroth hive.

Morgan, Texas, Sept. 27, 1883.

For the American Bee Journal.

Bee-Keeping in Bucks County, Pa.

J. E.

I enclose a flower and stem of a weed that grows in our fields at this time of the year, and has several shoots. Yesterday I counted 16 Italian bees working on a bunch at the same time, and the humming of the bees among the flowers of that weed, sounds like it does in May. What is its name? Does it produce honey abundantly, and of what quality? as the bees seem to work on it from early morning until late in the evening.

Bees in this section of the country, as far as I have heard, have done well for the season. The forepart was very wet, the latter part very dry. Surplus comb honey has been taken abundantly, and retails at 25 cents readily; but no extracting is done in this neighborhood, where box hives are mostly used; some have reported an average of 50 pounds to the hive. I cannot report, this season, anything on my apiary, as I have transferred my bees from old hives to movable frames, and introduced bees from the apiary of D. A. Pike, of Smithsburg, Md., and I think they are the best and gentlest bees to handle, and are as good honey-gatherers I ever saw during my 25 years of keeping bees. I procured over 30 pounds from one hive, from May 1, 1883, to June 1, 1883, after turning them upside down.

These last two months being so dry, the bees do not seem to store any surplus from fall flowers, but seem to have plenty of sealed honey in the body of the hive, and take what they gather at present for brood-rearing, as there seems to be more for this month than I have seen in several years, for the same month.

The Italians have not been clear of drones this season; they are flying every day, while the blacks disappeared in July.

Fallsington, Pa.

[It is an aster; it yields honey abundantly, and of fine quality.—ED.]

Desiccated Foul Brood.

H. L. JEFFREY.

I send, by mail, a sample of that species of foul brood that I have tried so hard for the past five years to obtain some information about, from other bee-keepers, without any result.

The larva turns yellowish brown, and then dries up and leaves a dirty sediment in the cells. My attention was called to it on Monday, Aug. 3.

It is not usually noticed till the colony has all dwindled down. The queen keeps laying in the combs nearly as well as usual, but the third or fourth lot of brood does not mature as much as the preceding ones, and if a comb is taken from the hive and given to healthy colony, every comb will be more or less affected with it in two or three months, and it will spread all through the apiary in one or two seasons, according to the number of colonies. The infection seems to stay in the hives unless they are thoroughly washed inside with salt and vinegar. In 1880 and 1881 I saw 25 colonies in one yard ruined by it. I have known of its ravages since 1878, in different parts of this State. I never have had but three or four hives troubled with it, and those were in an isolated apiary for the purpose of experimenting, but it has shown itself in several apiaries where there has been a large amount of bare-headed brood, during the previous season.

I have been as far as 35 miles, by request, to examine colonies that I have found it in, and found it the cause of the colonies being depleted to a serious extent. I am sure it is as much to be dreaded as the malignant foul brood, because it is not as easily detected in its first stages, and for that reason it easily and surely gets the upper hands of the novice, and its ravages get a good foot hold.

Please to examine the specimen as closely as possible, and call the attention of the best informed apiarists to the subject. I am ready to give all the information I possess on the subject, and would like the opinion of others. Perhaps if the specimen was examined by some competent apiarists, it would be more thoroughly investigated.

Washington Depot, Ct.

[We have had no experience with foul brood in any form, but will try to get the opinion of those who have, at the Convention here next week.—ED.]

For the American Bee Journal.

Bees Injured by Heat, etc.

J. D. ENAS.

Under the heading of "Bees Injured by heat," Mr. M. Bragg seems to think that my bees suffered from not being properly shaded. Most of my hives are not shaded, though I am not opposed to shade for hives; I have planted some trees for that purpose, and have used the live oak for shade, but do not observe any difference in the result. When bees cluster at the entrance, I find out the reason at once, and attend to it.

My hives are the Muth-Langstroth, with false ends, for the frames in the second story, which gives an air space at the ends of frames, and prevents the combs from melting, and the overheating of the brood. It is a long time since I had any combs to melt from heat. I use a piece of burlap on the top of the frames, which absorbs

moisture, and keeps the top of the hive cool in warm days. I also raise the top and also the hive from the bottom board, if needed.

On the last of December, 1882, we had a down-East snow storm; snow was six inches deep on a level, with frost in the evening. Previous to that our season was warm, and fruit buds were nearly in bloom. One could see the pink lining to the cherry buds. Many of our fall and winter flowers were in bloom; even blue sage, which was killed by the snow and subsequent frost. The snow did not last 48 hours. The Manzanita, which was in full bloom, was cut short. Fruit buds that were about to burst were checked, and none too soon, for every thing would have been killed. All tender plants were killed to the ground; even the live oaks shed their leaves, some entirely, which is unusual, and which I have not seen before, during a residence of more than 31 years in this State.

In February again, during a warm spell, the Sage bloomed, to be again caught by frost, which checked the rearing of brood. Having plenty of combs of sealed honey, I uncapped it and gave it when it was most needed. We had a good many cool and sudden showers until May, when the bees were booming again, though the weather was very bad for queen rearing most of the spring, as it seemed to rain just when one expected a lot of queen cells to hatch, or a lot of young queens to be fertilized.

Early in June we had north winds which dried up vegetation, injured the bloom and young fruit, and put another check on the honey flow, and the effect was felt the balance of the season throughout the State.

Our climate is not the same as at Mr. Bragg's place, which is probably 100 miles, or so, further south. The highest marked by the thermometer was 102°, and that for one day only. That was the only time that the bees left the combs; but by raising the hive from the bottom board, they soon went inside. I used the entrance of the whole width of the front of the hive. I am of the same opinion as Mr. Bragg, that a double-walled hive will suit this climate. I think the dead-air space an improvement, to guard against over-heating.

Queens stopped laying from 4 to 6 weeks, but are building up, at the present. I had to feed 100 pounds of sugar. They are doing better now, and prospering. The frost stopped the supply of pollen.

At the time my bees were getting reduced, they did not seem to be bringing in pollen, and by feeding them honey liquefied, I induced robbing more than I cared for (although I had a bee tent). After using all means to stop robbing without success, I made a lower story to the hive, only 1½ inches high, well ventilated with double-wire cloth over the ventilators, with a trap for entrance, so that the bees could go in, but not get out. I set the hive on that, and closed all the openings except the entrance.

I had a hole one-half way up, in front of the hive, and closed with a

plug. When the robbers were very thick at the entrance, I opened the upper hole, and they would stream in, in a solid body; when most were in, I closed the hole. In this way I got a strong colony. I then placed an empty hive on the stand, and removed the hive with bees, shaded them for several days, and put them on their stands after dark. The next morning they were ready to defend what they had before robbed. I think the other hives were more than the loser. This is the worst season I have seen since 1877.

Napa, Cal., Sept. 17, 1883.

For the American Bee Journal.

Ohio Convention.

The Ohio Bee-Keepers' Association held a meeting at Columbus, O., from Sept. 3d to 7th inclusive, during the Ohio State Fair, at which time several questions of importance were discussed, among which was the subject of Queen Rearing and Management, by A. Benedict, of Benington, O.

Also by S. D. Riegel, of Adelphi, O., on Rearing Queens from Larvæ, Rearing Queens in Small Nuclei, and Putting Queens with Swarms at Swarming Time, etc.

A question was asked and not satisfactorily answered, Will a Colony Swarm without Drones?

Many other questions of importance were discussed.

An interesting lecture was delivered by Dr. Besse, of Delaware, O.

I must not close this report without thanking the Ohio State Board of Agriculture for the interest they have taken in the advancement of bee-culture, by the liberal premiums paid, and suitable buildings provided for the display of honey and all kinds of bee appliances, of which there was a very good display by Dr. Besse, S. D. Riegel, A. Benedict, Mr. Drum and many others.

The meeting adjourned to meet some time during the winter, of which due notice will be given.

C. M. KINGSBURY, Sec.

The fall meeting of the New Jersey and Eastern Bee-Keepers' Association will be held in the city of New York, at the Cooper Union, on Wednesday, Nov. 7, 1883.

J. HASBROUCK, Sec.

Bound Brook, N. J.

The Lorain County Bee-Keepers' Association will meet at Oberlin, Ohio, on the last Tuesday in October, 30th.

O. J. TERRELL, Sec.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Do not let your numbers of the BEE JOURNAL for 1883 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

If I understand correctly, this department is not expected to occupy very much of each number of the Weekly. It is, in my judgment, intended to be filled with these questions, that are of such a nature that short answers may be full and comprehensive. There is an old adage that makes the following new one true. A moment may ask questions that hours cannot answer. For instance, "A Friend's" first question is exactly adapted to the department. His second will do.

Mr. Tongue's, in my opinion, is out of place here. It would take a long and comprehensive article for me to reply to it satisfactorily to Mr. T., and then some one else would call it all moonshine.

None but the author should dictate the subject for articles. Articles to be of most value, should have some inspiration about them. Inspiration (excelerated circulation), will not bear dictation.

How is this, Mr. Editor, am I not correct? You made this department, and had it all before my eyes, in print, before I dreamed of such a thing.

J. H.

[Mr. Heddon is quite correct. The department was intended for terse replies, of general interest, and not for a special description of articles, used by Mr. Heddon, or for captious questions regarding any of his "hobbies," for every man has more or less of them.—ED.]

Spaces Between Tiers of Sections.

Will Mr Heddon please answer? 1. How much space do you allow between the tiers of sections in your case?

2. About what per cent. of your sections can you get straight enough to glass?

A FRIEND.

ANSWERS.—1. Scant $\frac{3}{8}$ of an inch.

2. Without separators, we can get 5-6 of our sections straight enough to glass, if we glass them on the outside of the wide pieces, *a la* Moore; but if on the outside of the narrow pieces, and within the wide side pieces, then only a small portion, and were I bound to glass my sections in this style (prize), I should use separators.

How to Successfully Winter Bees.

Will Mr. Heddon please tell how to winter bees successfully in the "What and How." It will be a favor thankfully received. Please give *modus operandi* in detail. L. N. TONGUE. Hillsborough, Wis., Sept. 22, 1883.

ANSWER.—While I appreciate the fact that Mr. Tongue values my knowledge of the wintering problem, I wish to say that the best I can do for him now, is to refer him to my illustrated article in one of the October numbers of the Weekly for 1882. I am now making some extensive experiments in wintering, but of these cannot report much yet.

Sections and Cases.

Will Mr. Heddon please answer the following question in the BEE JOURNAL:

1. Is your section 2 inches wide or $1\frac{3}{4}$ inches?

2. How is the Heddon section case made?

3. Can the section be glassed as easily as if separators were used?

J. F. SELLERS.

Reynolds, Ill., Sept. 11, 1883.

ANSWER.—1. We are this year experimenting with sections $1\frac{1}{2}$, $1\frac{3}{4}$ and 2 inches wide; they please us just in proportion to their width—preference being for the narrowest.

2. Our case is a shallow box, with open top and bottom, $4\frac{5}{8}$ high, of the length and breadth of the hive they are to be used on, with partitions and a tin strip on the bottom to support the sections. The minutia is out of place here, and you should not attempt to make any number without a sample.

3. The sections cannot be glassed as readily as those built between separators.

SELECTIONS FROM OUR LETTER BOX

Best Honey Season for Years.

We have not had time to take off all our honey yet. There are at least 2,000 pounds yet in the hives. We have had the best season for honey that we have had for some years. Bees are now working briskly. Our bees will be in splendid condition for winter quarters.

S. VALENTINE & SON.

Hagerstown, Md., Sept. 28, 1883.

Fall Honey in Texas.

We have had a very good rain down here, and grass has started up. The bees are doing very little, working on scattering wild flowers.

M. C. GRANBERRY.

Austin, Texas, Sept. 30, 1883.

Good Qualities in Bees.

On page 480, I noticed the following list of qualities which should be sought in bees: 1. Good honey gatherers. 2. Hardy to winter. 3. Easy to handle. 4. Yellow bands. Please tell us of what value is the fourth requisite to these perfect bees. It seems to us that to the three first qualities should be added, good comb builders, and the instinct to protect themselves from robbers, moths, etc. There may be many other valuable qualities, such as, prolificness, but we can see no possible use of "yellow bands." Had the writer said "iron bands," we might have thought he wanted them to keep the over-loaded bees from bursting. If these "yellow bands" are something of that kind, we hope the phenomenon will be explained.

JOHN KING.

Fowler, Ohio, Sept. 25, 1883.

[The remarks about "iron bands" are, of course, simply "irony"—nothing more.

Yellow bands merely add to the beauty of the bees; and, though this is always a welcome feature, the qualities named above, for comb building, prolificness, etc., are more essential.—ED.]

Those Large Yields.

Please ask, through the BEE JOURNAL, of those giving large yields from one colony, to give a description of their hive, the surplus honey, kind of bees, if doubled in the spring, how much, whether fed or not, if fed, when and how much; also the treatment from Nov. 1, 1882, to the time of their report.

T. J. TIFFANY.

Brooklyn, Pa., Sept. 30, 1883.

Asters as Honey Plants.

I send a sample of one of our honey plants, and would like for Prof. Cook to give us the name of it through the BEE JOURNAL. It generally grows about 4 feet high, and sometimes 6 feet. It has been in bloom ever since Sept. 1, but it is about out now. The bees have worked on it splendidly, and stored a nice lot of honey, putting them in fine condition for winter.

A. R. NISBET.

Dobyville, Ark., Sept. 29, 1883.

[It is one of the innumerable asters, which are among our most excellent honey plants. The honey is also of excellent quality.—A. J. COOK.]

Satisfied with Honey Crop.

I have just taken off the last honey of the season, and put my bees into winter quarters by putting a large chaff cushion in my chaff hives, as I remove my crates. It may seem a little early, but my experience is, that it does not hurt them to have plenty of time to arrange for their "long winter nap." I found an unusual amount of brood and honey in the brood-chamber, for the time of year. Our fall honey was cut short by the drouth and early frosts, but my sea-

son's report is as follows, and I am satisfied: Spring count, 35 colonies; in winter quarters, 57 colonies; comb honey, 2,008 lbs.; extracted honey, 1,114 lbs.; total, 3,122 lbs. I hope to be able to attend the Chicago Convention.

GEO. E. HILTON.
Fremont, Mich., Oct. 3, 1883.

Fall Honey from the Asters.

Please find enclosed a flower that is just in full bloom now. It has been in bloom for about ten days; the frost does not seem to injure it. Bees are working on it very lively, and they are storing honey in good style yet. Please give it a name through your welcome BEE JOURNAL.

D. B. BROWN.
Des Moines, Iowa, Sept. 27, 1883.

[It is one of the asters—all are excellent honey producers.—Ed.]

Bee and Honey Exhibit.

We had quite a nice honey exhibit at the Portage County Fair. Mr. Page, of Streetsborough, and Mr. Converse, of Ravenna, were the exhibitors. Mr. Page had a tent made of wire screen covering his bees. Mr. Converse took out the side of his hive and put in glass, so that they could see the bees. He took the prize for a hive; also, on the best colony of bees; also on some honey.

B. HARDING.
Kent, Ohio, Oct. 1, 1883.

Bee Killer.

I send a specimen of fly caught with a bee in its forceps. They are exceedingly swift on the wing, and cannot be kept sight of more than a couple of rods away. Are they the "bee killers" spoken of in the BEE JOURNAL?

JAS. POINDEXTER.
Bloomington, Ill.

[Yes; it is the *Asilus Missouriensis*, or bee killer.—Ed.]

The sixth annual meeting of the Northern Michigan Bee-Keepers' Association will be held at Stone's Opera Hall, Sheridan, Montcalm county, Mich., on Tuesday and Wednesday, Oct. 9 and 10, to open at 10 a. m. of the first day. Evening sessions will be held, which will be interesting. At our last meeting it was requested that all interested in apiculture attend, and all who would, and could, furnish for exhibition apiarian supplies in the way of hives, extractors, implements used in the apiary, honey, honey-producing plants, and anything that would be interesting to a bee-keeper. Ample arrangements have been made to entertain all who will come. Let us have a general turn out, and see what we can learn one of the other. It will be a dull scholar who cannot profit by such a gathering. Feel assured we shall have an interesting time.

GEO. W. STANTON, Pres.
O. R. GOODNO, Sec.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00, or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper, shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter, on your label, notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a statement of account every week.

Trial Trip—25 Cents.

As the season for Fairs has arrived, and wishing to be able to reach several thousands of the old-fashioned bee-men, and by the aid of the BEE JOURNAL to lift them up to higher ground, adopting newer methods and progressive ideas, we make the following very liberal offer: We will send the Weekly BEE JOURNAL till Dec. 31, *on trial, for 25 cents*. In order to pay for getting up Clubs, we will give a copy of Fisher's Grain Tables, or Scribner's Lumber and Log Book, to any one who will send us five trial subscriptions (with \$1.25) for a club of ten we will give a cloth copy of Bees and Honey; for a club of 15, a cloth copy of the 7th edition of Cook's Manual of the Apiary; for a club of 25, we will present both the Manual and Bees and Honey. If any one wants these Books for nothing, here is an excellent opportunity to get them for a little exertion.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
" 100 colonies (220 pages)..... 1 50
" 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey at Fairs, will sell almost a fabulous quantity of it.

OLDEST BEE PAPER

THE AMERICAN BEE JOURNAL

VOL. XIX.

CHICAGO, ILL., OCTOBER 17, 1883.

No. 42.

THE AMERICAN
BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Honey Producing Plants.

Speaking of the apiarian exhibit of the Michigan State Fair, the *Country Gentleman* says:

One of the most interesting features of the exhibition, was a collection of honey-producing plants, pressed and mounted by C. M. Weed, a student at the Agricultural College. So well was the work done that the natural colors of the flowers were perfectly preserved. There were more than 50 specimens.

We have purchased the whole collection, and have them bound in a volume and placed in the BEE JOURNAL Museum, for the convenience of visitors.

We have received a copy of a new Bee Book, in German, by C. J. H. Gravenhorst, of Germany. It is published at 5 marks (\$1.25), by C. A. Schwetschke & Son, Braunschweig, Germany, and contains 250 large octavo illustrated pages. Mr. Gravenhorst is one of the most progressive of German apiarists, and his articles have been published in the AMERICAN BEE JOURNAL from time to time, on all the most interesting topics of the day.

Allen's New Feeder.—We have received one of these new bee feeders, and placed in the Museum. It is new, novel, and thoroughly practical.

Our honey-producers who have an eye upon a European market for honey, will be pleased to learn that several late shipments of comb honey from this country to Europe has resulted successfully.

Honey at the Indiana State Fair.

The *Indiana Farmer* has the following concerning the honey exhibit at the recent State Fair:

While the honey show at the State Fair was creditable to those who made the exhibit, nevertheless, it was a disgrace to the bee-keepers of Indiana; especially so after the bounteous yield of the past season. Several parties had written us to the effect that they would make a display of apiarian products, but failed at the eleventh hour. Yet it may be taken as a sign of encouragement that we were not permitted to walk away with the entire list of premiums.

Mr. A. Cox, of White Lick, Ind., did himself credit, securing first premium on comb honey in the most marketable shape, also on best display of honey from one apiary, and second premium on retail packages of extracted honey.

Mrs. Cox carried off the red ribbon for the best honey cake, while visiting bee-keepers carried off the cake; we can testify, from personal knowledge, that it was very eatable.

J. Hutchinson, of Worthington, Ind., showed some nice honey, the shape, however, being objectionable on account of the size of the boxes.

In the ladies' department, Mrs. Brown, of this city, secured the first on comb honey, and Mrs. Robbins second on extracted.

The *Northwestern Farmer* says that Mr. H. K. Beecham, of Acme, Mich., commenced the season with 40 colonies of bees, increased to 57, and took from them 4,000 pounds of honey, 700 pounds of which was comb honey. One colony gave 170 pounds of well ripened extracted honey, and another 70 pounds of comb honey.

Honey that will not candy is to my mind very dangerous for winter stores, as my experience proves. If your combs are filled with honey from honey dew, it will pay to extract it all and feed sugar syrup. As the extracted honey can be fed in the late spring and summer months for brood-rearing with impunity, there will be no loss of honey.—*Indiana Farmer*.

Died, at Augusta, Wis., Oct. 4, 1883, after a long and lingering illness, Lovina, wife of Dr. D. C. Spencer, aged 50 years. A life-long earnest Christian, a devoted wife and mother; "her end was peace."

The above notice is sent us for the BEE JOURNAL. Mrs. Spencer was for several years a successful and progressive apiarist, and many who attended the National Convention in Chicago, in 1879, as well as several other meetings, and formed her acquaintance, will receive the intelligence with profound sorrow, and will join us in condolence with Dr. Spencer in his sad bereavement.

The *Chicago Western Rural* has been enlarged to nearly double its former size. This improvement in the *Rural* which evidently places it at the head of any other paper of its kind in this or any other country, is only indicative of the rapid development of our agricultural and live stock interests.

T. B. Peterson & Brothers, Philadelphia, Pa., publish this day "GUY MANNERING," being the *Third Volume* of their new and cheap edition of "THE WAVERLEY NOVELS," BY SIR WALTER SCOTT, which will be completed in Twenty-six Weekly Volumes, each volume being a novel complete in itself, and one volume will be issued every Saturday until the whole are published. Price 15 cts.

New Catalogues.—We have received the following: Catalogue for 1883-84 of Pleasant Valley Nurseries of John S. Collins, Moorestown, N. J.

D. A. Jones, Beeton, Ont., Circular and Price List containing a revised essay on the wintering of bees.

Annual Catalogue of the State Agricultural College of Michigan, at Lansing.

Price List of the Fruit-Land Nursery of T. J. Ward, St. Mary's, Vigo County, Ind.

Bee-Keeping on this Continent.

In the *Toronto Globe* for Sept. 28, we notice the following editorial article on the recent North American Bee-Keepers' Convention in that city:

At the recent meeting there were representatives from the extreme points of the "sunny South" and the "frozen North." Florida and Manitoba were in conclave over the question of honey-production. In the bounty of nature, all over this broad continent there flows, in greater or less profusion, the luscious nectar of flowers, which only awaits the labors of the "busy bee," to be utilized for the service of man. Although Southern bee-keepers have some advantages over their Northern brethren, especially in the matter of wintering bees, yet, strange to say, in the honey yield the North excels the South. As though Providence would infuse extra sweetness into the lot of those who are subjected to the rigors of our northern winters, it is in these higher latitudes that the largest crops of honey are taken, and Canada, though pictured by many in more southern climes as a region of snow and ice, is the banner country of the world as to the production of honey.

One has only to survey such an exhibit of honey as was presented at the Toronto Industrial Exhibition, to realize the possibilities of bee-culture in this and other countries. The display which has been made comprised about \$30,000 worth of honey. If every county throughout Canada were made to yield say \$10,000 worth of honey annually, it is easy to see that an addition of one or two million dollars would thus be made to the national revenue. This is an exceedingly modest and moderate calculation, because there is hardly a county in the Dominion that is not capable of yielding ten times that amount of honey.

It would appear from the statements made at the recent Convention, that what is needed in order to harvest the vast honey crop which is going to waste year after year in this and in other countries, is a sufficient number of properly qualified bee-keepers. Bee-keeping is like other occupations, aptitude and education are essential to success in it. Persons unfamiliar with bee-keeping, will doubtless have been astonished on reading the reported proceedings of the recent Convention, to find how many details enter into the business, and what a large amount of skill is needed in order to its successful prosecution.

The necessity of a thorough education in bee-culture of those naturally adapted to it was a prominent point brought out at the recent convention, and the best way and means of securing it were thoroughly discussed. As the outcome of these discussions it was resolved that the time has fully come for the claims of bee-culture to be recognized by its being taught in all the agricultural colleges throughout North America. The Michigan Agricultural College is the only one in the United States that has a profes-

sor of apiculture. Prof. Cook, who ably fills that office, was present at the meeting which has just closed, and added greatly to the interest of the occasion. He has, the present year, a class of 40 students, and were every other agricultural college on the North American Continent to follow the example set by Michigan, a large army of bee-keepers would be in training for this important rural industry.

It may be stated that instruction in apiculture was contemplated by the founders of the Ontario Agricultural College in the original plan of that institution. It was provided in the programme of study that "there should be a bird and bee department," and without doubt it might be made a very valuable and useful one. The Ontario Bee-Keepers' Association, it is understood, intend to urge this matter on the attention of the Government, and we trust it may be found practicable to comply with their wish, and thus make our Agricultural College in this, as it is in most other respects, the peer of the one in the adjacent State of Michigan.

To the Bee-Keepers of Kentucky.

We are requested to publish the following Circular, a copy of which Dr. N. P. Allen will send to any one who will fill out the blanks and return to him:

We were appointed a committee by the Kentucky Bee-Keepers Association, which met at Louisville, August 29 and 30, to collect information in regard to bee-culture and honey production in Kentucky, the ultimate object being the development of the honey resources of the State, and the best location for apiaries.—N. P. Allen, W. C. Pelham, J. T. Conley.

Every bee-keeper is requested by the Committee to fill out the following blanks, and forward the same to me at Smith's Grove, Ky.

N. P. ALLEN, *Chairman Com.*

Seasonable Hints.

Prof. A. J. Cook gives the following on feeding and preparing bees for winter, in the *Rural New Yorker* of last week:

The bees should now be prepared at once for winter. If not already done, we should see to it at once that every colony has at least 30 lbs. of capped stores. If to secure this we need to feed, it is just as well to feed granulated sugar syrup as to feed honey. If feeding is necessary, let it be done at once, so that the bees may get it capped over before it is too cold to do it. I have found by actual experiment that bees do better when the pollen is mostly excluded from the hives, and so would advise that frames containing much pollen be left out of the hive. They will be very valuable if returned when breeding commences next spring.

Let all see, too, that only as many frames are left in the hive as the bees will cover. Use a division-board, or two division-boards, so as to make the chamber for the bees only large enough to contain these frames. All these frames should be covered by a piece of factory cloth, and this by an ample sack of chaff or dry sawdust, which may come well down over the division-boards. It may be thought that repetition in these matters is the order of the day; but it is called for, as neglect in these points is the rock on which many—and some of them our ablest bee-keepers—split.

In working with our bees at this season, after gathering is over, we can hardly fail to observe two things—first, the propensity of the bees to rob; and secondly, the even greater tendency to sting. To prevent robbing, we should handle the bees no more than is absolutely necessary; we should leave no honey where they can get at it, and if we see that any colony is being robbed, we should close the entrance so that only one or two bees can pass at a time. The last precaution is also wise, as during the cold nights of October less heat will escape.

Newspapers in America.

For seven years past Edwin Alden & Bro., Cincinnati, Ohio, have issued annually their *American Newspaper Catalogue*, but never duplicated it.

To secure accuracy and reliability they have corresponded directly and through agents with every accessible Editor, Publisher and Post-master in the United States and Canadas.

The number of newspapers and magazines published in the United States and the Canadas as herein catalogued is 13,273 (an increase over the number last year of 1,115). Total, in the United States, 12,607; in the Canadas, 666.

CORRESPONDENCE

For the American Bee Journal.

Sending Queens by Mail.

G. M. DOOLITTLE.

Having had considerable experience this season in sending queens by mail, as I have sent out several hundred without loss (with a single exception, and that being chargeable to an accident occurring before the queen left my place), I thought perhaps the readers of the BEE JOURNAL might be interested in a description of the cages used, and the mode of making the food for the bees during the journey.

The cage is a block of soft wood, either pine or basswood, three inches long by two wide by $1\frac{1}{4}$ thick; 5-16 of an inch from one end is bored a $\frac{3}{4}$ inch hole, going nearly through the block the 2-inch way, and 5-16 of an inch from the other end is bored a $1\frac{1}{2}$ inch hole, going nearly through the block the $1\frac{1}{4}$ way, which brings the two holes within 1-16 of an inch of each other. By having the holes run through the block from two different sides, the block has more strength than it otherwise would, and it also gives room for nearly double the feed in the $\frac{3}{4}$ inch hole, which could be got in a hole running the same way as the $1\frac{1}{2}$ inch hole does.

Into the $\frac{3}{4}$ inch hole is poured melted beeswax, so as to coat the wood with wax, and thus prevent the moisture being absorbed from the candy. After being waxed, a $\frac{3}{8}$ inch hole is cut so as to join the two auger holes, for a passage-way for the bees to their food, which is to be placed in the $\frac{3}{4}$ inch hole. After the food is in the hole, a cork made of pine $\frac{3}{4}$ inch in diameter by $\frac{1}{8}$ thick, and by a punch which can be purchased at any gun store, is driven in, after being previously dipped in melted wax. Thus we have, as it were, a miniature barrel, full of food, and the bees are admitted thereto through the bung hole. The wax-coating allows no moisture to escape, and the form of the hole and the way the bees are admitted, keeps the food in place, so that it cannot possibly get loose and kill the bees. Over the $1\frac{1}{2}$ inch hole is placed a $1\frac{7}{8}$ inch square piece of wire cloth, which is nailed down after the queen and bees are in. Next, a piece of a section honey box, 3 inches long, by 2 wide, by 3-16 thick (having for ventilation a $\frac{3}{8}$ inch hole bored in it so as to come directly over the $1\frac{1}{2}$ inch hole), is nailed over the side of the block having the wire cloth on it, and we have our cage completed.

The candy is very easily made, and will keep moist and in good condition in the above described cage, for a year at least. Take about 2 lbs. of pulverized sugar, which can be obtained at any grocery store, and put it into an ordinary tin pan; make a little hollow in the sugar and put therein 3 tablespoonfuls of good, clover or basswood

honey. Now mix with the spoon till it gets quite thick, when the spoon is laid aside and the batter is kneaded, as a woman would knead dough for bread. This kneading is kept up till you can roll the candy in your hands, as boys roll snowballs. When it is so hard that it will retain its round shape when placed on a flat surface, except to flatten somewhat on the underside, it is ready for use.

To put it in the hole in the cage, get a stick $\frac{5}{8}$ in diameter, and pound it in (keeping your finger over the feed hole), till the barrel is full, lacking $\frac{1}{8}$ inch. Now drive in your waxed pine cork, and you have it secure. In driving in the cork, I generally use a clamp on the cage to prevent the splitting of it, as the wax on the cork and that on the hole makes it go in rather snug, as it should do.

With this food and the cages above described, I have sent queens safely to Texas, California and Oregon, as well as to nearly all the other states in the United States. The postage required is but 2 cents.

Sometime last February, Mr. Cameron, of Scotland, wrote me to send him one of my best queens by mail, if I was willing to try the experiment, sometime during the summer. I replied that I would do so, although I had little faith that I could get a queen to him by mail alive. Accordingly, on Aug. 1, I made a cage twice as long as the one described above, of a block 2 inches square. Instead of using a $\frac{3}{4}$ inch feed hole as in the above cage, I used two 1 inch in diameter (one at each end) and bored two $1\frac{1}{2}$ inch holes in the center so they cut together, which gave a larger bee apartment. This cage gave room for nearly four times as much candy as the other, so I placed with the queen 25 worker bees as attendants, instead of 10, as I usually do in the other cages.

The bees and queen were placed in the cage at 11 a. m., Aug. 1, and the cage placed, wire cloth down, on two $\frac{1}{8}$ strips, being thus left till the next morning, so that the queen could rid herself of eggs, and the workers clean out the cage of anything therein which they may dislike.

In selecting bees to send with a queen, I take those as near to 6 or 8 days old as I can, and catch them as they are filling themselves with honey, waiting till they have their honey sacs nearly full. Having tried bees of various ages together with those which have not filled themselves with honey, I find that such bees give the best result.

But to return: At 6 a. m., Aug. 2, I nailed the cover over the face of the cage, wrapped it up in strong manilla paper, except the two $\frac{3}{8}$ holes (one over each of the $1\frac{1}{2}$ inch holes), tied it up with good strong twine, and tied thereto a tag bearing the address. As queens are not supposed to go in the foreign mails, I took the precaution to register the package, so as to be sure it should be forwarded after it left the confines of the U. S. At 7 a. m. her majesty started for her home in the old world. On the evening of Sept. 4, I received the following letter:

BLAIR ATHOLE, SCOTLAND, Aug. 18, 1883.—"You have done it, my friend; you have done it! Shortly after 8, on the morning of the 16th inst., I received the package containing the queen bee. You may be sure I very quickly peered inside, and as quickly had the satisfaction of seeing probably the first live queen that ever crossed the Atlantic. I delayed as little as possible before I opened the cage or royal palace, for such it seemed to be—clean, sweet, and in perfect order. On opening, I found the queen in splendid trim, and so was her attendant bees. Two only of the bees were dead. The candy was not half eaten, and it had kept its place in the cage. No spots of dysentery; in short, everything was first-class. This morning, while I held the frame in my hand, I saw her deposit eggs. Success to her. With kindest regards and many thanks for sending her majesty, I am yours, etc.,

ANGUS CAMERON."

I have given the above with the hope that the plan may be so improved upon, and our postal laws so arranged, that the time will not be far distant when we can receive queens from Italy through the mails, and thus save the heavy expense now attending the importation of queens from that and other foreign countries. I firmly believe that queens can be so put up that they will stand a month's journey in the mails, and perhaps longer.

For 3 years past I have sent many queens to Canada by mail, and since the first year I have had no more trouble with their going safely, than in the U. S. I see by a late BEE JOURNAL that the Superintendent of the Foreign Mails gives notice that it is not lawful to send queens by mail to Canada. This could have been known by any person having access to the Postal Guide, without appealing to the Superintendent. The Postal Guide distinctly states that *samples* only of merchandise are mailed at 10 cents postage for every 8 oz., or less; hence the sending of merchandise of every kind to Canada, by mail, is illegal.

However, all are aware that *custom* often has more weight upon the minds of the people than does certain laws. For instance, we have a law against working on the Sabbath, yet how many go into the field, and labor regardless of the law. So of our laws against adulteration, we can say to our sorrow that customs are stronger than the law. In the time of slavery, custom said the law allowing the master to capture the slave, when he had escaped, was not a righteous law, and many a bold man helped the slave to escape. So it seems to have become a custom with the most of the postmasters in the United States and Canada to look upon queens as mailable between the two countries.

The first year I mailed queens to Canada, I lost several by their being held by postmasters in Canada. Finally, Mr. Williams, of Nixon, Ont., wrote me if I would put on the cage, "Queen bee for the improvement of stock," that there would be no trouble regarding their safe delivery. Since

then I have done as he advised, and have not lost a queen in a single instance; although this was evidence plain to every postmaster that the package contained merchandise instead of samples. I have always, however, stamped every package with 10 cents worth of stamps, although most of our Canadian friends forget to add that to the price of the queen.

As the queen traffic is assuming large proportions between the two countries, I would suggest that a better way than the above would be for some of the bee-keepers of either country having influence with the Postoffice departments to see if a law cannot be obtained allowing queens to pass in the mails between the two countries, thereby avoiding the "very appearance of evil."

For the American Bee Journal.

Kentucky Bee-Keepers' Convention.

The Kentucky bee-keepers met in convention Aug. 29, at Louisville, Ky. The meeting was called to order by President Demaree. Calling the roll and reading the minutes of the last meeting were dispensed with.

President Demaree, Chairman of Committee on "Fertilization and queens in confinement," reported that nothing had been accomplished, and, on motion, report was received and committee discharged.

The following new members were enrolled: J. L. Smith, Horse Cave, Ky.; Wm. C. Pelham, Maysville; J. L. Wilson, Martinsville; Dr. W. M. Rogers, Shelbyville; C. H. Dean, Jett; C. W. Buck, Midway; W. L. Stewart, Eminence; J. T. Conly, Napoleon; L. P. Moberly, Hardin County; John Craycraft, Smith's Grove; W. P. Gibson, Sherman; C. D. Mizze, Cleveland, Fayette County; R. A. Barlow, Richmond; W. S. Vandyke, Orr, Anderson County; G. W. Jenkins, New Liberty; G. W. Ashley, Valley Station.

On motion the following persons present from other States were made honorary members: W. S. Hart, New Smyrna, Fla.; C. F. Muth, Cincinnati; W. E. Preston, Iowa City, Iowa; R. Grindel, Baden, Mo.; W. C. Henly, Knoxville, Tenn.; W. C. Kemp, Indiana; H. C. White, Madison, Ind.; Miss Emma Sharpe, Waverly, Ind.; J. Sharpe, Waverly, Ind.; C. B. Merkin, Eddyville, Ind.; W. Cheney, Eddyville, Ind.; Mrs. Aug. Knoefel, New Albany, Ind.; E. Rockenback, New Albany, Ind.; Master Fred Craycraft, Salem, Ind.; Mrs. E. Rockenback, New Albany, Ind.

Reports from members and visitors were called for.

Allen & Craycraft, 56 colonies in the spring; 40 were run for comb honey and gave 3,000 lbs. in one and two-pound sections; 10 were run for extracted, and stored 1,200 lbs.; about 1,000 comb yet to be taken; increase 26 colonies.

W. Cook, 26 colonies, 1,200 lbs. comb honey; increase 31 colonies.

G. W. Ashley, 36 colonies; 2,000 lbs. comb honey; 600 lbs. extracted; 34 increase.

J. L. Smith, 6 colonies; 450 lbs. of comb honey; no increase.

W. H. Howlett, 75 colonies; comb honey, 500 lbs.; extracted, 7,000 lbs.; 320 lbs. largest yield from one colony; increase, 55 colonies.

Dr. A. W. Kaye; 5 colonies; 500 lbs. comb honey; increase 11.

Dr. L. E. Brown, 14 colonies; 1,000 lbs. comb honey; increase 36 colonies.

J. T. Wilson, 80 colonies devoted to queen rearing; had sold \$1,007 worth; 800 lbs. honey.

W. C. Pelham, 65 colonies; 12,000 lbs. extracted honey.

C. H. Dean, 12 colonies; 1,400 lbs. honey; increase 32 colonies.

S. W. Buck, 21 colonies; 2,406 lbs. honey; increase 14.

J. F. Conly, 75 colonies; 500 lbs. comb honey and 5,500 extracted honey; increase 55; sold \$800 worth of honey.

W. C. Cunningham, 31 colonies; comb, 200 lbs.; extracted, 4,000 lbs.

W. L. Stewart, 60 colonies; 4,000 lbs. comb honey; 650 lbs. extracted; increase 66 colonies.

L. P. Moberly, 53 colonies; 1,800 lbs. comb, 200 lbs. extracted honey; increase 29.

Rev. L. Johnson, 42 colonies; comb 500 lbs.; extracted 500 lbs.; increase 40.

G. W. Demaree, 49 colonies; 4,000 lbs. comb and extracted honey; increase 39; 6 colonies gave 600 lbs. of extracted honey.

Report of Visiting Bee-Keepers.—W. S. Hart, New Smyrna, Fla., 76 colonies; 10,000 lbs. extracted honey; increase 88; said his neighbor had 176 colonies; increase 200 colonies; took 18,000 lbs. extracted and 500 lbs. comb honey; said the black mangrove was the best honey-producing flower they had; said palmetto gave large yields of honey in May; swarming commenced in February, and the best honey flow was in May; they shipped honey to Boston, New York and Cincinnati; the native bees were large, brown bees, very gentle and easy to handle; the average profit was \$15 to \$20 to the colony.

W. C. Henly, Knoxville, Tenn., reported large crops of honey in that State. Mr. Kemp, Orleans, Ind., 17 colonies; 1,200 lbs. of comb honey, 300 lbs. extracted; increase 6; W. C. Preston, Iowa City, Iowa, 37 colonies; 2,000 pounds of extracted honey.

On motion the following committee were appointed to report questions for discussion at afternoon session: Dr. Wm. M. Rogers, W. T. Stewart and J. Craycraft.

President Demaree then delivered his annual address, which was well received.

On motion of Dr. Brown, the convention adjourned til 2 p. m.

EVENING SESSION.

The convention was called to order at 2 p. m. Committee on questions for discussion reported the following:

1. Spring management of bees.
2. Methods of preventing natural swarming.
3. The character and practical uses of comb foundation.
4. What are the best and cheapest packages for marketing honey in bulk?
5. Can benefit be derived from the new races of bees?

On motion, report of committee received and committee discharged.

On motion the election of officers for the ensuing year was held with result as follows: G. W. Demaree, President; J. Craycraft, Vice-President; N. P. Allen, Secretary; I. B. Nail, Treasurer.

Vice-Presidents.—E. Drane, Shelby county; J. L. Smith, Hart county; Wm. Cook, Warren county; G. W. Ashley, Jefferson county.

The convention then discussed the following questions:

1. Spring management of bees, discussed by C. H. Dean, C. F. Muth, G. W. Demaree, W. C. Preston, and C. W. Buck.

2. Methods of preventing natural swarming, discussed by G. W. Demaree, C. F. Muth, and N. P. Allen.

Conclusion.—That swarming could be prevented by giving the queen plenty of room to deposit eggs, and the workers plenty of room to deposit honey. Mr. Dean gave his method of preventing swarming.

Mr. Cook said he pinched off the head of the queen, and returned the swarms, and gave them a good smoking.

3. The character and practical use of comb foundation. W. C. Pelham said 5 feet to the pound was most desirable for brood comb.

President Demaree said bees did not build on the wall of the cell, but drew it out, and that the cells ought not to be so deep that the bees could not reach the bottom, as the base of the cell would be too thick.

Mr. Muth illustrated how to arrange wire in foundation, and said it should not touch ends or bottoms of frames by $\frac{1}{2}$ inch.

Dr. Kaye said, when foundation sagged and was crooked, he put a board on the comb, pressing it down level with frame, first cutting foundation loose from frame, and always got straight comb.

G. W. Demaree and M. Buck had tried it, but did not like it.

Dr. Allen said foundation should be absolutely pure beeswax with no mixture of paraffine or other wax.

Mr. Pelham cautioned bee-keepers against using paraffine in the smallest quantity in beeswax for foundation.

Adjourned to meet at 7 p. m.

EVENING SESSION.

What are the cheapest and best packages for marketing extracted honey in bulk?

Mr. Muth said, he preferred cypress, or any soft wood for barrels; preferred barrels and half-barrels, or smaller; said 90 out of 100 oak barrels would leak; can afford to pay more for soft wood barrels; can buy cypress barrels in flat for \$1.65 at the factory; said he desired four wire nails in the bungs to secure them from being removed; in small packages, sells one pound better than two pounds; is not in favor of fancy or gaudy labels for cans or buckets. Mr. Hart prefers 40 gallon barrels, soft wood.

Dr. Allen said, oak barrels, no matter how well seasoned, would shrink after being filled with honey, and the hoops should be driven up from time to time.

Can benefit be derived from the new races of bees? Dr. Allen said, he did not think we were benefitted so far by the new races.

G. W. Demaree said, he doubted if there was a pure race of bees in the world, and could not see at present that we were benefitted by the new races introduced, but thought the time might come when a more valuable race would be developed.

On motion, the President appointed the following committee to prepare questions for discussion at the next annual meeting: C. H. Dean, Wm. Cook and W. T. Stewart.

Adjourned to meet at 9 a. m.

Aug. 30.—Convention met at 9 a. m.

The following committee was appointed to collect information as to the conditions of bee-culture in Kentucky, and to the adaptability of the State to honey-production, giving the sources from which honey is gathered in the State in different localities: N. P. Allen, W. C. Pelham, and J. L. Conley.

The committee to draw upon the treasury of the society for stationery and printing circulars.

On resolutions: Dr. Kaye, J. T. Conley, and J. T. Wilson.

On exhibits: C. F. Muth, W. S. Hart, and A. C. Cunningham.

On motion, it was decided when this convention adjourns it should adjourn to meet at Eminence, Ky., the time to be fixed by the executive committee.

Resolutions were passed by the committee and thanking the managers of the Exposition for courtesies and the liberal premiums; the press, for notices; and requesting the papers of the State to publish the proceedings.

The committee on exhibits of honey and bee-keepers' utensils reported about 20 exhibits, which made a very attractive show.

N. P. ALLEN, Sec.

Pasturage for Bees.

A. R. KOHNKE.

Having experimented quite extensively with honey-producing plants this summer, I will contribute my mite toward improving bee pasturage.

I must join with Mr. J. F. Plummer in pronouncing borage the plant *par excellence*. Bees will leave everything else if they have that. The honey is as light as white clover honey, but of better taste and flavor. Next year I intend to sow several acres with this plant. If sown three weeks before white clover comes into bloom, it will be at its best when that plant begins to fail. I sowed some as late as July 1, after which a drought set in, in consequence of which it was very slow in coming up. But it is blooming now, and the heavy frosts we have had this month have not injured it in the least; the bees improving every shining hour on it, especially the Italians. The latter will be out working even when quite cool; the blacks would not.

On mignonette they worked very little; last year, not at all. Last year, and the year before, I sowed some sweet clover, but it never came up; but I have seen the roadsides in Virginia covered with it, but no bees working on it, though there was no other plant in bloom, except, perhaps, red clover, which is very extensively cultivated; but no bees did I see on that either.

Then I received also some 20 different kinds of seeds from Switzerland, among which were a few kernels of the giant balsam (not giant lady slipper, as some one wants to have it, as it is not related to the lady slipper family or species). I am sorry to say, the seed did not come up, as also many other kinds did not make their appearance. Some proved to be biennials, not flowering the first year; among those which bloomed, phacelia was visited the most. All the others the bees treated with indifference.

But one other thing, I have noticed that bee-pasturage improves where bees are kept; perhaps on account of a more extensive fertilization of the plants by bees, causing a more abundant seeding.

Youngstown, Ohio.

For the American Bee Journal.

Doubling up for Winter.

MRS. E. H. MASON.

As this is the season for doubling-up colonies, I will give my method, for the benefit of the bees, as it prevents fighting:

Take a canvas or honey cloth a little larger than will cover the frames; cut out a piece in the center 4 or 5 inches square, take a piece of wire net, place it over the opening and wax it down good and strong around the edges, then cut another opening in the side of the honey cloth an inch square; lay over that a strip of canvas, leaving the end long enough to hang on the outside of and between the hive and top box; wax that slightly over the inch opening, yet so that it can be readily drawn off; take your new cloth and go to the hive that you wish to give the swarm to, lift out a frame of brood with eggs and larva, brush the adhering bees back into the hive, spread on your prepared cloth, lay on the cushion and cover up till needed, then take an open box or hive, that will fit snugly to your prepared hive; hang in your frame of brood, carry it to the hive you wish to break up, lift that to one side, or a few feet away, set your box on the same honey board, and cover with a thick cloth; lift out a frame of bees and roll the cloth back, and brush them into the box and cover up quickly, to keep out robbers. The rest of the frames may be brushed off in front on the alighting board, leading to the entrance, which must be contracted to keep strangers from running in. Always have your honey box close by you so as to hang the honey frames in, and cover the canvas down closely as fast as you hang the honey in, that the odor may not escape and attract robbers. Pick

up the old hive and jar or brush the adhering bees in front of the box, and carry the old hive quickly away—put away the honey box, sprinkle a few tansy leaves in front of the box, and set up a shingle in front and leave them until in the cool of the evening, then take the top and cushion off of the bee hive, lift your box of bees as gently as possible from the honey board, and carry them steadily to the hive and set them close down to the honey cloth. If the hives do not fit closely, wind a strip of cloth two or three times around the crevice, or cork it up. Let them stand that way for two or three days, so that they will forget the old stand, then slide out the strip of cloth from the inch opening, in the dusk of the evening, and leave the bees to mix themselves. At any time after a day or so, lift off the box, take out the frame of adhering bees and set it back into the hive where it belongs; spread on a tight honey cloth and cushion, and cover up for winter. Shake the rest of the bees that adhere to the box in front of the hive. Those who will try this method will find their colonies doubled up "just too lovely for anything." I have not told you how I catch and cage the queen, for I never double up a swarm that has a queen.

My bees have done splendidly. I have 83 colonies, all strong and healthy, fine workers, gentle and good natured. I have attended and managed all these bees entirely alone, and by myself.

Vincennes, Ind.

Bees & Honey at Western, Ont., Fair.

W. H. WESTON.

The exhibition of honey in connection with our Western Fair, which has just been held here, was remarkably good this year, being the largest ever shown in this city, amounting to about 10,000 pounds, in all shapes and sizes, from the half-pound section of comb and the 5 cent can of extracted, to the large crate of one-pound sections ready for shipment, and the largest size can of extracted, for the same purpose.

I will just give a short account of the exhibits as they appeared in the hall appointed for the display of this healthful and toothsome article of food.

Mr. Jos. Aches makes a very good show of honey, both comb and extracted; also a cage of Holy Lands, which were admired by the many visitors who were anxious to know more about bees.

Dr. Nugent shows the largest amount of honey in the building, and makes quite a display. He says that he has taken 10,000 pounds from 150 colonies, most of which was extracted.

We now come to the most tasty display of both comb and extracted honey in the Fair, and if there had been a prize, I have no doubt Mr. David Chalmers, of Musselburg, Ont., would have taken it. He had bee books, knives, smokers, etc., all of

which he had for sale, and to all appearances had quite a trade.

Mr. John Rudd, of this city, made quite a nice display, as did also Mr. H. H. Smith, of this county, and one or more others.

I might just remark that considering the amount of money given in prizes, the bee-keepers of this section have done extra well this year; the total amount given in prizes is \$11. The directors still stick to the prize list, which they adopted eleven years ago, but which will be considerably larger next year I hope.

London, Ont., Oct. 5, 1883.

For the American Bee Journal.

Bee & Honey Show at St. Joseph, Mo.

The display of bees and the various products and appliances of the apiary at the Inter State Exposition, which has just closed, has been a most satisfactory one, and shows that the interest in bee-culture is fast gaining ground in this part of the West. The display at last year's Exposition was very encouraging, and the impetus given to this industry by the interest manifested then, showed itself plainly this fall. The exhibit was fully 300 per cent. better than it has ever been before, and that is saying a great deal. It is beginning to be plainly seen that as a honey-producing country, this has many advantages, and apiaries are scattered here and there in close proximity.

Our Exposition manager, President N. R. W. Hartwig, and Secretary C. F. Ernst, are deserving of great praise for the very liberal and excellent arrangements offered exhibitors to display every thing pertaining to "bees and honey" to the very best advantage. They evidently appreciate the growing interest in this valuable industry is developing throughout our entire country.

The apian department was under the charge of Mr. D. G. Parker, who acted as superintendent, and was to be found at his post night and day. He resides about seven miles south of this city, where he has 80 colonies of bees, and is provided with all the modern apiary appliances. He has made the subject of bee-culture a study for more than eight years, and while well-versed in the art, is an enthusiastic admirer of fine bees and honey. He also has quite a large class of amateur bee-keepers that are progressing finely under his teachings. Mr. Parker had several colonies of bees, also a large amount of magnificent honey on exhibition, but being superintendent of the department, did not make any entries. The exhibition embraced nearly 3,000 lbs. of honey and 20 colonies of bees, also queens in wire cage, nuclei in observatory hive, in which the bees could be plainly seen at work about the comb. These are all familiar to bee-keepers, but to those not initiated in the art, they call forth expressions of great surprise and delight, and show that the spirit of progress is abroad in the land.

Among the prominent exhibitors, were Mr. J. L. Smith, Lawson, Mo.; Mr. Ernst Shuman, Breckenridge, Mo.; Miss Pateet, St. Joseph, Mo.; Mr. J. B. Stanchiff, Brookfield, Mo.; Mr. J. Madinges, St. Joseph, Mo.; Mrs. Roy, King Hill, Mo.; Mr. D. A. Pike, Smithburg, Md.; Mr. H. Scoville, Columbus, Kans.; Mr. E. F. Gordon, St. Joseph, Mo. Mr. Scoville's exhibit was a very interesting one, consisting of a bee library and apiary appliances of every description used in modern bee keeping, including 30 varieties of seeds of honey-producing plants, also sample copies of 18 bee periodicals from all parts of the world. Large crowds visited this department during the entire week, and Mr. Parker was indefatigable in explaining everything to the spectators.

The premiums were awarded as follows: Best display of bee-keepers' tools, implements and fixtures, best bee feeder, best honey knife, best bee smoker, best comb foundation, best bee veil, wax extractor, largest assortment of honey-producing plants, and best display of Italian queen bees, to Scoville & Anderson.

Best and largest display of honey in comb, E. Shuman, Breckenridge Mo., 2d premium, J. B. Stanchiff, Brookfield, Mo.

Best and largest display of extracted honey, J. L. Smith, Lawson, Mo.

Best colony of bees in hive, including handling and subjugation, E. F. Gordon, St. Joseph, Mo.

Best foundation machine, Ernst Shuman, Breckenridge, Mo.

Best honey extractor, also best display of honey, Miss Pateet, St. Joseph, Mo.

Best and largest display of comb honey, J. L. Smith, of Lawson, Mo.

Best display of Italian bees, E. Shuman, Breckenridge, Mo.

The brilliant success of this exhibition will undoubtedly add many new recruits to this pleasant, interesting and profitable industry. II.
St. Joseph, Mo., Sept. 29, 1883.

For the American Bee Journal.

Section Racks Again.

* T. E. TURNER.

It is a little out of season for an article upon surplus arrangements, as the season for surplus honey in most localities has closed, but my surplus time was all occupied looking after bees, honey, and other things, when an article on section racks would have been most appropriate. But it is never too late to do a good act.

I have no ax to grind, and I trust your readers will bear in mind that I am not a supply manufacturer and dealer, and have no personal interest in any particular rack, but that I have an interest in whatever will be for the advancement of apiculture.

Inquiries have been made in the BEE JOURNAL of Mr. Heddon, about his rack, how he gets the sections out of it, and how he can tell when they are full? Now, if we look at it,

a rectangular box, the right size to hold a certain number of sections, with a bottom board to place on top of the hive with $\frac{3}{8}$ inch space under it over the brood frames, and the same space on top under the sections, we will not think it strange that the ordinary bee-keeper should ask such questions.

Some years ago I was ready to ask the same questions of a Wisconsin apiarist, manufacturer and dealer in bee-keepers' supplies, about a similar rack, but the portable-sided rack with glass views put a stop to such inquiries.

An ingenious fellow can master the situation and meet the necessities of the case by a process of underpinning the racks inverted, and knocking the sections down and out, but others set about to improve the rack itself with portable sides, so the sections could be removed with ease without any knocking and jarring, and with glass in the sides so the sections could be seen when full without removing the honey board.

Now, I need not ask any one how to remove the sections and how to tell when they are full; but can look through the glass and see into the sections without disturbing the bees, and take away the racks from three or four sets of sections per minute, if desired, and leave them on the table ready for casing. This is three or four times as fast as Mr. Heddon claims he can remove them from his rack by the most ingenious underpinning and knocking down process. Then his rack certainly has too much space between the bottom of the sections and the brood-chamber, $\frac{3}{8}$ inch under the honey board, and $\frac{3}{8}$ inch above it, and $1\frac{1}{2}$ inch for it (honey board), will make $1\frac{1}{4}$ inches between. It is universally admitted that the nearer the sections are to the brood-chamber, the quicker the bees will occupy them, and hence the more honey they will put in them.

Then in tiering up there is $\frac{3}{8}$ inch between each set of sections when there should be none at all. The racks should be no deeper than the sections, $1\frac{1}{4}$ inches, and then one tier will set right on another, leaving no space between tiers, and but $\frac{3}{8}$ inch space over the brood frames under the honey board.

The sections should stand on a honey board with slats the same distance apart as the bee-passages between them, which will protect them from propolis and any waxing in the top or bottom. Experience has taught that bees will wax the bottom and tops of sections more or less when they are exposed, and I believe be-nature under the same conditions is the same the world over. This would be a great improvement in the way of keeping the sections clean, and would be far in advance of the old broad frame system.

The broad frames for holding sections with its inconveniences is fast giving place to the new racks, just as fast as bee-keepers are becoming enlightened in the best modes of holding sections in place on top of the hive. The stationery-sided rack with-

out glass is inconvenient if only a part of the sections are full and to be removed, for a whole tier must be taken out to get one full section out, or run the risk of breaking the capping in shoving it by another one.

The portable-sided rack has all the advantages of tiering up and of removing sections by the rack, instead of one at a time, that the stationery-sided rack has; and then it has the advantage of removing a part of the surplus honey, one or more sections, without disturbing the others, if desired, in case of a shortening up of the honey flow, or danger of coloring up of the combs. Separators can be used in the one as well as the other, but I regard them as worse than useless in either. The glass to view the sections to tell when they are ready to remove from the hive, I regard as a very convenient arrangement, but the rack may be made either with or without glass, to suit the taste, in that respect; but the portable-sides in a rack I regard as very necessary and important. The portable-sided rack certainly has *all the advantages* of any other kind of a rack, and *none* of their *disadvantages* as far as my knowledge extends on section holders.

My Fourth Annual Report.

EUGENE SECOR.

I belong to the amateur list. I keep bees because I like to; in fact, because I cannot help it, and not merely for the dollars and cents it brings me. I belong to that number who believe in occupying their leisure moments in a profitable industry, rather than with fast horses, dog and gun, billiards or base ball. Hence I have drifted into those delightful employments of cultivating fruits and keeping bees as a recreation, and as a means of furnishing the family those luxuries which money cannot always buy in the markets of a small inland town. My love for the fascinating art, made practical by the immortal Langstroth, increases with my years, and some day I may make it my specialty.

The past four years have been exceptional in many respects. A great deal of cool and wet weather during the summers, and at least two very trying winters, have militated against the highest achievements in the apiary. The season just closed has been very cool. There has been frost about every month, and only a short time when the nights were warm enough for the bees to venture far from the brood nest; comb-building in surplus boxes was, therefore, slow. Frost came and killed the flowers about two weeks earlier than usual, and cut short the best honey flow of the season. White clover bloomed freely, but gave hardly any surplus. Basswood appeared to be plentiful and full of nectar, but as it rained nearly all the time it was in bloom, we obtained no honey from it. Sumac has again this year proved to be one of the best honey plants among our mid-

summer blossoms. Some section boxes filled with this kind of honey, present a wonderfully clear and beautiful appearance. The fall flowers were plentiful and yielded generously until the freeze, Sept. 8.

I began the season with 14 colonies, all in fine condition except one. They increased by natural swarming to 26. I devoted three colonies and their increase to extracted honey from upper stories, and the remainder to comb honey in 1½ lb. boxes. They began swarming in May and kept at it at intervals till late in August. All but the first swarms were returned. The first surplus removed (box) June 29. I kept a strict account with each colony, as well as every important fact in its history, by means of a card on the top of each hive.

Total number lbs. comb honey, 758; extracted, 450; total, 1,208 lbs. Greatest amount of extracted from one colony and its increase, 151 lbs. Least amount of comb honey from one colony, 23 lbs. Greatest amount of comb honey from one colony, 114½ lbs. Average, comb and extracted, per colony, spring count, \$6 2-7. This is not as well as I expected to do, nor as well as I should have done, had the season been a little more propitious; but, as none of my neighbor bee-keepers have done as well, I ought to feel somewhat reconciled.

I shall never be satisfied until I can make my colonies average a hundred pounds or over, of comb honey. I believe such possibilities are in the business, and if I can only reduce that possibility to a certainty, you may then write me among the happy mortals who "get there."

Forest City, Iowa, Oct. 1, 1883.

For the American Bee Journal.

Drone-Laying Worker Bees.

GUST. MARHARD.

Having noticed some articles in the BEE JOURNAL on drone-laying workers, I thought I would send you my experience with them during the 30 years of my handling bees.

The first case was a strong black colony, which had been deprived of its queen to force them to construct royal cells for use in the apiary. The colony constructed seven fine cells, six of which were taken out and but one left them. The young queen was lost in her bridal excursion, when they were furnished with another royal cell. The queen was again lost. The weather here in Oregon is very changeable, and unfavorable for queen rearing a greater part of the year.

Fresh brood was then given to the colony, as there were no royal cells just then. But the bees had, in the mean time, accepted of a drone-laying worker as queen, and did not construct any royal cells. I then gave them a good laying queen, but found her gone the next day, when I gave up the colony as unredeemable, after I had taken them into a room before closed windows, and had made them all travel, to see if I could not dis-

cover any suspicious looking worker among them, in which I failed.

In the mean time summer has passed, and it happened that a small colony of bees, with a laying queen, which had left its hive in despair, came to settle on an apple tree in my garden, which I hived for to experiment with them on my despaired-of colony, with the drone-laying worker. The colony belonged to a neighbor of mine, who was a real genius of a bee man, a great experimenter, and very neglectful man, who tried to rear queens of drone brood, experimenting with his colonies until he had not a decent colony left, and who either would not shut his hives at all or would cover them but partly. But the bees did belong to another man, and it is not a costly thing to experiment with another man's property in a triling way.

I united the small colony with the afflicted colony, shut the hive up, after smoking them well, and let them alone for an hour. After re-opening the entrance of the hive, about 50 dead workers were pushed out. Next day I found the queen alive, and the colony thenceforth went on all right.

I have had several cases since, and have saved every colony by taking a frame of brood with the queen and bees thereon and setting the same in a new hive. Then remove the hive with the drone-laying worker, and set the new hive in its place. Then take the combs of the affected hive out, shake and brush all the bees therefrom, before the entrance of the new hive, to make them enter. After this is done, either put the emptied combs in the hive also, or exchange them for combs out of another hive, which latter way is by far the better. The bees with the queen on the frame are by no means in a fighting spirit, and the bees of the drone-laying worker colony become dispirited by taking their combs and making them enter a new hive with new combs. The workers on the frame with their queen will defend their queen until better counsels prevail, and the drone-laying worker is dethroned.

The exchange of combs is also the safest way to introduce a new queen in another colony, and it can be done within an hour's time without fear that the bees will destroy her upon introduction, or any time thereafter, when the bee-keeper may wish to open and inspect the hive. If the bees are forced to accept of strange combs and brood, they are just as ready to accept of a strange queen as soon as they have become convinced that the loss of their queen and her brood is irreparable. This will be within an hour's time, at the farthest. I once received from California a Cyprian queen unexpectedly. She arrived late in the afternoon, and I had no colony ready for her reception. I went to a hybrid Italian colony, found and removed their queen, took all their comb containing brood, and exchanged them for others out of another hive. Half an hour later I introduced the Cyprian queen in a black cage with the hole filled with

honey in the comb. I found the queen next day all right on the combs.
Portland, Oregon, Oct. 1, 1883.

Bees and Honey at the Maine Fair.

This is the first time for seven years that a full line of bees, honey and bee implements has been on exhibition at the Maine State Fair, and it was very successful. Mr. Jerrard's exhibit was among the best. By an ingenious contrivance the packages containing a hundred weight or so, are placed upon springs, thus insuring safe transportation with ordinary care in handling. Two colonies of bees from Mr. Jerrard's apiary confined in observation hives, form an interesting exhibit. The farming of this class and awarding premiums for bees and apiarian supplies, is a new feature of the State society, and, as the entries and exhibits in this line shows, struck the bee men in the right spot. The exhibits in this class are quite numerous, and comprise a large collection of hives and fixtures that, to the practical bee man, has much interest.

Mr. E. P. Churchill, of North Auburn, makes a good exhibit of his chaff hives, division boards and bee fixtures. He also makes a good exhibit of honey put up in various tempting forms, a bee tent of simple construction, by which one can manipulate bees to exhibit, transfer, etc., without fear of robbing by predatory bees. His exhibits also comprise a colony of bees in observation hives.

Piscataquis' veteran bee-keeper, Mr. Lucian French, of Sangerville, makes a large and interesting exhibit of tools for the apiary, and honey and wax.

Among the curiosities, was Mr. French's foundation machine, whereby the comb is started for the bees, and taking hold where the machine leaves off, the bees find the labor greatly curtailed in getting the summer stores. Mr. French gave a practical illustration of the working of the machine, showing how sheets of wax were passed through and came out with the cells perfectly formed.

Mr. French makes a tempting display of comb and extracted honey in jars and in 1 lb. sections.

Next to Mr. French's is Mr. Reynold's exhibit. Mr. Reynold lives in Clinton, and handles his bees with great skill. His exhibit shows to fine advantage, his honey being put up in nice shape in one to three pound jars, and nicely labeled; also comb honey in sections temptingly white and nice.

Mr. J. B. Mason, of Mechanic Falls, makes a large exhibit of tools and fixtures used by bee-keepers. Mr. Mason is one of the most intelligent bee-culturists in the State. Among the curiosities of Mr. Mason's exhibit is a collection of bee literature comprising old and modern works. The collection comprises 14 bound volumes and some 20 pamphlets. Another original idea is the life of the bee from the egg to the mature insect, larvae preserved in alcohol in its various stages of growth, comprising 19 periods, that being the daily changes in life in coming to maturity.

Mr. Mason makes a good display of honey put up in various forms. A number of Italian queens are shown in cages, also an observatory hive in which the bees are seen as living in the hives.—*Maine Farmer.*

For the American Bee Journal.

Home Markets for Honey.

DR. J. R. BAKER.

I notice in the BEE JOURNAL that the Editor, Prof. Cook, James Heddon, etc., urge upon bee-keepers to create home markets for honey. At Keithsburg, Ill., where I had the most of my experience as an apiarist, there was an excellent home market established, largely by Mr. Martin Wirt, who, for a number of years, was engaged in scientific apiculture in that locality. I found no trouble to dispose of two and even three thousand pounds of comb honey a year, at from 15 to 20 cents per pound, in the Keithsburg market; and the village only contains about 1,200 inhabitants.

When I came to this city, this spring, broken down in health and purse, I was unable to engage in apiculture at all, but having a brother here who is engaged in the grocery trade, I persuaded him to handle honey. We found a gentleman about 8 miles in the country, who was raising comb honey in good shape, and we engaged to take all he could raise during the season at 17 cents per pound. We made mention in the daily paper of the city, that we had nice comb honey for sale, and people soon called to make purchases; and in a short time we were selling quite fast. Every one who called to see our honey was delighted with its fine appearance. We had it all nicely arranged in a large handsome show case, and had the show case setting on the end of a counter near the entrance door.

After other grocers learned how eagerly people bought our honey at 20 cents a pound, they would hail our honey man whenever he came to the city, and want to buy honey of him; but he told them that they were too late, as he had engaged it all to our house.

Good honey, nicely put up, will sell well anywhere, but the good old-fashioned way of cutting out of the brood-chamber honey, pollen and brood, and casting the whole mess into a pot, jar or pan and taking the stuff to market, was not well calculated to get up a boom in the honey trade.

A farmer brought a dish-pan of this kind of medley to us this summer, and I asked him how much he wanted a pound for it, and his price was the modest sum of 15 cents per pound. I told the vender of much filth and little honey, that I would not take the stuff as a gift, and he went away feeling hurt over my ignorance as a judge of honey. This gentleman told me that he had much better "luck" in log gums than in "patent" hives.

Mr. Heddon was exactly right in his brief article a few weeks since, in

urging honey producers to not sell their honey at a sacrifice. There is no use for apiarists to become alarmed at the prospect or rumor of a big honey crop, and sell at a sacrifice. The better plan, I take it, is to keep cool and be governed by soberness. Last summer, every few days the grocers, who handled the most of my honey, would say to me that honey was so very plentiful that I would have to sell at smaller figures. When I would ask them where they got their information, they were compelled to tell me that some farmer or farmers told them so. I knew that neither the farmers nor the grocers took any bee journal, and had no means of knowing anything about the honey trade or prospects throughout the country.

These scares in the local markets are gotten up through the ignorance of persons who keep a few bees, and who think that if their bees swarm much, and they have a starch box or two filling with honey, that they are doing "splendid." With this magnificent (?) bonanza right under their noses they will make haste to offer the grocers large lots of honey at from 10 to 12 cents a pound, and the grocers in their innocent ignorance hasten to collapse the scientific honey raiser with their ox-load of information.

Last season I was selling honey to a lady for her own use at 20 cents a pound. She told me one day that she had engaged honey of Mr. S. at 15 cents a pound. I asked her how much, and she said any quantity that she might want. I told her that when she got through using Mr. S.'s 15 cent honey to let me know and I would then sell her some for twenty cents per pound.

Time rolled on, and she called on me for honey. I asked her how much she got from Mr. S., "Not a pound," she replied. I told her I knew it just as well before she told me as I did after, and she wanted to know how I knew. "Easy enough," I said, and then I told her that Mr. S. started in the spring with 5 colonies, and that they had swarmed so much that he then had 30 colonies, and in his ignorance he based his large prospects on the number of colonies he possessed; but that all scientific apiarists knew that it was impossible to have such a heavy increase and a large crop of honey the same season. That the bees of Mr. S. had kept themselves so weakened by their excessive swarming, that they could not possibly gather surplus honey.

This case is simply one given to illustrate how silly it is for honey raisers to become alarmed over the ignorant grape-vine rumors about the tremendous honey yield in the country, based on the statements of log-gum, box hive and starch-box bee-keepers.

Do not give your honey away my friends, nor sell it at ruinous prices, for a careful review of the reports of honey raised throughout the country leads me to the conclusion that the crop, this season, is rather light.

Warsaw, Ind., Oct. 3, 1883.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Can Pollen be Utilized?

Can the pollen or "bee bread" so called, which is found in such quantities in combs, at this season of the year, be utilized? I could get a good deal from neighbors who adhere to the old style of "taking up" bees, and thought if it could be used in the early spring, when wanted, it would be worth something. BEGINNER.

ANSWER.—I consider this pollen you mention, of no use to you. If your bees need early stimulating (which we used to think was the case here, but on which we have changed our opinion), I believe it is generally conceded by bee masters, and plainly shown by the actions of the bees, that rye or graham flour, is of much more value than old, natural pollen.

Uniting Colonies in the Fall.

Will Mr. Heddon please answer the following question:

I wish to dispose of a part of my bees, as I think this place is overstocked. The demand is so small, and the prices so low, that I think the honey and the empty combs will be worth more to me than I can get per colony. I want to know if it will be safe to unite the colonies, and thus save the bees, and at the same time reduce my numbers. If so, when is the best time to do it? My colonies are strong, and the hives are well-filled with honey.

J. B. STANCLIFT.

Brookfield, Mo., Sept. 29, 1883.

ANSWER.—My own opinion is, that such uniting will damage you; that the single colony is worth more to go into winter quarters with, than the proposed "doubled-up" ones. Often the results of such doubling, prove less merciful to the bees, than a sponge of chloroform. Where bees are to be destroyed, I advise the following:

"Take up" the colony at that time when they cease to gather more than they consume. About 21 days before that time arrives (as near as you can guess), remove the queen. This stops the breeding and the gathering of pollen to a great extent, thus giving you less bees and bee-bread, and more honey at the time of reducing your numbers.

Some object to the killing of bees, but some of these persons encourage the killing of cows and calves by daily

consuming large proportions of beef and veal.

Laying aside the question of "cruelty to animals," there are many advantages in this "taking-up" plan:

1. By so doing, you raise the standard of your colony rapidly, by destroying the inferior queens.

2. It saves the purchase of many supplies.

3. It tends to prevent opposition in your field and market.

If you reduce your number of colonies to just what you need the following spring, you should be pretty sure of safely carrying that number through the winter.

Did the Bees Have the Dysentery?

I began the season with about 25 colonies; bought a few more and increased to 60. My crop is about 2,500 pounds, mostly comb. From $\frac{2}{3}$ to $\frac{3}{4}$ is smartweed honey; the balance is from the Spanish needle; all is of good quality, and thick; being all gathered in dry weather. No surplus was gathered until the last of August. Will some one please tell me how they extract Spanish needle honey? It is always so thick and tenacious that I cannot remove it clean from the combs. In winter I can almost stack it up without pails or barrels. Smartweed is easily managed in the extractor. I have been holding the entire crop at 15 cents per pound, against a $12\frac{1}{2}$ retail market. Yesterday morning I took some racks and sections into the honey house from hives when it was so cool that no bees were flying, but some adhered to the boxes, and at noon were flying to the door and daubing things like bees having the dysentery. Was it the chill character of the honey, or something else that caused it? I have only the two kinds of honey mixed, to winter on, and pollen is not abundant.

R. C. Aikin.

Shambaugh, Iowa, Oct. 4, 1883.

ANSWER.—The cause of bee dysentery, of which a colored and partially soiled evacuation, may be called among the first conditions, is as yet in dispute. Some of our experienced brethren would pronounce chilled honey the cause. For my own part, I do not see how a liquid can be changed to a solid, especially of the character of the particles contained in this feces, by a sudden "chilling." I do, however, see how a short confinement will cause young pollen-eating bees to void a feces well-filled with particles of partially-digested pollen. While it may prove true that pollen-eating is the cause of dysentery, in every case it may turn out a fact, that under most favorable conditions bees *can* consume bee-bread during confinement, and yet remain

healthy. I rather doubt the last proposition, however. In the case you mention, there is no cause for apprehension, as there is no intestinal inflammation, or at least none that will shorten the life of the workers. This we know by experience.

SELECTIONS FROM OUR LETTER BOX

Mississippi Valley for Bees.

This has been a poor season for bees. We have only $\frac{1}{2}$ of a crop of honey, and very little increase. In the early part of the season it was too cold and windy, and, after July 1, it was so dry that bees could get no nectar from clover. I am thinking of moving down on the Mississippi valley. Do you think that there would be many bees drowned crossing over to the islands to get honey? There is plenty of honey to be gathered there this fall. I send you a plant for name.

J. F. SELLERS.

Reynolds, Ill., Oct. 8, 1883.

[The plant is an aster, and excellent for honey.]

The Mississippi valley yields excellent fall flowers, and some bee-keepers move their bees to the bottom lands, in the fall, to utilize it. If the bees have to fly across the water to pasture, there is danger of loss in high winds, etc., but we think that loss would be trifling.—Ed.]

Report of the Buckhorn Apiary for '83.

I commenced the spring with 83 colonies—have increased to 78 by natural swarming. I have obtained 2,500 lbs. of comb honey, 4,000 lbs. of extracted, and 50 lbs. of wax. The comb honey is all sold in the home market, and averaged 17 cts. per lb., and the extracted at 14 cts., by the help of the pamphlet on "Honey as Food and Medicine." My "boss" colony gave me 300 lbs. of comb and 400 lbs. of extracted honey. This colony gave three swarms, and the first colony swarmed once, making in all five swarms, all in good condition and well supplied for winter. I winter in a bee cellar under my bee house.

F. A. GIBSON.

Racine, Wis., Oct. 5, 1883.

The Results of the Honey Season.

I commenced the season with 12 fair colonies, increased to 65, and have taken 800 pounds of extracted honey. Twelve colonies in the spring, at \$10 per colony, were worth \$120; I paid for 7 queens, foundation, etc., \$65; total, \$185. I have now 65 colonies on hand, with an average of 30 pounds each; at \$6 per colony, these at \$6 each, amount to \$395; 800 pounds of honey at 15 cents per pound, \$120; 10 queens sold at \$1 each, \$10; total,

\$525. This leaves a balance of \$340 in my favor. A good share of the honey has already been sold at 15 cents per pound. I also have several dozen fruit cans on hand as well as 1000 sections and crates for the same. Also 20 pounds of foundation which I do not give myself credit for, which I can use next season. It has been a poor season for honey. It commenced to rain about May 15, and rained 21 days in June, and nearly all the time until July, when the weather turned too dry, and there was no rain for 8 weeks. Frost killed all buckwheat and corn here. S. J. YOUNGMAN.
Cato, Mich., Sept. 28, 1883.

Boneset or Thoroughwort.

It is the first day of October, and the bees are tumbling over one another into the hive, as though they had not laid up winter supplies, and they have not; but a few more days like the last four, with the temperature from 85° to 92° at mid-day, they can feel that they will be able to live high, and even entertain a little. Please name the enclosed weed. The bloom has a delicious aroma, and furnishes a pretty, light honey, but seems to have a curious, if not deadly effect on the bees. While at neighbor Daniels', a couple of days since, we noticed bees dead on the bloom, and under it on the ground; others had fallen off and were crawling away as though over-powered in some way, and others on the bloom too far gone from the effects produced thereby to be able or disposed to sting while handling them. What is just as curious is, that the same bloom apparently has no effect on my bees, they working the day long as lively as crickets. Now, can it be only a temporary imbruing effect it has? or is it poisonous in its effects?

W. T. MADDOX.

Alexandria, La., Oct. 1, 1883.

[The plant is of the *cupatorium* family (boneset or thoroughwort), and is rich with golden nectar. The tea made from it is used as an emetic, and probably that accounts for the temporary weak condition of the bees, especially if they work on it soon after a rain.—ED.]

Bees Gathered Nothing after June.

The season of 1883 has come to a close, and, although, I do not call it a poor one, it is by no means a glowing one, for this part of the State. Bees did little or nothing until June 10, and then the flow, which was very great, lasted only 30 days, and our great expectations were blasted. From July 1 until Aug. 15, there was no honey to be had, and war among the blacks began, and the loss was great. Some of my neighbors, owning black bees, have not received 15 lbs. per colony, spring count; not getting any surplus after the June flow. My bees being all Italians, have done fairly; the average being 100 lbs. per colony, spring count. I say spring count, for the flow stopped with the swarming fever in June. My best

colonies gave 168 lbs. of surplus per colony, and the poorest 40 lbs. I prefer Italian bees and Langstroth hives.

J. G. NORTON.

Macomb, Ill., Oct. 4, 1883.

Poor Season in Texas.

I send an insect I captured in the act of carrying off one of my bees. I have noticed several this season; they pounce on a bee while resting on a shrub, plant or tree, and fly off with it. Please name it in the BEE JOURNAL. This has been a very poor season in this locality; no surplus, except sufficient to winter on. Bee-keeping has cloudy as well as bright sides, but to the experienced bee-keeper a dull season this year indicates a bright one next year. The monthly visits of the BEE JOURNAL are a source of pleasure to me.

And though I am here, on the Texas frontier,

With my bees and my JOURNAL on hand;

I hear from them all, both great and small

Bee-keepers, over the land.

May the sweet honey bee, fill our hearts full of glee.

Our minds with sweet prospects store;

Let bickerings cease, and knowledge increase,

By the aid of the JOURNAL'S lore.

ANNIE SUTCLIFFE.

Weatherford, Texas.

[The insect is the bee killer called *Asilus Missouriensis*, which has often been described in the BEE JOURNAL of late.—ED.]

Not a Good Locality for Bees.

I had 8 colonies of bees to commence in the spring, 5 strong and 3 weak ones. They gave me about 30 lbs. of honey in all, and I made two new swarms from the five strong ones. It took the other three all summer to fix themselves for winter. White clover yielded no honey here; it has not for the last 3 years, at least. I think this is a very poor place for bees. Two of my neighbors that live in the timber, 3 and 4 miles from here, say they got a big crop. I have 10 colonies now to try to winter. That is all the good I can get out of them, and I generally loose one-half before spring.

HUGH WILLIAMS.

Racine, Wis., Oct. 6, 1883.

Another Aster.

Enclosed you will find a stock with flowers, on which the bees are working from morning until night. Please name it.

J. W. STURWOLD.

Hammond, Ind., Oct. 5, 1883.

[It is an aster—its value is shown by the preference of the bees for it.—ED.]

100 Lbs. of Honey to the Colony.

My bees wintered all right. I began the spring with 7 colonies—increased to 18. I have taken 335 lbs. of extracted honey, and 375 lbs. of comb honey. My bees are mostly hybrids. I have one colony of Syrian bees. I do not know how I like them yet. I use the Simplicity hive, holding 10 frames. I use the 1 lb. sections and winter my bees on from 4 to 6 frames, with chaff division boards at the sides, and then set the hives in cases, holding from

one to three hives, and fill all around with chaff. Prepared in this way they will winter with but little loss.

B. W. PECK.

Richmond Centre, O., Oct. 2, 1883.

Unseasonable Weather in Mass.

The weather has been unusual unseasonable for over a month. It caused a loss to me of over 200 queens. I now have 50 fine ones that I will destroy in a few days, as they will not mate this fall. Up to Aug. 1, the weather was splendid for queen rearing; since that date it has been the worst I ever knew.

HENRY ALLEY.

Wenham, Mass., Oct. 6, 1883.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
Monday, 10 a. m., Oct. 15, 1883. }

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—Our prices are 7@9c. for extracted, and 14@16c. for comb honey on arrival.

BEESWAX—Arrivals of beeswax are good at 25@28c., and the demand is fair.

CHAS. F. MUTH.

NEW YORK.

HONEY—White clover and basswood in 1 and 2 lb. sections, 17@21c. Dark and second quality, 14@15c.; extracted white clover in kegs and barrels, 9@10c.; dark, 8c.

BEESWAX—Prime yellow, 27@29c.

H. K. & F. B. THURBER & CO.

CHICAGO.

HONEY—Comb honey has sold freely for the past two weeks, and stocks are at present low. 1 lb. sections of white comb are bringing 18c.; 1½ to 2 lb. sections of same quality, 16@17c.; various sized sections of white comb, 15@16c. Extracted honey from 8@10 cts. per pound, according to body and flavor.

BEESWAX—Yellow, 32@33c.; dark, 25c.; medium, 30c.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—There is a fair jobbing trade. Offerings are not large. Choice quantities command extreme prices. White to extra white comb, 18@20c.; dark to good, 10@13½c.; extracted, choice to extra white, 8@9½c.; dark and candied, 6½@7½c.

BEESWAX—Wholesale, 27@28c.

STEARNS & SMITH, 40 Front Street.

ST. LOUIS.

HONEY—Quiet. Salable at appended figures, but generally held higher. Strained and extracted at 6½@7c.; comb at 14c.

BEESWAX—Ready salable at 25@26c. for prime.

W. T. ANDERSON & CO., 104 N. 3d Street.

CLEVELAND.

HONEY—Comes very slowly and sells as fast as it comes at 18@19c. for best white in 1 lb. sections, and 17@18c. for 2 lb. sections. Second quality is very slow. Extracted usually sells very slowly in our market.

BEESWAX—None in Market.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—We quote our market at 18@20c. for 1 lb. white clover; 18@20c. for 2 lb. white clover. Extracted, 8@10c.

BEESWAX—We have none to quote.

BLAKE & RIPLEY, 57 Chatham Street.

KANSAS CITY, MO.

HONEY—A large part of the local crop in this section has been marketed, though considerable remains yet in the hands of producers. Very little California honey in this market this season, except extracted, which is in fair supply at 10@11c. for choice new, and 8½@10c. for dark or candied. Choice bright comb 2 lb. sections, 18@19c.; 1 lb. sections, 19@20c. Demand is fair for the better grades.

JEROME TWICHELL, 536 Delaware Street.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00, or 1,000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper, shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter, on your label, notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a statement of account every week.

Trial Trip, until Dec. 31.—25 cents.

Wishing to be able to reach several thousands of the old-fashioned bee-men, and by the aid of the BEE JOURNAL to lift them up to higher ground, adopting newer methods and progressive ideas, we make the following very liberal offer: We will send the Weekly BEE JOURNAL till Dec. 31, *on trial, for 25 cents*. In order to pay for getting up Clubs, we will give a copy of Fisher's Grain Tables, or Scribner's Lumber and Log Book, to any one who will send us five trial subscriptions (with \$1.25); for a club of ten we will give a cloth copy of Bees and Honey; for a club of 15, a cloth copy of the 7th edition of Cook's Manual of the Apiary; for a club of 25, we will present both the Manual and Bees and Honey. If any one wants these Books for nothing, here is an excellent opportunity to get them for a little exertion.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey at Fairs, will sell almost a fabulous quantity of it.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Books at Fairs.—Those who make an exhibit at Fairs will find that an assortment of Books and Pamphlets would sell and leave them a profit for handling. We will send such, postage prepaid, at 25 per cent. discount; or if the purchaser pays express charges, we will supply any of our own publications at 40 per cent. discount.

The new two cent rate of postage for letters went into effect on October 1. Three cent postage stamps will now be but little used. For all fractions of a dollar sent to us hereafter we should prefer either *one-cent*, or else five or ten-cent postage stamps, or a Postal Note. Do not send coins in any letter.

Fairs.—To any one exhibiting at Fairs, we will send samples of the BEE JOURNAL and a colored Poster, to aid in getting up a club. The Premiums we offer will pay them for so doing. For a club of 8 subscribers to the Monthly BEE JOURNAL, or 4 Weekly, we will present Dzierzon's Rational Bee-Keeping, price \$2.00.

Weekly Bee Journal,

DEVOTED TO THE INTERESTS OF THE PRODUCERS OF HONEY.

VOL. XIX.

CHICAGO, ILL., OCTOBER 24, 1883.

No. 43.

ESTABLISHED 1861
PUBLISHED WEEKLY
THE AMERICAN
BEE JOURNAL
ESTABLISHED 1861

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

The Northwestern Convention.

The annual re-union of bee-keepers in this city, which has just closed, was one of the most enthusiastic gatherings ever held in America. The presence of the Rev. L. L. Langstroth, the father of American apiculture, made it the more interesting to many who had never before seen that grand intellectual giant. We cannot better express the character of the Convention than to quote the following from the secretary's report of one of the speeches of Mr. Langstroth, when he said: "I believe that this Convention represents the largest number of large, practical and successful honey producers of any Convention that I have ever visited."

The language of all who attended the meeting was: "It is good to be here." There was no stiffness or reserve; no pet theories to propagate, nor personal antagonism to parade—only "a feast of reason and a flow of soul"—which was enjoyable, as well as highly instructive.

When Mr. Langstroth was invited to speak of "the honored dead, he grew eloquent, and for half an hour he paid a tribute of love and esteem to those who were his co-laborers while introducing the movable-frame principle to the American bee-keepers, which will never be forgotten by those who heard him!

The secretary's report of this may be found on page 527. The daily papers of Chicago had reporters present, and the following is what the *Inter-Ocean* of the next morning gave to its readers, on the subject:

Mr. Langstroth made a few remarks on the subject of hives, combs, and

other honey appliances. He said that they gave him too much credit for what he had done for the business. He spoke of other inventors, among them Major Hruschka, who invented the extractor, and what a help he was to the bee-keeper; also of the way he had invented the present movable-comb hive, Oct. 31, 1851.

He referred to the honored dead who had done much for the bee-keepers of this country. Samuel Wagner, founder of the AMERICAN BEE JOURNAL in 1861, had translated several foreign works which proved of vast help to the bee-keepers.

Moses Quinby, of Mohawk, N. Y., who had done so much to instruct and help others.

Adam Grimm, of Jefferson, Wis., who was the great German bee-keeper.

Richard Colvin, of Cleveland, Ohio, a man who had practically demonstrated the advantage of movable frames.

R. C. Otis, of Kenosha, Wis., who had worked hard to demonstrate the success of the movable frame hive.

Mr. Geo. Grimm arose and thanked the Rev. Mr. Langstroth for the eloquent remarks he had made on his (Mr. Grimm's) father.

A rising vote of thanks was extended to the venerable minister. Amid the utmost, feeling the vote was passed unanimously.

President Miller, after putting that vote, attempted to make some remarks, but he was too much overcome by his feelings to do more than to assure Mr. Langstroth, that the proof that bee-keepers were conscious that they "owed him a larger debt of gratitude than they could ever pay," was evidenced by the rising vote of the entire Convention, and the tears which welled up into the eyes of nearly every one present.

Mr. Langstroth thanked the Convention for their manifestation of love and sympathy not only for himself, but also for his co-laborers who had passed away.

The number of members for this year is 97, showing a steady increase, year after year. Quite a number of ladies were present, and appeared to enjoy the meeting as much as the men, and when the time came for adjournment, it was so difficult for bee men to say "Good by," that they con-

sumed a full hour in "social talk" and "parting words."

The next meeting, in October, 1884, will be looked forward to about as a child looks and longs for the holidays; and we have every reason to expect that meeting to be even a greater success than the present one. Chicago is the great centre of the West, and it is exceedingly easy to come to a meeting of this kind from all the surrounding States.

Home Market.—Mr. T. S. Bull seems to know how to sell honey at home. We find the following item in the *Vidette*, at Valparaiso, Ind. It is an excellent way to advertise honey:

Mr. T. S. Bull, the honey man, has put in an elegant glass case filled with honey in Mr. Dillingham's grocery store on Main street. Mr. Bull's honey is a household word in every family in our city, and its excellence is well known. Drop in Dillingham's and look at the case.

In the matter of paging the BEE JOURNAL cover, our readers will notice that we shall be obliged hereafter to page the entire paper through, consecutively. The following item from a Washington despatch will explain it. We have been notified by the Post-Office Department that if we continue to page the cover separately, we shall have to pay four times the amount of postage:

The Post-Office Department insists that periodicals shall be numbered and paged consecutively, and the law is being enforced in this city, all matter not so numbered being classed as third class and charged at the rate of eight cents per pound.

We regret to learn that Mr. E. F. Cassell, of Illinois City, Ill., was recently killed by attempting to get on the cars at Muscatine, Iowa.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Honey Crop of Illinois.

We have received the official Circular No. 104, from the Crop Reports returned to the Department of Agriculture Aug. 1, 1883. From it we learn that the colonies of bees reported for 1881, were 86,633; for 1882 they numbered 131,633. The number of pounds of honey produced in 1881 were 618,947; in 1882, it had increased to 2,791,301, or over four times as much as in 1881, while the number of colonies had not even doubled. We shall look with interest to the official statistics for 1883.

The statistics, by counties, for 1882, are as follows:

COUNTIES.	Number of Colonies.	Pounds of Honey.

Foul Brood Investigations.

Prof. T. J. Burrill, of Champaign, Ill., proposes to make a thorough examination of the subject of foul brood, its cause and cure, and requests us to make the following announcement:

I am prepared to make some such study, and in the first place would like numerous specimens from different apiaries and localities to ascertain whether the same organisms are to be found in all or not. A small piece of the infected comb, together with any information as to the nature and virulence of the disease will be a contribution to the investigation. After finding what is the probable parasite, this must be separated and cultivated in a state of purity, and then try the effect on healthy brood. Doubtless this cannot be fully accomplished before sometime next year, but a beginning may be made now. I wish you would insert a note in the BEE JOURNAL, asking for specimens and information as to the nature and virulence of the disease, to be sent by mail to me at Champaign, Ill. A half dozen or so infected cells will suffice, and any small wood or tin box may be used. I have no bees, hence do not fear the infection. T. J. BURRILL.

By the Canadian Farmer we learn that Mr. G. B. Jones' apiarian supply factory has been entirely burned up. The BEE JOURNAL extends its sympathy.

We regret to learn of the death of Mr. J. Oatman, of Dundee, Ill., which occurred early in this month. He was the senior of the late firm of J. Oatman & Sons, well known to our readers. The sons now carry on the business from which the father retired some time ago.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
Monday, 10 a. m., Oct. 22, 1883. }

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The demand for honey is extremely slow, and our commission houses are too well supplied to expect anything else. Prices rule low. Manufacturers complain of slow business. Extracted honey brings 7@9c, on arrival. I have bought for less. Comb honey in good order, 12@15. BEESWAX—Good yellow beeswax brings 27@28 cts.; offerings few.

CHAS. F. MUTH.

NEW YORK.

HONEY—White clover and basswood in 1 and 2 lb. sections, 17@21c. Dark and second quality, 14@15c.; extracted white clover in kegs and barrels, 9@10c.; dark, 8c. BEESWAX—Prime yellow, 27@28c.

H. K. & F. B. THURBER & CO.

CHICAGO.

HONEY—Comb honey has sold freely for the past two weeks, and stocks are at present low. 1 lb. sections of white comb are bringing 18c.; 1½ to 2 lb. sections of same quality, 16@17c.; various sized sections of white comb, 15@16c. Extracted honey from 8@10 cts. per pound, according to body and flavor.

BEESWAX—Yellow, 32@33c.; dark, 25c.; medium, 30c.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—There is a fair jobbing trade. Offerings are not large. Choice quantities command extreme figures. White to extra white comb, 16@20c.; dark to good, 10@13c.; extracted, choice to extra white, 8@9c.; dark and candied, 6@7½c.

BEESWAX—Wholesale, 27@28c.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Quiet. Salable at appended figures, but generally held higher. Strained and extracted at 6½@7c.; comb at 14c.

BEESWAX—Salable at 27c. for choice.

W. T. ANDERSON & CO., 104 N. 3d Street.

CLEVELAND.

HONEY—Comes very slowly and sells as fast as it comes at 18@19c. for best white in 1 lb. sections, and 17@18c. for 2 lb. sections. Second quality is very slow. Extracted usually sells very slowly in our market.

BEESWAX—None in Market.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—We quote our market at 18@20c. for 1 lb. white clover; 18@20c. for 2 lb. white clover. Extracted, 8@9c.

BEESWAX—We have none to quote.

BLAKE & RIPLEY, 57 Cutham Street.

KANSAS CITY, MO.

HONEY—Market is quite active for choice comb, and readily taken at 17@18c., not much distinction being made between 1 and 2 lb. sections. Dark and irregular shaped combs, 16@18c. Extracted slow and prices hardly sustained. Choice, in bulk, 9@9½c.; dark and dirty, 7@8c.

JEROME TWICHEL, 538 Delaware Street.

Northwestern Bee-Keepers' Society.

The Northwestern Bee-Keepers' Society met at Owsley's Hall, Chicago, Ill., on Wednesday, Oct. 17, at 10 a. m., President C. C. Miller in the Chair.

Secretary T. G. Newman read the minutes of the last meeting, which were approved. He also read the Treasurer's report, which was accepted and approved. On motion, the Rev. L. L. Langstroth, who was present, was made an honorary life member.

The following members then paid their dues:

James Heddon, Dowagiac, Mich.
T. L. Von Dorn, Omaha, Neb.
Dr. J. Oren, La Porte, City, Iowa.
T. S. Bull, Valparaiso, Ind.
H. D. Burrell, Bangor, Mich.
F. Wilcox, Mauston, Wis.
H. O. Morris, Tiskilwa, Ill.
A. S. Haskins, Lawrence, Mich.
Robert Cissna, Hageman, Ind.
C. L. Sweet, Glenwood, Ill.
James Kuhles, Howard, Ill.
E. Whittlesey, Pecatonica, Ill.
W. D. Angell, Odell, Ill.
J. M. Hyne, Stewartsville, Ind.
P. Morningstar, Wakarusa, Ind.
H. W. Lee, Pecatonica, Ill.
F. H. Hannah, Hinsdale, Ill.
H. Newhaus, Burlington, Wis.
G. B. Lewis, Watertown, Wis.
A. B. Miller, Wakarusa, Ind.
B. J. Miller, Nappanee, Ind.
Mark Davis, Lisle, Ill.
E. S. Hovey, Swanton, Iowa.
J. E. Hunter, Wyoming, Iowa.
Xenophon Caverno, Lombard, Ill.
A. Wecherts, Mattison, Ill.
Hugo Volland, Mattison, Ill.
John Hodgson, Jr., Pewaukee, Wis.
F. A. Snell, Milledgeville, Ill.
J. S. Hooton, New Carlisle, Ind.
G. H. Shirley, Richmond, Ill.
D. S. McKinstry, Grant Park, Ill.
T. F. Bingham, Abonia, Mich.
Otis J. Gandy, Churubusco, Ind.
J. Scott, Oelwein, Iowa.
Wm. Burns, Buchanan, Mich.
S. M. Slade, Elgin, Ill.
James Fornerook, Watertown, Wis.
P. E. Marston, Beloit, Wis.
Wm. Camm, Murrayville, Ill.
E. Lucas, Kirkland, Ill.
Chas. Vail, Michigan City, Ind.
T. D. Ward, Lawton, Mich.
Wm. Blake, Buchanan, Mich.
J. Marvin, St. Charles, Ill.
Geo. Thompson, Geneva, Ill.
S. E. Gernon, Waukesha, Wis.
T. G. Newman, Chicago, Ill.
Dr. C. C. Miller, Marengo, Ill.
M. L. Trester, Lincoln, Neb.
E. T. Flanagan, Belleville, Ill.
W. Z. Hutchinson, Rogersville, Mich.
Emil J. Baxter, Nanvoo, Ill.
Capt. J. E. White, Englewood, Ill.
Geo. Bischoff, Burlington, Iowa.
J. S. Harris, Wheeler, Ind.
W. T. F. Petty, Pittsfield, Ill.
W. A. Carmack, Marengo, Ill.
F. W. S. Brawley, Chicago, Ill.

M. M. Baldrige, St. Charles, Ill.
Richard Hyde, Alderly, Wis.
P. J. England, Fancy Prairie, Ill.
John A. Jensen, Channahon, Ill.
A. T. Wright, Kokomo, Ind.
S. N. Black, Clayton, Ill.
A. Wicherts, Mattison, Ill.
R. G. Ardrey, Oakdale, Ill.
R. Johnson, Valparaiso, Ind.
Hugo Volland, Mattison, Ill.
D. Ryther, Somonauk, Ill.
E. F. Seafar, Chesterton, Ind.
Geo. Grimm, Jefferson, Wis.
J. C. Gould, Paw Paw, Mich.
D. G. Webster, Blaine, Ill.
A. H. Sherman, Bethel, Mich.
Frank McNay, Mauston, Wis.
L. H. Scudder, New Boston, Ill.
E. J. Oatman, Dundee, Ill.
L. C. Wemple, Rogers Park, Ill.
J. A. Green, Dayton, Ill.
Dr. J. A. Walker, Mason City, Ill.
P. P. Nelson, Manteno, Ill.
A. W. Kistenbroker, Oak Park, Ill.

LADY MEMBERS.

Mrs. P. J. England, Fancy Prairie, Ill.
Miss M. Hall, Sweet Water, Ill.
Mrs. Dr. Miller, Marengo, Ill.
Miss Emma Wilson, Marengo, Ill.
Miss S. Shibley, Richmond, Ill.
Mrs. L. Harrison, Peoria, Ill.
Mrs. White, Englewood, Ill.
Mrs. Bischoff, Burlington, Iowa.
Mary A. Davis, Lisle, Ill.
Miss Jennie Hayner, M. D., Chicago.
Mrs. A. C. Starkweather, Wilmington, Ill.
Mrs. F. Wilcox, Mauston, Wis.
Mrs. E. H. Whitney, Chicago.
Mrs. J. Heddon, Dowagiac, Mich.

President Miller started the ball to rolling by reading from the question box, "What kind of bees are best?"

Geo. Thompson, Geneva, Ill., thought that the Syrians, in their purity, undesirable, but considered a judicious cross between them and the Italians an excellent bee. Syrians are very prolific, breed up quickly, and, hence, are very desirable in localities where the main honey harvest comes early in the season.

T. F. Bingham: You speak of a judicious cross, will you please tell us what you mean?

Geo. Thompson: One-third Syrian, the remainder Italian.

Rev. L. L. Langstroth: I have noticed that the Italians stop breeding early in the season. Mr. D. A. Jones told me that he preferred a cross between the Italians and Syrians.

James Heddon: If you were going into bee-keeping again, is it your opinion, Mr. Langstroth, that you would have a pure variety or a cross?

Rev. L. L. Langstroth: It is my opinion that I should prefer a cross.

F. Wilcox: I cannot get the Italians into boxes so readily as I can the blacks.

James Heddon: I have never had a Syrian or Cyprian queen in or near my apiary, and, until we can get better reports from them than we have, I never shall. I see no advantage in very early or late breeding. My bees do not die any more in winters when they cease breeding early in the season. Neither do I consider extra prolificness of the queen anything of

which to boast. Large colonies of young bees, in the fall, winter no better; sometimes not so well.

Wm. Camm: I prefer pure Italians. The Syrians do not properly ripen and seal the honey, and in no manner do they show a superiority over the Italians. Have tried crossing them with the Italians. A Syrian queen mated with a black drone produces a more amiable bee than an Italian queen mated with a Syrian drone, but I never saw a gentle Syrian with any system of management.

E. J. Baxter: With me the Cyprians have no advantages over the Italians, while they are very vicious, even after the hive is closed, they will follow a long distance to sting. I prefer pure Italians. I have tried blacks, but do not like them. I like to have bees breed late in the season, but think extra prolificness of no account.

James Marvin: I prefer the Italians.

James Heddon: If there is a member present who has gentle Syrians or Cyprians, I should be glad to hear from him.

J. A. Green: I have Syrians bred from a queen obtained from A. I. Root, and they are gentle.

James Heddon: There is one difficulty in deciding this question, and that is, all breeders are not honest. And then all bee-keepers cannot distinguish one variety of bees from another. For instance, in 1881, a noted breeder sent me a Syrian queen, and wished me to send him in return a queen of my strain of bees. Now, I did not want the queen in my yard, and I hardly knew what to tell the breeder, but I finally decided, for the benefit of the fraternity, to lay aside my conscientious scruples. What did I do? Well, I will tell you. I took the Syrian queen and put her into one of my shipping cages and returned her, together with a long letter, asking the breeder to give my strain of bees a careful trial, and see if they did not compare favorably in marking, industry, general character, etc., with other bees. He reported a careful examination, and never once suspected they came from him. If I were producing extracted honey, and nothing else, I should be satisfied with the dark, leather-colored Italians, but for the production of comb honey I prefer a cross between this variety and the brown German bee.

J. A. Green: I see no difference in the appearance of Italians and Syrians, but the Syrian queen that I had was one of Mr. Root's selected tested queens.

J. C. Gould: My experience has been that pure Syrians are not so irritable as a cross between Italians and blacks. Queens in Italian colonies are more readily found.

James Heddon: I have no trouble in finding queens in my hybrid colonies.

T. F. Bingham: The purer my Italians are, the least liable are they to swarm. My hybrids swarm most.

James Heddon: The same colony does not behave the same, nor store honey with the same industry each season; why is it?

F. Wilcox: It may be because they are not strong enough at the proper time.

James Heddon: That is not the point; colonies are exactly alike, so near as we can discover, and yet one colony yields an excellent surplus, another none; why is it?

C. C. Miller: It may be caused by a difference in the age of the queen.

James Heddon: I think not; bees supersede their queen when she becomes too old. In regard to varieties, I tried the "golden" Italians, but did not like them so well as the blacks. I tried the dark Italians, and liked them better than either, but I prefer a cross between the dark Italians and the blacks. I do not want the bees to be too black. Most of the black bees throughout the country are the brown German variety.

The following question was handed in for discussion, by Mrs. L. Harrison: "Is it the opinion of this Convention, that legislation is necessary to protect bee-keepers against the ravages of foul brood?"

T. L. Von Dorn remarked that he did not think it necessary, as an indictment could be easily obtained before any grand jury against any one who persisted in keeping such a loathsome disease about his premises.

Dr. S. M. Slade said that it was a disease most-dreaded, and protection should be given against its spreading.

T. G. Newman remarked that special legislation was very often inoperative, and remained a dead letter on the Statute books, but safe guards should be thrown around bee-keepers against this malady. It was a *crime* to keep such a loathsome disease in an apiary, especially if there were any likelihood of selling bees, to endanger its spreading. He believed that it was the safest way to destroy all such colonies, and thus root out the evil.

On motion, the meeting adjourned to meet at 2 p. m.

AFTERNOON SESSION.

Met at 2 p. m. Dr. Miller in the Chair. The first question brought up was that of queen-rearing, which soon branched off, taking a wide range; for instance, James Marvin said that he had clipped the queens wings this season, had never done so before, and would never do so again.

E. J. Oatman: We cannot afford to tolerate poor stock; we must have the best. Old queens do not furnish the best bees. I destroy queens before they become too old.

James Heddon: If the offspring of young queens is the best, we want it, for it requires just as much honey to rear a lazy bee as to rear a smart one.

Dr. Miller: How do bees know when to supersede a queen? Is it because she lays a fewer number of eggs, or how is it? How do the bees know when to supersede?

Wm. Camm: I had a queen that did good service five years, and I presume that she might yet be doing so, if she had not been smothered in a snow bank.

S. M. Slade: I always allow my bees to swarm, and have arrived at

the conclusion that there is more in the operator than in the queen.

Rev. L. L. Langstroth: Bees do not, I think, supersede their queens simply because the queen does not lay enough eggs to suit them. I once put an old queen in several different colonies, and they all tried to supersede her. I then placed her in a nucleus, and that also tried to supersede her. I would like to ask if any one has noticed that black bees are less liable than Italians to supersede their queens. I have found it so. They seem to have more affection for their queen; they are fairly distracted when she is removed. Italians are much more apt to supersede their queens. I have also noticed that the superseding queen is an excellent one.

Wm. Camm: I had two superseding queens, this season, and they were very prolific.

Rev. L. L. Langstroth: We can tell the age of queens by their color. A young queen is bright-colored and fresh looking, more so the first year than ever afterwards. We cannot look at a queen and say, to a certainty, that she is of a certain age, but we can make a pretty close guess.

R. A. Burnett, a commission merchant of Chicago, was next introduced, and, to questions, replied in substance as follows: One-pound sections sell the best. I have handled a few one-half pound sections, but I am of the opinion that if they must be sold at a very much higher price than the one-pound sections, it will not be advisable to use them. I have handled glassed sections, but they are very unsalable. A section that weighs a fraction less than a pound is better than one that over-runs in weight, as we are always asked to "throw in" the extra ounces, while to throw off a few cents because the section is under weight, always creates a feeling of satisfaction. A thin comb of honey is more salable than a thick one weighing the same, as the larger surface of comb makes the amount of honey appear larger. Dark honey is more salable in the extracted form; in fact, it should never be put upon the market in combs. Here the discussion branched off into adulteration of honey.

R. A. Burnett: I have kept it before the public that I sold only pure honey, and my sales have increased. I tell my customers that when they get honey in the original packages, they can be almost certain of getting pure honey, and it is in that shape that I try to sell it.

James Heddon: I think it impossible for producers to profitably adulterate honey.

E. Baxter: I do think it can be done. James Heddon: Will you please tell us, Mr. Baxter, how much you get for your extracted honey?

E. Baxter: Eight or nine cents. James Heddon: How much did it cost you to produce it?

E. Baxter: Perhaps 10 per cent. of its selling price.

James Heddon: Do you think, Mr. Baxter, that you could afford to adulterate, with glucose, honey that cost you only 2 cents a pound?

There was too much of a lanch to clearly hear Mr. Baxter's reply.

S. M. Black: Adulterated honey is easily discovered.

E. Baxter: I am well acquainted with the properties of glucose, and the injuries that it causes; its effects are slow. I think, in time, that it will be so made that it will be wholesome.

T. G. Newman: For a long time it has been impossible to sell honey here in Chicago, because of its adulteration years ago. We have fought glucose as a deadly enemy, and at last we have it under our foot; let us keep it there. I believe it a sin to have it go out to the world that bee-keepers can or will adulterate their honey. The name of a bee-keeper when placed upon a package of honey, should be a synonym for purity—a guaranty for the straight and pure article. No glucose should ever be tolerated in or around his apiary, for it would destroy confidence to be in possession of the vile trash for any purpose.

Rev. L. L. Langstroth referred to Mr. C. F. Muth, and the large business that he had built up by being strictly honest, and dealing in pure honey. One man says that glucose can be made pure; perhaps it can, but it is not done, unless some one writes for a sample to analyze, or something of that kind, when a sample is especially prepared and sent to him.

James Heddon: Heat effects glucose and honey in a different manner. Heat a glass of pure honey, and at the same time one containing honey of suspected purity, and if glucose is present, the ropy, stringy, gluey appearance of that containing the glucose will be easily seen.

J. L. Harris: My experience is that customers can tell the difference between adulterated and pure honey. That is, after using adulterated honey, they soon tire of it and want no more.

Wm. Camm: I agree with Mr. Newman, but we cannot afford to ignore facts. I am happy to be able to say that it is a fact that every bee-keeper is opposed to adulteration.

M. L. Trester: Many purchasers of honey store it in a damp place, where it will absorb water and will sour, and then they say that it is adulterated. The label should explain this matter. Honey appears to much better advantage when stored in flint instead of ordinary glass vessels. Producers should establish a reputation in their home market. No stranger can come into my market and sell honey.

At this point the convention was favored with some music and the singing of some "bee songs," such as "Charley the Bees are Swarming," etc., by Mr. and Mrs. F. Edgecombe, of Chicago, Prof. Coffin presiding at the organ.

A vote of thanks to Prof. Coffin and Mr. and Mrs. Edgecombe was unanimously passed for the musical entertainment.

Then followed the election of officers which resulted as follows: President, Dr. C. C. Miller, Marengo, Ill.; Vice-President, Mrs. L. Harrison, Peoria,

Ill.; Secretary, W. Z. Hutchinson, Rogersville, Mich.; Treasurer, T. G. Newman, Chicago, Ill.

Upon motion of T. G. Newman, it was decided that, at future elections, to save time, the Secretary should furnish printed ballots, with blanks left for names of persons to be elected, and so arranged that all the officers could be elected at one ballot.

The meeting then adjourned to meet at 7 p. m.

EVENING SESSION.

The first subject discussed was that of "Over-stocking a Locality."

The greater part of the time set apart for this discussion was taken up in listening to reports from members regarding the number of colonies that they pastured upon certain tracts of land. Dr. Miller finally asked how many members present had kept more bees in one locality than could be kept with profit. Ten members stood up. The discussion that followed brought out the idea that, as a general thing, an apiary should not contain more than 125 or 150 colonies, and the field should be clear three miles in each direction.

Dr. Miller: When our locality becomes over-stocked, what shall we do? Shall we sell some of our bees? Shall we plant for honey, or what shall we do?

F. Wilcox: Plant Alsike clover.

A Member: Upon what soil do plants furnish the most honey?

L. H. Scudder: One plant in my locality does best upon light sandy soil.

A Member: What plant will it pay to cultivate for honey alone?

Geo. Thompson: Sweet clover.

J. A. Green: In my locality, sweet clover grows upon the river banks, where there is little else except pure sand.

Wm. Camm: I prefer figwort. Sweet clover will not grow upon every soil. I tried some upon clay, and it did not grow. I have sowed sweet clover in the spring; it made a fine start, but the drouth killed it. Sowed some in the fall with better success. By enriching the ground, I have made sweet clover blossom. I consider it an advantage to cut it in June.

James Heddon: There is one kind of soil in which sweet clover will grow every time, and that is gravel.

James Marvin: My neighbor, M. M. Baldrige, had, in one season, 75 acres of Alsike clover, and from it my bees gathered a large crop of very superior honey.

James Heddon: Is there any one present whose income has been increased by planting for honey alone?

Dr. Miller: My bees fairly revel upon my figwort, but I cannot be certain that it has paid me; because bees work upon blossoms, is no proof that it pays to raise them.

Wm. Camm: After harvesting a crop of oats, I have plowed the field and sowed it to buckwheat, from which I have obtained a crop of honey more than sufficient to pay the expense.

S. N. Black: And I have sowed buckwheat in a corn field, after it was

cultivated the last time, and received from it enough honey to make it pay.

T. L. Von Dorn: I have a neighbor who has had large crops of honey from rape.

James Heddon: I have a student from Nebraska, and he says that his father regards matrimony vine as a great honey producer.

T. L. Von Dorn: I agree with this gentleman.

The meeting adjourned to meet at 9 a. m.

MORNING SESSION.

The Convention met at 9 a. m. according to adjournment. President Miller announced for discussion "Surplus receptacles."

As the subject seemed a little slow in starting, President Miller said: Who raises extracted honey? Up with your hands. Now, who raises comb comb? Two-thirds of the members made a specialty of comb honey.

Dr. Miller: Now, who uses separators? To the surprise of some, it was found, upon voting, that three-fourths of the members could get along without separators.

Mrs. L. Harrison: If we sell at home, there is no necessity of using separators, but if we have to crate and ship our honey, it is a different thing. I have my honey stored in boxes.

W. Z. Hutchinson: In regard to crating and shipping honey built without separators, please allow me to say that I, this season, raised 2,600 pounds of comb honey without separators, crated every pound, shipped it by freight to the State Fair at Detroit, shipped it back by freight, and carried it 12 miles in a lumber wagon to our County Fair without the loss or breakage of a single comb.

As Dr. Oren came in at this point, the President thought it best to resume the subject of pasturage, in order that Dr. Oren might tell more about a honey plant of the helianthus order, which he had on exhibition. It blossomed in September, and continued in bloom until cold weather, while the amount of honey gathered from it was very great.

Geo. Grimm: I have had considerable experience with the same plant. It grows along the river bank, and we often haul our bees 30 or 40 miles in order that they may work upon this plant.

Wm. Camm: I have had experience with this plant, and find it valuable. I have tried Dr. Tinker's golden honey plant, and with me it is worthless.

The question of surplus receptacles was again taken up.

James Heddon: No one considers sections cratable unless the combs do not touch, but the thicker the combs, provided that they do not touch, the better, for the reason that thick combs are not so easily broken out. Honey raised without separators is thicker, and better fastened to the wood around the sides. I want no sections with closed tops, but those with open top-bars clear across. With closed top-bars the bees have no guide, and do not know where to have the edge

of the comb. With open top-bars they do have a guide. Where the openings in the top and bottom bars do not extend clear across, those little projecting corners are liable, in crating honey or taking it from the crate, to gouge into the sides of the neighboring combs. To get straight combs the sections should be filled with Given foundation, the hives should stand level, except slightly raised at the back. Bees having a dash of German blood are a great help in getting straight combs. To get sections holding half-pounds, I reduce them in width and thickness. Half-pound sections ship better, because they are smaller. One of my customers found the half-pound sections very salable; other sizes were a drug as long as they lasted; the same was not always true. I have tried wide frames, and the case method upon a large scale, and I expect to burn up the wide frames, and use the cases exclusively.

F. Wilcox: In some colonies I can get straight combs, in others not. Strong colonies build straight combs, weak ones are not so apt to.

Dr. Miller: Too thin foundation sometimes causes crooked combs. Foundation made upon a press is less liable to warp or bend than that made upon a roller mill. I do not like the Van Dusen foundation; it is too thin, and curls too much. I wish to make a point, that the kind of foundation made has much to do with the success of crating sections.

Rev. L. L. Langstroth: I believe that this Convention represents the largest number of large, practical, successful honey producers of any Convention that I have ever visited. Mr. Langstroth here gave a long and interesting account of how the invention of the movable comb hive was brought about, and then spoke with much feeling of

THE HONORED DEAD.

Mr. Samuel Wagner was first mentioned. He told how Mr. Wagner had taken him by the hand and helped him. How fair, square and liberal he was. His library was full of bee-keeping works, and free access was given to all who wished to read them.

Moses Quinby and Mr. Langstroth published their works at about the same time, and it was a great source of pleasure to know that they so nearly agreed. Mr. Quinby had learned how to make money at bee-keeping, even when using box hives. Mr. Quinby had told Mr. Langstroth that the happiest moment of his (Quinby's) life was when he read to his family, from Mr. Langstroth's work, commendatory words in regard to himself.

Adam Grimm had done very much for bee-keeping, had shown that a fortune might be amassed in the business. Mr. Grimm had once visited Mr. Langstroth, and his greeting was: "Hail, great American bee-keeper!"

Richard Colvin had spent thousands of dollars in helping forward bee-culture.

R. C. Otis had, perhaps, been the most instrumental of any one in dis-

BEES AND HONEY FOR 1883.

seminating movable combs throughout the country. Had it not been for him, movable comb hives might now be but little known. He was a kind-hearted man, and would leave everything else and care for his old mother.

At the close of Mr. Langstroth's address, Mr. Geo. Grimm, Adam Grimm's son, arose and thanked him for the eloquent words spoken of his father, and moved that a vote of thanks be given Mr. Langstroth for his loving words in regard to those who were dead and gone, which was unanimously carried, while heartfelt tears welled up in many eyes.

While a statistical table (which appears elsewhere) was being prepared, Mr. Langstroth exhibited to the members a bottle of alcohol containing a drone and two workers of *Apis-Dorsata*, which had been given him by Mr. D. A. Jones. While the workers were larger than our queens, the drone was not larger than our drones, and Mr. Langstroth expressed a hope that it might be possible that a cross might be obtained by the mating of an *Apis-Dorsata* drone with one of our queens.

After the statistical table had been prepared, the Convention adjourned to meet at 1:30 p. m.

AFTERNOON SESSION.

Meeting called to order at 1:30 p. m. President Miller in the chair. The subject first taken up was "Foul brood."

Dr. Miller said, that the disease could be discovered by the odor, and by the appearance of the dead brood. There were three remedies. First, cremation; secondly, the starvation plan, and thirdly, the use of salicylic acid.

Mr. Marvin and others advocated total destruction as the only sure remedy, and all agreed that great care was necessary that the disease might not spread.

The subject of "Wintering" was then taken up.

J. E. Hunter: I put my bees in the cellar when steady cold weather comes, and winter without loss. I take them out when it becomes so warm that I cannot keep the bees quiet. I have both upper and lower ventilation, and aim to keep the temperature at 45°.

Dr. Miller: Thermometers vary; bee-keepers should look out for this.

E. J. Baxter: I wintered 110 colonies, last winter, out-of-doors without loss. My hives are not shallow. I always try to have good, strong colonies, and plenty of good honey for stores. I leave in only eight combs, filling up the empty space with dry leaves, spreading a mat over the top of the frames.

E. J. Oatman: I shall winter 600 colonies out-of-doors, and 11 in the cellar. I put those 11 in the cellar because they are in shallow hives. I prefer out-door wintering with the hives protected by chaff; and I do not unpack them until all danger from cold is over. I prefer confectioners' A sugar to all other stores for wintering. We are not always certain that the honey is pure; it may be

gathered from cider mills or something of that sort. The syrup should be made in the proportion of five quarts of water to twenty pounds of sugar, and it is better that it be fed in time to be sealed over before cold weather. I began feeding Sept. 11. I would commence feeding as soon as the honey flow is over. I would not feed in winter unless as a last resort to prevent starvation.

Wm. Camm: I never lost a colony that went into winter quarters in proper condition. I never extract honey from the brood-chamber. I do not want any sugar; think honey good enough. I do not care for pollen; give the bees room enough to store plenty of honey, and they are all right.

Dr. Oren: What would be the result of confining bees to a diet of pollen?

E. J. Baxter: Mr. Dadant has never tried to avoid pollen, and has always had good success.

S. M. Shale: During three or four years I wintered my bees without loss in a cellar, but one year 3 or 4 colonies became restless and ate up all their stores and died of starvation. At last they came a winter in which my bees and those of my neighbors died. It followed a season in which we had no surplus honey.

Dr. Oren: I had a weak colony of blacks that had no queen in August. When I put them in winter quarters there was not more than a pint of bees, but I gave them an Italian queen. In the spring all the black bees were gone, and in their places were Italians; plenty of them. They wintered well.

E. J. Oatman: I think that pollen is at the bottom of much of our winter troubles. One reason for feeding sugar is to cover the pollen, so that the bees cannot get at it.

James Heddon: All our losses are nothing compared to that caused by dysentery. Now, what causes dysentery? Does any body know? Has laying a little stick over the frames got anything to do with it? Has turning back the quilt one-eighth of an inch at the back of the hive anything to do with it? Has a little chaff here, and a little chaff there anything to do with it? Has ventilation anything to do with it? Do not bees die out-of-doors and in the cellar, when they are ventilated and when they are not ventilated, when they are kept dry and when they are kept in a damp cellar, and do not they live sometimes under just these same circumstances? Confinement is not the primary cause of dysentery, neither is cold, nor confinement. Now, what is it? It is my opinion that the trouble is in the food. Pollen is what causes the trouble. Grains of pollen are often floating in the honey. Pollen is a needed food in building up tissue, as in rearing brood or repairing the waste tissue when bees are laboring in the field, but it is not needed when bees are quietly clustered in the hive during the winter. A heat producing food is then needed, and for this purpose pure cane sugar is better than honey. It is also more completely digested, leaving a smaller amount of

residue. This pollen theory is the only one that will fit all cases. A man puts his bees in the cellar, or in a clamp, and leaves them there five or six months, and they come out in fine condition; the confinement did not bring on the dysentery did it? The next winter, with even a less amount of confinement, they may all die. Dampness does not cause dysentery; if it does, why did it not kill that man's bees who kept them in so damp a cellar that the hives were dripping with moisture, and a large number of combs blue with mold? If cold causes dysentery, why is it that bees often winter best in a long, steady, cold winter where the mercury often goes down below zero, and stays down a long time. Cold, dampness, and confinement may be aggravating, but they are not primary causes. Pure cane sugar is the remedy for their troubles.

E. J. Baxter: I have quieted restless colonies by giving them more ventilation.

Rev. L. L. Langstroth: I cannot think that the Creator would make things so antagonistic to each other. The instinct of the bee teaches it to gather, store and eat pollen; hence, it should be healthful. Cold does not always cause dysentery. I have known bees winter successfully, in a severe winter, when the hives were raised from the bottom-board, and in some instances where the bottom-board had fallen off entirely. I have had persons experiment by hanging up a colony, combs and all, of course, but without any hive, in large boxes, or in a smoke house, and, although the winter was severe, they wintered perfectly.

James Heddon: I would say to Father Langstroth, that I do not claim that the bee will eat pollen, during the winter, from instinct, but they are sometimes compelled to eat it.

The next topic of discussion was "Comb foundation."

E. J. Oatman: I prefer the Given to all others. Think 7 square feet to the pound about right.

James Heddon: I prefer the Given foundation; for sections I would have it about 8 feet to the pound. For putting foundation in brood frames, the Given has no competitor.

E. J. Baxter: That Mr. Dadant has, the past season, made 45,000 pounds of Dunham foundation, is something in its favor.

Geo. Grimm: I have laid aside the Dunham mill for the Given press. I prefer the Given foundation both for surplus and for brood combs. The base of the cells are always thin, even in a heavy sheet of foundation, and as it is the base only that receives the pressure, the side walls are soft.

Dr. Miller: I like the Given foundation best, but I have noticed that it is not always of uniform thickness, some parts of the same sheet being thicker than others.

James Heddon: The base is so very thin in the Given, that any difference is more perceptible.

T. F. Bingham: As the bees are obliged to add some wax in order to finish the comb, what material differ-

ence does it make if some parts are a trifle thicker than others? I think that the excessive pressure of some mills makes the foundation too hard; and the bees are thus liable to thin the base if it needs it.

The next subject was "Fastening Foundation in Sections."

E. J. Baxter: I fasten it in by pressing it in with a knife.

Dr. Miller: I prefer the Clark fastener.

F. Wilcox: I never tried the Parker fastener—use the Clark. In removing the section, I pull out one corner first, which answers the same purpose as the sliding-back movement of the Parker. I fasten foundation in the brood frames with a putty knife.

Dr. Miller: I do not twist the section in removing it from the Clark fastener, and the starters do not fall out.

James Heddon: No other fastener except the Parker has that sliding-back movement, and, without that, I consider no fastener as perfect.

Geo. Grimm: I fasten mine with melted wax and a brush; I keep the wax at the proper temperature by means of a lamp.

Upon the subject of "Purifying Wax," Mr. Black said: Melt it with large quantities of water; let it cool slowly while upon the water, and all impurities will settle to the bottom.

The question was asked: Is it profitable to prevent after-swarming?

F. Wilcox: Yes.

Mr. Black: It depends upon circumstances. Second swarms are often the best; especially is this so if they come during a good flow of honey, when they can build up quickly. The succeeding year they are the very best of colonies.

James Heddon: Some, to prevent after swarming, cut out the queen-cells. I object to this. There is something in nature that hatches the best queen first. Now, I will tell you how I manage second swarms. I have them upon frames of wired foundation, and place the hive containing them by the side of the old colony. As soon as the queen is fertilized and laying, I shake the whole swarm down in front of the old hive, and put away the drawn-out foundation for future use. All the bees being the offspring of one queen, they do not quarrel. I have tried uniting bees; some seasons they did not quarrel, others they did.

Geo. Grimm: I hive an after swarm, and place it by the side of the old colony, and then at evening shake it down in front of the old hive.

James Heddon: Yes, I have tried that plan, but the next day out came the swarm again.

"Prevention of robbing and uniting bees."

Rev. L. L. Langstroth: If it is in order, I should like to tell how Mr. D. A. Jones manages robber bees. He has found that one dry bee can conquer a large number of wet ones; hence, when there is any fear that robbers may over-power a colony, he piles hay in front of the entrance, then wets some hay and puts over this, and the result is, that the robbers become wet and are easily over-

powered. Mr. Langstroth had also successfully united colonies that were inclined to quarrel after he tried to unite them, and it was done by wetting with sweetened water, the colony that was at home. The intruding colony had no desire to fight.

The Convention adjourned to meet again in Chicago upon the Wednesday and Thursday of the last week of the Exposition, when held in 1884.

W. Z. HUTCHINSON, Sec.

For the American Bee Journal.

Worker Bees in Queen-Cells, etc.

G. M. DOOLITTLE.

On page 433, I see that Mr. Heddon is puzzled by that "Curious freak of bees," given by Mr. Rickenbacher.

Mr. R. says that, while cutting out queen-cells, one of them fell to the bottom-board unnoticed, and in it he afterward found an old dead worker bee. As he says he did not notice it at the time it fell to the bottom-board, I take it for granted that it did not fall there, but that the bees built it there, for I have frequently found queen-cells built by the bees in all sorts of places in the hive, some of which was more strange than a queen-cell on the bottom-board to the hive.

Mr. R. further states that, at the time he cut out the queen-cells he grafted in a cell from an Italian colony, the queen from which went out with a swarm a few days afterwards. He then asks why the bees sealed the cell with the dead worker in it, and then swarmed. Here again I take it for granted that the queen-cell with the dead worker in it had nothing to do with the swarming of the bees, for a swarm of bees know whether a queen-cell contains an embryo queen which is alive or not, just as well before it is opened as Mr. R. knew what was in the cell after he had opened it. I have seen this verified in many instances, when queen-cells have been chilled so as to kill the young queen.

The way the worker came in the cell was this: As soon as the young queen emerged from the cell, the worker went in to partake of a royal jelly diet, as bees always will do. While the bees were in the cell, the cap to the same was pushed shut by some of the bees, when it was fastened there, thus securing the unfortunate worker a prisoner, after which she died; hence was found dead. Many of such cases have come under my notice.

Now, why did the bees swarm with the Italian queen? Probably from one or two reasons, the most likely of which is that this queen from the cell on the bottom-board hatched about the same time that the Italian queen did (from the cell inserted). Of course one must be killed, and the bees saw fit to keep the Italian and kill the other. The Italian queen became old

enough to take her wedding flight, and the bees (a swarm) went out with her, which is no uncommon occurrence, by any means. The other reason would be, that this queen from the cell on the bottom-board hatched and was killed as before, while, in some out-of-the-way place, was a queen-cell not so nearly mature, which escaped the notice of Mr. R. As this cell came to maturity later, the bees swarmed after the few days, under the same conditions as a second or third swarm issues, and both queens went with the swarm, as is often noticeable, especially with third swarms, as the parent colony is often left queenless by all the young queens going out with a third swarm. In any event there can be no question but what a queen had hatched from the cell in which the dead worker was found.

IS SMOKE INJURIOUS TO BEES?

On page 483, I am asked "Whether the very pungent smoke from the use of sound wood in bee smokers has no deleterious effect on the delicate larvae and eggs of the bees." I have smoked a patch of eggs and larvae thoroughly, and marked the same by sticking wire nails around it, but have never found any of the brood removed by the bees, but all were sealed over and came out perfect bees; hence I conclude that smoke from any kind of wood is not deleterious to the bees or the brood.

CHILLED BROOD.

Not so with unsealed brood when it is exposed to a temperature which is below 55 to 60° F., for I have often marked patches of brood as above, from which the bees had withdrawn when the frames were handled in a low temperature, and I have invariably found that the bees removed all such brood as was exposed, even for a few moments at a time, outside of the hive. In the spring of the year, when the weather is generally cool, and the bees are few, considerable loss is likely to occur in this way, unless the operator is very careful. Especially is a cold wind liable to injure the brood, for the cold air is forced into the cells at such a time, while if the day was still, the few bees which were on the comb might protect it for a short space of time. In a still day, no harm will result, as long as the bees keep spread out evenly over the brood; but as soon as they begin to draw together, thus leaving apart of the brood exposed, you may know that you will lose much if you proceed with your operations. At such times it is best not to open the hives, but if such is necessary to be done, and the hive is full of frames of comb, I select such as has no brood in it, setting it outside of the hive. This will give room to manipulate the others easily, and by being as expeditious as possible, I rarely get any brood chilled, since I have found out how to guard against it. In early spring, brood is of much value, and he who can so work his bees here at the North, so as to get the greatest amount of brood during the month of May, will be the most certain of success.

Borodino, N. Y.

Rural New Yorker.

A New Bee Enemy.

PROF. A. J. COOK.

It has long been known to chicken fanciers that our poultry often suffer serious injury from a small mite. I have seen these little pests, red with the internal juices, so thickly clustered on boards, etc., in the poultry house, that to grasp the board meant death by crushing to thousands of these infinitesimal pests.

It has long been known that other mites attacked others of our domestic animals, like the cow, the horse, the sheep, etc. Other mites attack sugar, flour and cheese. The little red spider—also a mite—so thrives in a dry atmosphere that house plants are often destroyed by its blighting attacks. I have known the tidy housewife to be seriously annoyed by mites which had come from birds that had nested just above her window. The little vital specks fairly swarmed on the window panes. Other mites take up their abodes between the bases of the human fingers, while others still smaller inhabit the face pimples even of the graceful belle.

That insects are often preyed upon and destroyed by mites is a well known fact. Newport described a mite which he found on the larvae of a wild bee; but that our honey bee is

A New Bee Enemy—from life.

attacked and even destroyed by these little living particles is recent and most unwelcome news.

During the past spring a lady bee-keeper of Connecticut discovered these mites in her hives while investigating to learn the cause of their rapid depletion. She had noticed that the colonies were greatly reduced in number of bees, and upon close observation she found that the diseased or failing colonies were covered with these mites. The strong and prosperous colonies were exempt from the annoyance. So small are these little pests that a score could take possession of a single bee, and not be near neighbors either. Mrs. S. feels certain that she found the same kind of mites on the church window where she resides. Upon request she sent me some of these latter which were lost in the mails. The lady states that the bees roll and scratch in their vain attempts to rid themselves of these annoying stick-tights, and finally, worried out, either fall to the bottom of the hive or go forth to die outside.

Mites are not true insects, but are the most degraded of spiders. The sub-class Arachnida are at once recognized by their eight legs. The order of mites (*Licarina*) which includes the wood tick, cattle tick, etc., and mites, are quickly told from the higher orders—true spiders and scorpions—by their rounded bodies, which appear like mere sacks, with little appearance of segmentation and their small, obscure heads. The mites alone of all the Arachnida, pass through a marked metamorphosis. Thus the young mite has only six legs, while the mature form has eight.

The bee-mite is very small, hardly more than five m. m. (1-50 of an inch) long. The female is slightly larger than the male, and somewhat transparent. The color is black, though the legs and more transparent areas of the females appear yellowish. As will be seen by the figure, which shows the form and structure very accurately, the anterior legs are the longest. All the legs are five-jointed, slightly hairy, and each tipped with two hooks or claws. Each of the mouth organs is tipped with a tuft of fine hairs.

The eggs which show through the body, as seen in the drawing, are mere specks of a red color, and from the fact that there are several sizes in the gravid females, indicating separate crops, it is probable that these females are not creatures of a day, but possess quite a longevity. The mites were sent me in a bottle, and when they arrived there were very numerous eggs and several of the young six-legged mites occupying the vial with the more mature forms.

REMEDIES.

The fact that what would be poison to the mite would probably be death to the bees, makes this question of remedy quite a difficult one. I can only suggest what Mrs. Squire has tried—frequent changing of the bees from one hive to another, after which the hive can be freed from the mites by scalding. The trouble with this cure is the rapid increase of these Liliputian pests, and the fact that many would adhere to the bees, and so be carried along with them, and so escape the hot-water bath. Of course, the more frequent the transfer, the more thorough the remedy.

IMPORTANT SUGGESTION.

I would suggest placing pieces of fresh meat, greased paper, etc., in the hives in hopes to attract the pests, which when massed on these decoys could easily be killed. If thought best, the traps could be screened by placing them in a box made of fine wire gauze so that the bees could not reach them. In such screens I should try placing paste-board smeared with a thin coat of thick syrup, to see if the mites had a sugar tooth to lure them to destruction. On such a sticky surface it would be well to sprinkle flour, sugar, etc. If we can find in this manner some substance that will attract these little destroyers, and call them off of the bees, the battle is won.

Lansing, Mich.

SELECTIONS FROM OUR LETTER BOX

The Michigan Convention.

DEAR MR. EDITOR:—May I ask you to call special attention to our next annual meeting to be held in Flint, Dec. 6 and 7, of the Michigan Bee-Keepers' Association. We expect to have by far the best meeting ever held in the State. It is expected that the Rev. L. L. Langstroth will be present. To see and hear him will pay any one for the trouble and expense incident to the journey. We also expect D. A. Jones, A. I. Root, C. F. Muth, and hope to have C. C. Miller and T. G. Newman. From what I hear, Michigan bee-keepers are to be out in force. Hotel rates are to be \$1.00 a day. Further particulars as to programme, will be given soon. We expect to get reduced rates on the railroads. To aid in this, and that I may know how many certificates on railroads to ask for, will every one in this or other States who expect to come, drop me a card at once to that effect?

A. J. Cook, President.

Lansing, Mich., Oct. 15, 1883.

Foul Brood.

PROF. COOK, SIR: Hearing of the case of foul brood in Mr. Rider's apiary, at Howell, Mich., I gave an account of it at the Northern Michigan Bee-Keepers' Convention, recently held at Sheridan. Another man present gave an account of a case thought to be foul brood near Grunville, where the man had destroyed them. He also thought that there was a disease of the brood at a Mr. Lincoln's, near the same place. I being appointed one of a committee, I will try and tell you what I found. I went to Mr. Lincoln's accompanied by Uiram Rossman, a friend of H. Moon. We found a colony of bees in an old style of hive, badly diseased. Brood-rearing was in progress to quite an extent, but nearly all of the capped brood was dead, and in most all of them was a dark, ropy substance, and very offensive in smell. I will mail you a sample of the same. Mr. Rossman told me that in 1876, 17 years ago in the spring, that he and Mr. Moon, while transferring a colony from a box hive for a Mr. Taylor, that they came across what Mr. Moon said was a case of foul brood; there was a large amount of brood, and it was a mass of corruption, and the smell was bad. Mr. Rossman says the two cases are identical. Please send this with your answer to the BEE JOURNAL, and oblige many bee-keeping friends.

S. J. YOUNGMAN.

Cato, Mich., Oct. 13, 1883.

[The sample sent is plainly "foul brood." The characteristic odor, the concave cappings, the central puncture to the cap, and the decaying brood, which, when drawn out, is brown and stringy, all indicate but too plainly that the full destroyer is at hand.

The colony at Mr. Lincoln's should be burned at once, hive and all. Other colonies in the neighborhood should be examined, and if the disease shows itself, it will be most wise to burn all such colonies. It may be best in a large apiary to try to cure by the salicylic acid method, as explained in my book, or by the starvation plan; but with but a few afflicted colonies, a man owes it to himself, and surely to his neighbors, to burn at once. I have given such advice to several sufferers this summer, and all who have tried it seem to have succeeded well. This stamping-out process should be prompt, for let the "foul brood" once get into the trees in the woods (and what is to hinder), and it will be like Banquo's ghost, "it will not down."

Foul brood seems to have a wide range. Within a week I have received a sample of it from Louisiana, where it is creating sad havoc.—A. J. COOK.]

The Cure of Foul Brood.

How about foul brood, and who is bothered with it among their bees? If any there be that have thus been troubled, we suggest that a doctor be sent for at once. But not that doctor who had it in his own apiary for ten years, tusseling and testing in *his way* many remedies, and finally made a failure. (This happened in Cincinnati, Ohio.) How does this sound coming as it did from a bee-keeper who thus reported last fall at a North American Bee-Keepers' meeting?

[EDITOR BEE JOURNAL:—Above please find a slip from the *Grange Bulletin*, of Sept. 20, which please reproduce. It sounds so much like a slur that it requires a reply. You know I have never charged a cent for giving my experience to others.

We all know that the greatest ignorami are the most apt to exaggerate and to belittle others. There are such folks among bee-keepers, but I do not wish to put Mr. Hicks in that class; will rather take it for granted that he meant a good-natured joke, yet his joke needs a reply, and I will give it as follows:

I will put fifty dollars against his ten that he will not cure a colony of bees infected with the malignant foul brood unless he uses my remedy, giving him his own time for the work. He can select a place within 20 miles of Cincinnati with some reliable man; I furnish the infected colony. I don't think that I have a case of malignant foul brood in my apiary, but I know where to get it. Furthermore, I will put five dollars against one, that Mr. Hicks cannot prove ever to have seen

a colony of bees infected with the malignant foul brood.—C. F. MUTH.]

[In the above quotation from the *Grange Bulletin*, the question is asked, "How about foul brood? and who is bothered with it?" The BEE JOURNAL would like to know who is bothered with it. Let those who are troubled with it speak out. We hear that there are several, and the fact that so many are inquiring, shows that there is danger about this dreadful disease spreading. Prof. Cook is right in saying that "the stamping-out process should be prompt." Its existence will be known, and no one can afford to cover up the facts, if they have it in any form. To sell diseased bees is nothing less than a *crime*, and is recognized as such by the laws of several States, notably in Michigan, we believe. Prompt remedies must be used, and we fear the *only sure remedy* is the entire destruction of the diseased colonies.—ED.]

A Specialist's Report.

I hope any brother bee-keeper will not think that because no communication from me has appeared in the BEE JOURNAL for nearly a year that I am one of the disheartened, who, after their enthusiasm has cooled, loose all interest, for I am not encouraged by the past season, but, quitting everything else, have thrown myself wholly on bee-keeping for a living. The season was not so good as it was a year ago, as the season did not last so long, but I closed it with 3,000 lbs., half extracted, and 100 colonies of bees. I need not report in detail, but close by wishing for all interested, as much good fortune as I have been favored with.

WM. CARM.

Murrayville, Ill., Oct. 16, 1883.

Tiering up—A Correction.

In the report of the North American Bee-Keepers' Convention, published in the BEE JOURNAL, I am made to say that I champion the practice of putting empty sections *above* the full ones in tiering up, or at least to second Mr. Hall in it. What I did say, was that I put empty ones *under* the full ones. This I have practiced throughout the entire season. It is, I think, the common practice, and very advantageous. Toward the last part of the honey flow, however, if empty sections are still put under, the bees commence on them immediately, and the bee-keeper has the annoyance of a lot of partly-filled sections on hand. In many cases they are not needed at all, as the bees only gather enough honey to finish up the sections already on. I have been so much annoyed by this, that I had made up my mind that hereafter I would put empty sections under, until I thought likely that the flow would soon cease, then I put a tier of empty sections on top, where the bees would be rather slow

to commence work, unless actually crowded for room. Mr. J. B. Hall, being just so much more wide awake than I, has been practicing on this plan, and so stated in the Convention, and I said that I intended to practice it in the future, especially after his recommendation. But I think no one present could easily have understood that either of us recommended the general practice of putting empty sections above full ones. By the way, I wish we could oftener see communications from Mr. Hall. I know it would be profitable. I shall not soon forget a very pleasant interview I had with him at Toronto, as he explained to me, in his jovial and gentlemanly manner, his various fixtures and plans. He very strongly impressed me as a master high up in our calling.

C. C. MILLER.

Marengo, Ill.

[Mr. Hall has also sent us a correction of this report by our reporter. But as the above covers the whole ground, perhaps it is not necessary to publish both now.—ED.]

Lousewort *Gerardia* for Honey.

I send a small portion of the top of a plant I found while bee-hunting. It is new to me, as I never saw anything of the kind in this vicinity. I found it in a small clearing, on a high stoney ridge, that, until the past winter, had been covered with a heavy growth of oak timber. It was growing single and in small clumps from 6 to 18 inches high; and notwithstanding the severe drouth that has been raging for the past six weeks (and is still raging), its foliage and bloom was remarkably fresh and vigorous. I found no honey-bees on its blossoms, but mason, tailor and humble-bees very plentifully. Its blossoms emit a very agreeable fragrance, and if they yield nectar acceptable to the honey-bee, its abundant bloom, its season of bloom, and apparent perfect immunity from the effects of drouths, must constitute it a valuable late honey plant. Please give its name in the BEE JOURNAL.

JAS. F. LATHAM.

Cumberland, Me., Sept. 17, 1883.

[Prof. T. J. Barrill says: "This is *Gerardia pedicularia*, or the Lousewort *Gerardia*. There are, in eastern North America, 10 species of *Gerardia*, all having quite showy flowers. Many attempts have been made to cultivate them, with failure in every instance, though the seeds readily germinated and the young plants apparently made a good start. Finally the secret was discovered in the fact that they are root parasites, securing more or less of their food substance from the roots of trees. The nectar is no doubt good enough, but from what has just now been said, this plant can hardly be depended upon as a honey producer."—ED.]

Catching Issuing Swarms.

I am amused at Frank R. Roe's method of catching and hiving issuing swarms, as noted on page 257 of the BEE JOURNAL. Just think of his running four miles in three-fourths of an hour, sweating like a running horse in fly time, over fences, through flax, oats, barley, corn, woods, logs and brush, and fording a river to get nothing but a well-heated system, say nothing about the value of his time, the torn clothes, and worn-out boot leather. Now, in this part of the county, we take a different course. If we desire to work to in the field we trust the children (whose time is of no great value) to attend the swarming; on the other hand, if we attend the swarming ourselves, we will have some other employment about our apiary, such as arranging our honey racks, sections, hives, or extracting etc., etc., and when our ear tells us that a swarm is issuing, we go and adjust a catcher, and then return to our work, leaving the issuing swarm to take care of itself. They soon cluster, and never heat as Mr. Roe's did, in his nail keg. We have perfect control, our bees do not get angry, and we put them in a hive when we get ready.

J. W. BAILEY.

Ripon, Wis., Oct. 15, 1883.

Sweet Clover.

Is sweet clover classed with noxious weeds in Illinois? Can it be sown in highways, with impunity to the sower?

ALFRED MORTAY.

Ottawa, Ill., Oct. 15, 1883.

[It is not classed with noxious weeds, and can be sown anywhere with impunity that one may sow any other ordinary weed.—ED.]

Bees Ready for the Cellar.

My 51 colonies of bees are now ready for the cellar at short notice, but I had to do considerable feeding to get them in good condition for winter. I commenced in the spring with 30 colonies, most of them in good condition; I took 1,350 pounds of comb honey and 100 pounds of extracted. There were 300 pounds of unfinished honey, which I fed back to the bees, and 125 pounds of granulated sugar, which left me 1,050 pounds of nice salable comb honey, and 100 pounds of extracted, which I sold in our home market at 15 cents per pound, and had plenty of orders for more. Last year I only had half as many bees, spring count, and got 900 pounds more honey and more increase. My best colony gave 85 pounds of surplus, this year, and no increase. Last year my best colony gave 235 pounds and one swarm. So we hardly had half a crop of honey here in northern Illinois. I use full sheets of comb foundation for increase, and good starters for surplus honey.

H. T. HARTMAN.

Freeport, Ill., Oct. 15, 1883.

Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper, shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter, on your label, notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a statement of account every week.

Trial Trip, until Dec. 31.—25 cents.

Wishing to be able to reach several thousands of the old-fashioned bee-men, and by the aid of the BEE JOURNAL to lift them up to higher ground, adopting newer methods and progressive ideas, we make the following very liberal offer: We will send the Weekly BEE JOURNAL till Dec. 31, *on trial*, for 25 cents. In order to pay for getting up Clubs, we will give a copy of Fisher's Grain Tables, or Scribner's Lumber and Log Book, to any one who will send us five trial subscriptions (with \$1.25); for a club of ten we will give a cloth copy of Bees and Honey; for a club of 15, a cloth copy of the 7th edition of Cook's Manual of the Apiary; for a club of 25, we will present both the Manual and Bees and Honey. If any one wants these Books for nothing, here is an excellent opportunity to get them for a little exertion.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for ten cents.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey at Fairs, will sell almost a fabulous quantity of it.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Books at Fairs.—Those who make an exhibit at Fairs will find that an assortment of Books and Pamphlets would sell and leave them a profit for handling. We will send such, postage prepaid, at 25 per cent. discount; or if the purchaser pays express charges, we will supply any of our own publications at 40 per cent. discount.

The new two cent rate of postage for letters went into effect on October 1. Three cent postage stamps will now be but little used. For all fractions of a dollar sent to us hereafter we should prefer either *one-cent*, or else five or ten-cent postage stamps, or a Postal Note. Do not send coins in any letter.

Fairs.—To any one exhibiting at Fairs, we will send samples of the BEE JOURNAL and a colored Poster, to aid in getting up a club. The Premiums we offer will pay them for so doing. For a club of 8 subscribers to the Monthly BEE JOURNAL, or 4 Weekly, we will present Dzierzon's Rational Bee-Keeping, price \$2.00.

Convention Notices.

The Northern Michigan Bee-Keepers' Association will be held at Alma, Mich., the second Tuesday and Wednesday of October, 1884.

F. A. PALMER, Sec.
McBride, Mich.

The fall meeting of the Northern Ohio Bee-Keepers' Association will be held in the City Council room at Norwalk, Ohio, on Thursday, Oct. 25, 1883, commencing at 10 a. m. A full attendance is requested.

S. F. NEWMAN, Sec.

Please announce that the Iowa Central Association, will meet at Winterset, Iowa, Nov. 2, 1883.

Z. G. COOLEY, Sec. pro tem.

The fall meeting of the New Jersey and Eastern Bee-Keepers' Association will be held in the city of New York, at the Cooper Union, on Wednesday, Nov. 7, 1883.

J. HASBROUCK, Sec.
Bound Brook, N. J.

The Lorain County Bee-Keepers' Association will meet at Oberlin, Ohio, on the last Tuesday in October, 30th.

O. J. TERRELL, Sec.

The next regular meeting of the Mahoning Valley Bee-Keepers' Association will be held at Newton Falls, O., on the first Saturday of November, 1883.

L. CARSON, Pres.
E. W. TURNER, Sec.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Do not let your numbers of the BEE JOURNAL for 1883 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

May we ask you, dear reader, to speak a good word for the BEE JOURNAL to neighbors who keep bees, and send on at least one new subscription with your own? Our premium, "Bees and Honey," in cloth, for one new subscriber to the Weekly, or two for the Monthly, besides your own subscription to either edition, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

ITALIAN BEES AND QUEENS.

Send for Price List to
D. B. BROWN, DES MOINES, IOWA.
42A111

BINGHAM SMOKERS.

I can sell the above Smokers at MANUFACTURERS' PRICES, by mail or express, at wholesale or retail. All the latest improvements, including THE CONQUEROR, and THE DOCTOR.

Send for my 32-page Illustrated Catalogue of Bee-Keepers' Supplies of every description.

ALFRED H. NEWMAN,
923 W. Madison, CHICAGO, ILL.

Sweet Clover

AND OTHER SEEDS.

Having a LARGE stock of SWEET CLOVER SEED, I can fill orders at 25c. per pound \$3.25 per peck, or \$12 per bushel.

Also, all other SEEDS for HONEY PLANTS,
ALFRED H. NEWMAN,
923 West Madison Street, Chicago, Ill.

THE BRITISH BEE JOURNAL
AND BEE-KEEPER'S ADVISER.

The BRITISH BEE JOURNAL is NOW published SEMI-MONTHLY, at Seven Shillings, per annum, and contains the best practical information for the time being, showing what to do, and when and how to do it. Rev. H. K. PEEL, Editor.

We send the Weekly AMERICAN BEE JOURNAL and the British Bee Journal, both for \$3.00 a year.

FLAT-BOTTOM
COMB FOUNDATION.

high side-walls, 4 to 16 square feet to the pound. Circular and samples free.

J. VAN DEUSEN & SONS,
Sole Manufacturers,
Sprout Brook, Mont. Co., N. Y.

Vandervort Comb Fdn. Mills,

Send for Samples & Reduced Price-List.

Bingham Smoker.

Please bear in mind that our patent covers all the hollows bee smokers that will burn sound wood.

Bingham & Hetherington,
ABRONIA, MICH.

\$72

A week made at home by the industrious. Best business now before the public. Capital not needed. We will start you. Men, women, boys and girls wanted everywhere to work for us. Now is the time. You can work in spare time, or give your whole time to the business. No other business will pay you nearly as well. No one can fail to make enormous pay by engaging at once. Costly outfit and terms free. Money made fast, easily and honorably. Address TRUE & Co., Augusta, Maine. 8A1Y

BARNES' PATENT
Foot Power Machinery

CIRCULAR AND

SCROLL SAWS.

Hand, Circular Rip Saws for general heavy and light ripping, Lathes, &c. These machines are especially adapted to **Hive Making**. It will pay every bee-keeper to send for our 48-page Illustrated Catalogue.

W. F. & JOHN BARNES,
No. 2017 Main street,
Rockford, Winnebago Co., Ill.

KEGS AND PAILS

FOR EXTRACTED HONEY.

These KEGS are designed to answer the popular demand for honey in small packages, and when compared with large barrels looking from 300 to 500 lbs. each, they are fully as cheap and often cheaper. They need no waxing, but should simply be thoroughly scalded with boiling water before used. The leakage so often occurring in the large hard-wood barrels can be entirely prevented by using this size of packages. Considering the cost and trouble of waxing, the loss of honey by leakage, and the ease with which these Kegs can be handled and shipped, with an actual saving in original cost, it is apparent to all that they are the best. Prices:

5 gallon Kegs, holding a trifle over 50 lbs.	40c
10 " " " " " " " " " "	100 lbs. ... 60c
15 " " " " " " " " " "	150 lbs. ... 80c

When 25 or more kegs are ordered at one time, a discount of 10 per cent. given on the above prices.

These new kegs are designed and manufactured with special reference to my experience and suggestions from those who have used the fish, lard and syrup kegs of last season. The staves are Norway Pine; the heads are Oak; and the hoops are Hickory, and, as will be noticed by the accompanying illustrations, they are well bound. If the heads are painted, I will guarantee these kegs not to leak. It is not essential to paint them, but I believe it will pay to do so.

These PAILS have a full cover and are excellent for selling honey in a home market, and after the honey is candied, they can be shipped anywhere. All sizes, except the smallest, have a bail or handle, and when emptied by the consumer will be found useful in every household.

Assorted samples of the four sizes put inside of one another as a nest, price, 50 cts. by express. The following are the prices in quantities:

	Per doz.	Per 100.
Gallon, holding 10 lbs. of honey	\$1.20...	\$12.00
Half Gal. " 5 " "	1.50...	9.00
Quart. " 2 1/2 " "	1.20...	7.00
Pint. " 1 1/4 " "	.75...	4.00

Send to Chicago, Ill., for sample of AMERICAN BEE JOURNAL Monthly, \$1 a year. Weekly, \$2.

THIS PAPER may be found on file at Geo. P. Rowell & Co.'s Newspaper Advertising Bureau (10 Spruce St.), where advertising contracts may be made for it in NEW YORK.

Weekly Bee Journal,

DEVOTED TO THE INTERESTS OF THE PRODUCERS OF HONEY.

VOL. XIX.

CHICAGO, ILL., OCTOBER 31, 1883.

No. 44.

THE AMERICAN
BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Home Markets for Honey.—It is encouraging to know that our advice about making home markets has been so generally followed. In the Secretary's report of the Northern Michigan Convention, on page 543, this language occurs: "Much more honey has been sold in our home markets than in previous years; nearly every one had found ready sale for all that had been produced." Yes; and by working the markets up there will be no trouble in selling ten times the amount that is now being produced. Let the good work go on.

Vice-President W. Z. Hutchinson reports the following arrangements: "The Michigan State Convention meets at the City Hall in Flint at 10 a. m., on Dec. 5, and continues in session two days. The President and Secretary may be found at the Dayton Hotel; excellent board can be obtained for \$1.00 per day."

Suddenly Killed.—Mr. Henry Alley writes as follows: Mr. E. F. Cassell, of Illinois City, Ill., a prominent and enthusiastic bee-keeper, was killed Oct. 6, while attempting to board a moving train of cars. Mr. Cassell has been one of my best customers for the past 10 years, and I regret his sudden, sad, and untimely death.

The feeder sent to our Museum by Mr. Alley, which we noticed on page 509, should have been called the "Locke Perfection Bee Feeder." Mr. Alley did not mention this at the time, and we innocently called it the "Alley's Feeder."

Drones from Worker Larvæ.—In the report of the Northern Michigan Convention, in this JOURNAL, on page 542, Messrs. Youngman and Trussell state that their bees have "reared drones and queens from worker eggs and larvæ." That queens can be reared, at will, from worker eggs and larvæ, is true, because both are females, but that drones, being males, may also be reared at the will of the bees, from worker eggs and larvæ, will be very generally disbelieved. Messrs. Youngman and Trussell should make further experiments, and report at the next meeting of the society, for, if we catch their meaning, their theory invalidates all the known facts in relation to the development of drones. But, perhaps, we do not get their idea, and hope to hear from them in the BEE JOURNAL concerning the matter. Careful investigation may reconcile it.

Surplus Honey Racks.—The Rev. A. Salisbury, of Camargo, Ill., sent one of his honey racks to be examined at the Convention, and then to be placed in our Museum—all of which has been done. He describes it as follows:

As I cannot be present at the Northwestern Convention of Bee-Keepers, I send one of my honey racks and a set of sections, showing my method of storing comb honey, and the ease with which the bees have access to all parts of the honey chamber. My rack is only the top story of the hive. I am not apprised that any one uses the same rack in the same way, except bee-keepers here who have adopted it this season. If you think it will throw any light on progressive bee-keeping, please show it to the friends at the Convention, after which place it with your collections of improvements.

A. SALISBURY.
Camargo, Ill., Oct. 13, 1883.

It must be understood that, should an advertiser desire to cancel an unexpired contract, he can do so only by paying regular rates for the number of insertions his advertisement has had.

Hilton's Apiary.—Mr. Geo. E. Hilton, Fremont, Mich., has sent us a view of his apiary, intended to be exhibited at the late Convention, but it did not come till after it closed. It is placed in our office album. He describes it as follows:

"As my business matters are assuming a shape that I shall not be able to consistently attend the Convention and see you all, as I should dearly love to, and had expected to, I mail you an 8x10 photograph of my home and the portion of my apiary that is not hidden by the house and trees. You will recognize me near the front row of hives; the person in the rear is a friend, and the parties in front of the dwelling, are my brother and his family, who are doing all they can to make home pleasant for me since the death of my dear wife, last May.

Mr. Moses Bailey, Winterset, Iowa, writes thus of our book "Bees and Honey," after he had read it: "I have perused your book entitled 'Bees and Honey; or the Management of an apiary for pleasure and profit,' and I find it to be 'just splendid.' Thanks for sending it to me." A cloth bound copy will be presented to any one sending one new subscriber for the Weekly for 1884, or two new subscribers for the Monthly for 1884.

Another Bee Paper is dead—the Illustrated *Bienen Zeitung*, published in German at Zurich, Switzerland. After struggling for 19 months for an existence, it succumbed to the inevitable.

Mr. J. S. Barb, Bristolville, O., sends us a plant for name. It is cleome—an excellent honey-producing plant.

To all new subscribers for the Weekly BEE JOURNAL who send us \$2.00 for 1884, we will send the remainder of this year free, from the time the subscription is received. So, the sooner they subscribe, the more numbers they will get free.

The Use of Honey as Food.

Dr. W. G. Phelps, in the *Practical Farmer*, gives the following on the use of honey, both as food and medicine:

In the minds of many persons there exists a prejudice against the ordinary use of honey as food. We hear it sometimes asserted that honey is an unwholesome sweet inducing colic, dyspepsia and various other disorders of the system. Such assertions are groundless. Honey in its purity is a God-given sweet, and, in its proper use, is conducive to health and strength. Indulged in immoderately, and only then at rare intervals, it may, like many other excellent articles of food, provoke an attack of colic or indigestion. Used however frequently and in connection with other food, it has a tendency to produce pure blood and give tone to the human system. Like all other sweets, it has also a tendency to fatten, and its use is said by medical writers to improve the beauty of the complexion. Sir John More, as early as 1707, was aware of the medicinal and beneficial effects of honey as a food, for he speaks as follows of it:

"The best helpeth to cure all of your diseases, and is the best little friend a man has in the world. Honey is of subtle parts, and therefore doth pierce as oil, and easily passeth the parts of the body. It openeth obstructions and cleareth the heart, and lights of those humors that fall from the head; it purgeth the foulness of the body, cureth phlegmatic matter and sharpness the stomach; it purgeth also those things that hurt the clearness of the eye, breedeth good blood, stirreth up the natural heat, and prolongeth life. It keepeth all things uncorrupt that are put into it, and is a sovereign medicament—both for outward and inward maladies, etc."

Experience with the use of honey in my own family, I believe, fully verifies Sir John's excellent opinion of this delicious substance. The question has been asked me by several of your readers: "Is not the comb taken into the stomach injurious?" I think I can safely answer, no! In other articles of food we often take into the stomach similar indigestible substances without injury, and often with benefit. Who, for instance, takes the trouble to seed every grape pulp eaten, or stone every cherry? These indigestible articles pass through the body without in the least injuring it. So with wax, as eaten in moderation, in comb honey. The uses to which honey can be put in cooking and in medicine, indicate it as of prime importance in the economy of life. Used instead of sugar for preserving raspberries and other fruits, I know of nothing its equal, as to many such compounds it imparts a peculiarly delicious flavor. For sore throats, ulcers of the mouth, and many other diseases honey forms a valuable remedy. To the rare individual for whom the temperate use of honey may produce functional disorders, I would say try heating honey before using it, and

see if all such trouble is not remedied. Honey can really no longer be considered one of the mere luxuries of life. For the poor, it has become a cheap and wholesome substitute for the too frequently impure butter. Millions of pounds are to-day consumed by rich and poor alike, when 10 or 15 years since, but a few thousands were used. The severe stab which the manufacturer of the miserable glucose has received is due to a great extent to the production of extracted honey. This being the pure article, and produced, even at a profit, for 10 cents per pound, has virtually gained the mastery in competition with the above falsely so named "cheap sweet." Eat pure honey therefore, so that you may grow strong and handsome, fat and jolly, and—best of all—healthy and wise.

Honey Crop in Saginaw Co., Mich.

A correspondent in the Saginaw Co., Mich., *Evening News* of last Thursday, contains the following concerning the honey crop of that section, and as that is the home of Dr. L. C. Whiting, Heatherington & Wellington and Mr. James Ure, it will interest our readers to know how the "sweet work" progresses there:

I have made inquiries of bee-keepers, and made a careful estimate of the yield of honey in Saginaw County, and find that this year's product is but one-fourth of what it was last year. The season opened with promising prospect, bees increased rapidly in numbers and swarmed about the close of the white clover blossom. The new swarms have gathered no honey, and must be fed, or they will starve, during the winter. Some bee-keepers have already bought honey and sugar in equal parts and fed their bees for winter.

It has been a question with some whether it would be economy to shake the bees out of the combs and save what stores they have, or buy \$3 worth of feed for each colony, to feed them, and run the risk of losing them after all, during the winter. All colonies are light in bees, whether they have stores or not, but this is especially the case with those with little or no honey. This is usually an unfavorable condition for a cold winter. The best that can now be done is to see that they have plenty of stores, and are packed so as to keep out the cold, or placed in a cellar that does not freeze.

Mr. J. D. Enas writes that the name given in his communication on page 505 of the BEE JOURNAL for Oct. 10, as "Mr. M. Bragg," should be Mr. M. Bray. Of course it was an oversight of the printer.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

We have received a copy of the *Swine Breeders' Manual*, or how to breed and manage improved swine, published by P. M. Springer, Springfield, Ill., at 25 cents. The *Swine Breeders' Manual* presents the subject in some of its details in a plain, brief way. Even those who have never kept any other than common hogs, may find in it much that will aid them to secure better results than are usually realized in the rearing of ordinary stock, and which may lead them to a trial for themselves of improved swine.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
Monday, 10 a. m., Oct. 29, 1893. }

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The demand for honey is extremely slow, and our commission houses are too well supplied to expect anything else. Prices rule low. Manufacturers complain of slow business. Extracted honey brings 7¢, on arrival, 1 have bought for less. Comb honey in good order, 12¢/15. BEESWAX—Good yellow beeswax brings 27¢/28 cts.; offerings few.

CHAS. F. MUTH.

NEW YORK.

HONEY—White clover and basswood in 1 and 2 lb. sections, 17¢/21¢. Dark and second quality, 14¢/15¢; extracted white clover in kegs and barrels, 9¢/10¢; dark, 8¢.

BEESWAX—Prime yellow, 27¢/29¢.

H. K. & F. B. THURBER & Co.

CHICAGO.

HONEY—The demand for honey is good. Choice 1 lb. sections of white comb, well filled, brings 18¢/20¢; 1½ to 2 lb. sections, 16¢/18¢. No demand for dark comb honey. Extracted honey is bringing 8¢/10¢ per pound, according to body, color and flavor.

BEESWAX—Prime yellow, 33¢; medium, 28¢/30. R. A. BERNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—There is a fair jobbing trade. Offerings are not large. Choice quantities command extreme figures. White to extra white comb, 16¢/20¢; dark to good, 10¢/13¢; extracted, choice to extra white, 8¢/9¢; dark and candied, 6¢/7¢.

BEESWAX—Wholesale, 27¢/28¢.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Choice in better demand, but unchanged. Sales chiefly in a small way. We quote strained and extracted at 6½¢/7¢. Comb at 12½¢/14¢; choice, in fancy packages, higher.

BEESWAX—Readily salable at 26¢/27 for choice. W. T. ANDERSON & Co., 104 N. 3d Street.

CLEVELAND.

HONEY—Comes very slowly and sells as fast as it comes at 16¢/18¢ for best white in 1 lb. sections, and 17¢/18¢ for 2 lb. sections. Second quality is very slow. Extracted usually sells very slowly in our market.

BEESWAX—None in Market. A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—We quote extracted honey at 10¢/11¢, with a good demand. We have sold easily four times as much extracted as we ever did before.

BEESWAX—We have none to quote. BLAKE & RIPLEY, 57 Chatham Street.

KANSAS CITY, MO.

HONEY—Market continues active, and everything in the way of comb honey is taken up on arrival at 16¢/18¢ for choice 1 and 2 lb. sections. Extracted honey is in light demand, though some good sales were made last week at a concession, 8¢/9¢; latter price for strictly choice honey in 5 gallon square tin cans with screw top, which is a desirable shape for this market.

JEROME TWICHELL, 536 Delaware Street.

CORRESPONDENCE

For the American Bee Journal.

My Report for 1883.

G. M. DOOLITTLE.

By turning to page 248, of the present volume of the BEE JOURNAL, the reader will there find in what condition my bees were on May 2 of this year. About this time the weather began to warm up, and new flowers to produce pollen, so that brood soon began to be reared quite abundantly. About May 25, apple blossoms opened; but, as it rained the most of the time, little honey was obtained, so that most of the brood was reared from old honey still left in the hive. White clover bloomed very profusely, but as it was cold and wet all the while, the bees did not get a living, and, to keep them in good condition to gather honey when it came, I fed them from 200 to 300 pounds of old honey, which I had on hand. Whitewood, sunac and wild mustard came and went, but yielded no honey, and, although there was a merry hum in the locust trees while in bloom, when it did not rain, still scarcely enough honey was obtained to keep up brood-rearing, even while the trees were white with blossoms. It was rain, rain all the while, till every one longed for a few days of dry weather.

On July 16, the basswood blossoms opened, and, although, it still rained nearly every day, yet between the showers the bees worked as I never saw bees work before. While the blossoms to most other flowers are so formed as to catch the rain when it falls, and thus dilute the nectar in them, or wash it all away, the basswood blossom stands like an inverted dish, causing the rain drops to glide off without touching the nectar, thus allowing this flower to afford the bee an opportunity to secure the coveted sweet, even in a rainy time. To this peculiarity of the basswood flowers I owe most of my honey crop, for it rained nearly every day while the basswood was in bloom.

On July 23, it became cold, so that for three days scarcely a bee left the hives, and the bee yard was nearly as silent as in winter. About noon on the 27th, it warmed up enough so that the bees again went to work, and for the next week they labored assiduously when it did not rain. At this time the bloom was gone near the apiary, but on the hills, some six miles distant, it was still in its prime. As no long rainy spell had made a "gap" in the flowers, the bees followed up, as the flowers receded, till this distance was reached, while a long rain of three days would have allowed the bloom to have failed at a point two miles or so from home, for a mile or so in width, over which the bees would not have passed to find the flowers which were in bloom beyond. Thus

fortunate, the bees still labored five or six days on the hill tops which helped them to finish up many sections which would otherwise have been left unfinished.

Many claim that bees do not work so far from home, or if they do, it is of little or no advantage, but I could see but little if any difference as to the gain made at this time, when compared with the week previous.

But, to return, with Aug. 13, the supply on the hills seemed to fail, and when I opened the hive on the 14th, I soon saw that the honey harvest was over, as robber-begins to appear. For the sixth time, in succession, buckwheat failed to give any honey, and the season of 1883 passed without a single pound of surplus except from basswood.

By loss in wintering, as given on page 248, and sale of bees and early queens, my stock was reduced to 55 colonies, 40 of which were fairly good and the remaining 15 were from weak to very weak. I decided to work the 40 good ones for honey, and the 15 weak ones were to be devoted to queen-rearing. By footing up the result, I find that the 40 worked for honey, gave a surplus in comb honey of 2,388 pounds, and of extracted honey 1,922 pounds, making 4,310 pounds in all, or 107 $\frac{1}{2}$ pounds, as the average yield per colony, spring count.

My comb honey was sold at 16 cents per pound, delivered at our nearest railroad station to a buyer for the Boston market, and my extracted is selling readily at 10 cents. By adding the sales of bees and queens to the product of the honey, and deducting expenses, I find I have \$1,021.30 left as the net proceeds from the bees.

As I have 80 colonies of bees at the time of the writing, in as good condition as were the 80 a year ago, this gives me a salary of \$1,021.30 for caring for 80 colonies of bees one year, during which there was no honey yield, except from basswood.

I am frequently asked why I do not keep more bees, and why I do not attend conventions, etc. I wish here to reply to all, that I have a beloved father who is entirely helpless, from "creeping palsy," who depends upon me (an only son) to live and care for him. So long as he lives my duty is plainly at home, which reason is sufficient excuse for a small number of bees kept, and a close confinement at home.

Borodino, N. Y.

For the American Bee Journal.

Northern Michigan Convention.

The Northern Michigan Bee-Keepers' Association met at Sheridan, Mich., at 10 a. m. Called to order by the President, Geo. W. Stanton. The proceedings of the last meeting were read and approved. The roll of members was called, and a fair number found to be present. The meeting adjourned until 1 p. m.

At 1 p. m. the meeting was called to order by the President. The Secretary's and Treasurer's reports were read and approved. The enrollment

of members was then made, which numbered 29.

The reports of the standing committees were then in order. The First Vice-President, F. A. Palmer, reported his success in bee-keeping as follows: In 1880, I bought 2 colonies, and, in May, I brought them home, and that season doubled them in number and took 135 pounds of honey, 35 of which was comb, and the balance extracted. I wintered them in Roop's winter hive, packed in sawdust, successfully. In 1881, I increased to 12 colonies, and took 775 pounds of honey, mostly extracted, which I sold for \$99.27. I wintered again successfully as before, on the summer stands, and in 1882, I increased to 30 colonies, and took out one ton of honey, 100 pounds of which was comb, and the balance extracted. In the fall, owing to a pressure of official duties, I neglected to prepare my bees for winter, and lost all but one colony; I have increased to two, this summer, and shall buy more in the spring.

Our Fifth Vice-President, Miss F. A. Bellamy, of Ionia, makes the following report: "I received notice from our Secretary, as I was one of the officers, that I should make a report of my work this season. This is my third year in the apiary. I consider myself a novice. I have learned much, but I think I have very much more yet to learn. We began this spring with 13 colonies; now we have 40 strong colonies in good condition for winter, and have secured 2,450 pounds of honey, besides what our family have used on the table; that I have no account of. We have some neighbors that keep a few colonies, but with a few exceptions they are doing but very little with them. I have solicited their attendance at this meeting."

No other Vice-Presidents being present, we listened to the President's address, giving an account of his summer's work in the bee yard. Not meeting with the best success, he did not care to have it appear in print. He has 48 colonies, mostly strong; 8 or 10 may need help; his bees were not yet prepared for winter.

The following subjects were then discussed: "The cause and disposal of fertile workers;" and "The introduction of fertile queens to colonies that have just swarmed." Thirty-six bee-keepers were then present. The subject of "Foul Brood" was brought up, and enlisted a lively interest, as two or more cases were reported as existing in the county, having been brought here from Howell, Mich.; the facts of which were well known to Mr. S. J. Youngman, of Lake View, and W. W. Trussel, of Colby. A committee of three were appointed to investigate the same, and if it be found that foul brood existed in our county, to take the necessary steps to destroy the same. The President appointed the following members as a committee: S. J. Youngman, Lake View; W. W. Trussel, Colby; H. M. Roop, Carson City.

The subject of "Comb Foundation" was then taken up, and the different makes and qualities discussed; each giving their preference to some par-

ticular make, but the general impression was; that made on the Dunham machine by Dabant, was as good as any made. No one favored the use of old foundation carried over from the previous year, but would advise it being melted and made over. Some experiments made by Mrs. A. M. Sanders, during the past season, showed great advantage in favor of foundation made by Dadant & Son. Many thought much of the difference was owing to the material used as a lubricator in its manufacture; others in the manufacture of the wax; whether it be rendered with a wax extractor by the process of steam, or the old way of the wash boiler and rag process. Mr. W. O. Burk being present, who is engaged in the manufacture of foundation, says he has seen no wax that was burned that was gotten out with the wax extractor.

The subject of "Robber Bees" was discussed, as to the process of preventing and breaking up robbery. Many devices were given.

"The care of empty combs" was then taken up. No device was given that had been successful except by making a large box or cupboard, closely made, and by placing the combs therein and fumigating with sulphur.

"The process of rearing queens" was then taken up. Mrs. A. M. Sanders practices Doolittle's plan. Much favor was shown for the plan as given by Mr. J. H. Robertson, and the reading of this plan was called for, and the Secretary read the same, as given last year, from the minutes of the last convention.

S. J. Youngman gave us his plan of removing the queen and all unsealed brood, and after twelve hours he took a card of drone comb and cut it on a circle, then selecting the larvae from a colony from which he wished to rear queens, taking a strip of the same and cutting off the cells one-half or two-thirds their length, and with wax or glue fasten it on the under edge of the comb, cut on a circle, and with a match or quill remove every other one of the young larvae, leaving sufficient room to cut the queen-cells from the combs when ready to hatch, and placing them in a nuclei. In this way he has increased from 12 colonies to 60, the present season, and extracted 800 pounds of honey; 3 colonies went to the woods, and he has sold 12 queens.

"Drone brood, how disposed of," was then discussed, and it was unanimously approved that it should be well pruned out with a knife, leaving a reasonable amount in each hive, and in black or hybrid colonies their own brood should be all removed and other substituted from more desirable colonies.

"The different methods of feeding" was then discussed. No new way being devised, many of the old ways being satisfactory; but all agreed that fall feeding should be done early to prevent too late brood-rearing. If feeding must be done, let it be done as early as possible.

W. W. Trussell says he has had a colony that had no drone eggs or

drones, and the queen was destroyed, and the bees reared drones and queens from worker eggs.

Mr. Youngman says he has had queens, drones and worker cells all from the same larvae; they were all capped, but he does not know what hatched from them.

During the above session upwards of 60 persons were present. Adjourned to 7 p. m.

The evening session was called at 7 p. m., with all the officers present. The first subject taken up, was the "Best method of increase." There was a diversity of opinion, but much favor was shown toward the plan given by Mr. Youngman, of starting early a nucleus with one or two frames of brood, and adding others as fast as the bees can care for them, by taking one or two frames from strong colonies when they could spare them, shaking the bees off at the old hive. Messrs. Wood, Benham and others favored artificial swarming.

A. L. Entricon had wintered drones and had queens fertilized very early, at a time when he thinks no other drones were in the yard; the queen was reared in the colony in which the drones were.

"The use of old combs; how long to be used." All admit that very old combs will produce smaller bees, but no one was able to tell whether those bees would ever attain full size after hatching. Mr. Youngman would not discard old combs, if perfect, for 10 or 15 years use.

Mr. Goodno approves of their use as long as perfect, as they are much better to ship bees in. No time could be agreed upon as to when to discard them.

The subject of "Bee pasturage" was then discussed. Much was said in favor of Alsike clover, the seed of which was furnished free by some of the members to their neighbors, who would sow it; also buckwheat in the same way, both of which could not be too highly spoken of. Other valuable bee plants were spoken of, which were of value besides for bees. Among them the English mustard and leasel.

The Secretary had placed upon exhibition seeds of the Rocky Mountain bee plant, borage, English mustard, sweet clover and figwort, which he freely distributed among the members. He was favorably impressed with the cultivation of all of them, placing them in waste places where now ragweed and dog-fennel occupy the ground. The cultivation of honey plants seems more necessary in older countries. The choice for a bee location is surely where it is just being cleared up, where raspberries, honeysuckle, fireweed, asters, goldenrod, Spanish needle and the many wild flowers have not been subdued.

Adjourned until 9 a. m.

Wednesday, Oct. 10, at 9 a. m., the convention was called to order by President Geo. W. Stanton.

"The use of the telephone in the bee-yard" was discussed, and much valuable information was given by F. A. Palmer, of McBride's, who made the discovery as to its use two years ago, and communicated the facts to

A. I. Root, who now sells the instruments.

Marketing honey was a topic of much interest, and showed that much more honey had been sold in our home markets than in previous years; nearly every one had found ready sale for all they had produced.

The ladies present gave details of the use they had made of honey in preserving fruits, especially blackberries, and much preferred it to sugar. Some of their neighbors having bought honey in preference to sugar, considering it cheaper. The greater part of the honey produced by those present being extracted, and the price varying from 10 cents to 14 cents at their doors, and when placed in the stores for sale, had been put in jelly cups, one pint, one quart, and two quart fruit jars; and where it was to be retailed, Mr. L. S. Benham, of Alma, had had calls for it put up in large sized jugs, letting it candy in the jugs, and when it reached its place of destination, it could be placed in a pan of hot water on the stove to liquefy, and make it convenient to retail.

Mr. Palmer preferred Japan pails holding 50 pounds.

Mr. Youngman was favorable to canvassing the county, and if necessary sell in small quantities, and afterwards make larger sales in consequence, and when they would not at first buy, leave a sample, and in that way make new customers.

The Secretary thinks, no doubt, that we would receive ample reward for the expense of buying the pamphlet on "Honey as Food and Medicine," in lots of 500 or 1,000, and distribute them fully, while canvassing, as Mr. Youngman suggests.

Mr. Benham said his experience was very unsatisfactory, in shipping honey in tin cans without cooping or crating.

The comb honey reported by members present had all been sold at from 15 to 25 cents per pound. A short distance showing a wide variation in prices in both extracted and comb honey, which is hoped will be regulated in a few years to that of a uniform price.

The subject of "Wintering" was the all-absorbing topic, and there was no one present but had something to say. All of the old plans and theories were revived, and verbal reports made of past experiences; many of which were sad, but still hopeful to secure the patent for wintering bees. Many favorable reports were given on experiments tried last year in burying them in trenches under ground. Others were inclined to try Mr. Dennison's plan, who places them in cellars, removing the bottom-board and setting the hives on scantlings so that dead bees can drop away from the bottom of the hives and frames. Mr. Dennison has been very successful in wintering in that way. The subject was thoroughly discussed, and no one could go away without gaining some new ideas, and all will be left to figure out its solution.

The officers for the ensuing year were elected as follows: President,

S. J. Youngman, of Lake View; Secretary and Treasurer, F. A. Palmer, of McBride's, 1st Vice-President, L. S. Benham, of Alma; 2d Vice-President, Edward Hunt, of Sheridan; 3d Vice-President, L. L. Bissell, of Lake View; 4th Vice-President, Mrs. A. M. Sanders, of Sheridan; 5th Vice-President, J. H. Robertson, of Pewamo.

The next annual convention will be held at Alma, Gratiot County, Mich., on the 2d Tuesday and Wednesday of October, 1884.

Adjourned until 1 p. m.

The Secretary suggested that a semi-annual convention be held, during the working season, at some bee-keeper's apiary, accessible by all, that we may get practical ideas, and that the same be made a basket picnic, and all have a good time. The suggestion was approved, and the President, Secretary, Treasurer, and 1st Vice-President were made a committee to name the time and issue the call for the basket picnic convention. Miss F. A. Bellamy made the request that the gathering be held at her home near Ionia, which was cheerfully agreed to.

There being a little time before the trains were due, the subject of hives and frames was discussed, there being 722 colonies represented by members present, of which 539 were square or deep frames, and 183 Langstroth frames. It showed a preference for the square or deep frame. Mrs. A. M. Sanders could say nothing against the Langstroth frame, though she had both the shallow and the square frames, but considered the square frame the most convenient to handle. Bees wintered well, and possibly better in the shallow frame than in the square, last winter. Mr. Goodno's experience had been about the same; like all other discussions upon this subject, all did not agree.

There was placed upon exhibition at this convention an improved winter bee hive for the shallow frame, by Wm. O. Burk, of Crystal, which attracted much attention, and met with favor. He also had a simple though convenient device for fastening foundation in sections of his own make. The Secretary also placed upon the table the eighth edition of Prof. Cook's Manual, Thos. G. Newman's "Apiary Register" for 200 colonies, a supply of Weekly and Monthly BEE JOURNALS, and general catalogues of literature for the apiary, which was freely distributed. Others placed copies of A. I. Root's A B C of Bee-Culture, Quimby's New Bee-Keeping by L. C. Root, A. J. King's Text Book, and some fine comb honey by E. S. Collins, of Cedar Lake. This feature of the convention was interesting and instructive, but it is hoped a larger exhibit will be shown at our next convention.

The list of colonies with size of frames was as follows: L. L. Bissell, Lake View, 23 colonies in Langstroth frames; F. A. Palmer, McBride's, 2 colonies in 10x10 frames; S. J. Youngman, Lake View, 65 colonies in Langstroth frames; F. O. Johnson, Chadwick, 32 colonies in 9x10 frames; A. L. Entricon, Westville, 30 colonies in

10x12 $\frac{3}{4}$ frames; N. Kendall, McBride's, 13 colonies in 10x10 frames; E. E. Thayer, 4 colonies in 10x12 frames; H. Peck, Saranac, 12 colonies in 11x-11 $\frac{1}{4}$ frames; Geo. W. Stanton, Sheridan, 48 colonies in 10x12 frames; O. R. Goodno, Carson City, 46 colonies in 10x10 frames, and 16 colonies in Langstroth frames; Mrs. A. M. Sanders, Sheridan, 20 colonies in Langstroth frames, and 44 colonies in 10x12 frames; Mrs. Francis Miller, Sheridan, 6 colonies in 10x12 frames; Miss F. A. Bellamy, Ionia, 40 colonies in Langstroth frames; Wm. O. Burk, Crystal, 3 colonies in Langstroth frames and 16 colonies in 10x10 frames; Mrs. A. Bradley, Sheridan, 7 colonies in 10x12 frames; W. M. Penny, Shilo, 39 colonies in 9 $\frac{1}{2}$ x10 frames; E. S. Collins, Cedar Lake, 12 colonies in 10x10 frames; O. F. Mason, Crystal, 12 colonies in 10x10 frames; J. W. Mitchell, Carson City, 3 colonies in 10x10 frames, and 16 colonies in Langstroth frames; W. W. Trussell, Colby, 23 colonies in 10x10 frames; V. Hallett, Colby, 12 colonies in 10x10 frames; M. Foster, Sheridan, 6 colonies in 10x10 frames; L. S. Benham, Alma, 81 colonies in 10x10 frames; Chas. Cross, Carson City, 63 colonies in 10x10 frames; D. A. McLean, Stanton, 6 colonies in 10x10 frames; Mrs. G. L. Lean, Sheridan, 12 colonies in 10x12 frames.

Total, 539 in square or deep frames, and 183 in Langstroth frames.

A vote of thanks was tendered to Mr. Stone for the gratuitous use of his hall; also a vote of thanks to Geo. W. Stanton, E. Hunt, Mrs. A. M. Sanders, E. E. Thayer, and others, for generous hospitality.

A vote of thanks was extended to the retiring Secretary for his service for the past six years, and for the interest he has always manifested in the welfare of the association. Adjourned.

ORRIN R. GOODNO.

Retiring Sec.

For the American Bee Journal.

Labeling Packages of Honey.

W. Z. HUTCHINSON.

Of late quite a number have tried to out-do somebody else in getting up showy honey labels. Such enterprise is commendable, but the honey label has not yet been invented. I fear the inventors are working in the wrong direction. Take a clean, smooth, white section box, fill it with snowy-white tempting comb honey. There; does that need a fancy label? Will a showy label add to its beauty? Will it not rather detract? Is a beautiful woman more beautiful when overdressed with gaudy attire? Does a rich, ripe strawberry need a strip of colored paper wrapped around it before it is fit for market? If not, then why desecrate the virgin purity of our white combs of honey by pasting around them gaudy labels? Ah, yes, says one, but these labels hide the propolis, mildewed sections, and unsightly holes left by the bees at the corners. Very true, but would it not be better to use smooth, white, well-seasoned sections, pursue such a

method of management that the sections will be well filled, scrape off all propolis, and then the honey would be beautiful in its simplicity.

Hundreds of people, upon seeing my exhibit of comb honey at the State Fair, exclaimed: "That is the finest lot of honey that I ever saw!" That the honey was nice, is a fact, but there was an added attention of which, perhaps, no one thought, and that is, the honey was stored in smooth, white sections, crated in crates made from smooth, white lumber, and the reflection of the light from the smooth white surface of the surrounding wood, gave to the honey an added whiteness. There was an entire absence of labels, and, as the cases were piled up, tier upon tier, in the form of a pyramid, the exhibition was grand and beautiful in its simplicity.

Pure, white comb honey cannot be adorned, but if any producer desires to have consumers know whose honey they are eating, and hopes thereby to gain fame and sell much honey, let him use a small, neat, unobtrusive rubber stamp bearing his name and address, and stamp each section before putting it upon the hive.

How about extracted honey? Well, if it is put in glass, and kept in a liquid state, what is the first thing that a would-be purchaser does? He holds the package up to the light and exclaims: "Ah, how fine!" That is, he does if the package is not covered with a gaudy label, if so, how can he? A neat, attractive, but small label is the best for glass packages. When honey is put up in tin, there is some excuse for adornment by the way of labels, but even then I do not approve of highly colored, flaming labels; they give to the honey a tin-can, bar-soap, groceryified appearance. Let the packers of fish, fruit, and vegetables adorn their wares with gaudy "chromos" if they please, but the product of the apiary requires nothing of the kind. It is beautiful in itself. "Beauty unadorned is most adorned."

Rogersville, Mich.

For the American Bee Journal.

Queen Cages, Introducing, etc.

G. W. DEMAREE.

While reading Mr. Doolittle's article on page 511, Weekly Bee Journal, concerning "sending queens by mail," it occurred to me that those persons who have received queens from my apiary, through the mails, in the past season, and have read Mr. Doolittle's description of the cage used by him, will be puzzled to know which has stolen "tother's thunder," Mr. D. or myself. The cage described by Mr. D. is "point blank" the same in every substantial feature as the one I have used for sending queens by mail for more than a year past. In September, 1882, I sent a queen and her suite of bees to Rev. E. L. Briggs, of Iowa, and he returned the cage to me with a queen and her escort from his apiary without replenishing the

food in the cage, as I understood it from him, and both queens and bees were found in the very best condition when reaching the end of their journeys.

I, at first, used a tin tube in the form of a miniature barrel, which was filled with the soft candy and inserted in the transverse hole in the cage, and the "lung hole" in the tin barrel was brought in line with the opening between the queen's apartment and the transverse food apartment. My idea for using the tin barrel was to prevent the soft wood block from absorbing the moisture of the candy, and to exclude the air as much as possible from the same.

After testing this method of provisioning the cage to my own satisfaction, finding it far superior to the old plan of boring one or two shallow holes in the top of the block, leaving the food exposed to the air, I conceived the idea of waxing the transverse hole and thus secure all the advantages of the tin tube without its extra expense and trouble.

I wax the food apartment of the cages by means of a "swab," which nearly fills the hole. This is dipped in hot wax and inserted into the hole and passed closely to every part, thus filling completely the pores of the wood. After the candy is passed into the hole, the latter is corked tightly with a common bottle cork, which is cut off, smooth with the block.

A few words about soft candy for provisioning queen cages will not be considered improper here. Doubtless some will remember that several years ago I experimented considerably with a candy made by mixing powdered sugar with a thin paste made of hot water and flour; my idea was that the paste would give adhesiveness to the mixture, and the "rawness" of the sugar would give the moisture. This candy proving to be seriously defective, though better than boiled candy, I commenced experimenting with candying honey. A good article of white clover, as thoroughly granulated as I could get it, was enclosed in a thin cloth bag and washed in cold water until most of the glucose substance was separated from the mass, after which the residue was tempered with granulated sugar until it was quite firm and stiff. I found this a success in every respect. I used this mixture before I ever heard of Mr. Good's mixture of unprepared honey and powdered sugar, and for long confinement, I believe it has no equal as a cage food to this day.

Why did I not give it to the public? Well, because I have "went off half cocked" so often in the past, that I have learned "great prudence," eh! But to return to the cage subject. I believe it an injury to a queen to startle her by pounding on the cage with the hammer, in the process of finishing it, after the queen is put into it. Bees are quite susceptible of being alarmed, and a "big scare" is doubtless very detrimental to them. On several occasions I have seen symptoms of dysentery in bees, that could be traced to no other cause than from the effects of a "big scare."

Therefore, I handle the cages which contain queens gently at the start, till the queen and her escort get over the first excitement consequent on their captivity. The cage should be entirely completed, ready for the mail bag, excepting the paper and twine, before the queen is hurried into it.

This is easily done by having a little side door to the cage through which the queen and bees will crawl very readily if the cage is held in such a position as to bring the entrance or door at the lowest part of the cage, and show the light above. The door can be closed by means of any simple device. But as I use this cage in preference to any other as an introducing cage, I employ for a shutter to the entrance, a little tin slide, which, when in an erect position, projects a half inch or more above the bottom of the cage when the wire cloth side is down; this tin slide is kept bent down flat with the bottom, so as to be out of the way excepting when the cage is employed to introduce the queen, in which case the tin projection is made to stand erect as first described.

To introduce a queen by means of this cage, the cage is placed, wire cloth down, on the frames in the usual way, so as to be between the quilt and tops of the frames; a small incision in the quilt permits the tin slide to "stick up" through the quilt, thus arranged the hive is closed.

The following day I open the hive, using care not to jar it, turn back the quilt until I can see what the bees are doing about the cage, if they are "balling" the cage. I close up the hive and let them vent their spleen on wood and wire until in a better mood. In this way I take a peep at them once or twice a day until I find the bees moving calmly about the cage just as others may be seen moving about the tops of the frames. When this condition of things is present, I close up the hive, feeling perfectly satisfied that all will go well.

Any time, after giving the bees a little time to become quiet, I open the hive with all the care possible, place my thumb on the cage to hold it firmly, and with the other hand draw out the slide and close up the hive.

After trying every feasible method which has been suggested by writers on the subject of introducing queens, I am glad to go back to the method above described, which I have tested thoroughly for three or four years past. It would be interesting reading were I to point out the serious defects in nine-tenths of the methods employed to introduce queens, but I have not the space to do it here.

Notwithstanding the severe drought which cut off nearly all our fall flowers, my bees got some honey from goldenrod, an unusual occurrence in my location, and but little from hydropiper, from whence our main fall supply generally comes. My bees are in surprisingly good condition for winter. Up to this writing, Oct. 20, we have had no frost to injure the tenderest plants, and bountiful rains during the last four weeks, has given us grass enough to winter all our farm animals if the winter should be an open one.

Christiansburg, Ky.

For the American Bee Journal.

Eight Frame Hive for Comb Honey.

GEORGE GRIMM.

I am slightly exercised at the idea that this controversy will eventually "improvish" me, and prove that which I have long accepted as a fact, to be but a "myth." Now, James, please don't! Remember how, two years ago, I listened so attentively to your eulogies on nature, etc., and how earnestly I helped you to destroy the last vestige of that chicken-pie we had for dinner! But if you must, well, then—but hold! I have got something to tell first: There is nothing in the whole AMERICAN BEE JOURNAL that interests me more than discussions on the wintering problem; and though I would not for the world come between the cross-fire of two such sharpshooters as Mr. Heddon and Dr. Tinker, yet I like to stand behind the fence and see the fun.

Yesterday I got out my old volumes of bee journals to see how much progress we have made in the last few years, and this is what I found in the *American Bee Gazette* under date of April 15, 1866: "How to winter bees best in a cold climate, is one of the questions that has never been decided and probably never will be, as different apiarists have different methods of wintering them; but a few principles can be laid down that all will admit to be correct, as follows:

1. To keep them in an even temperature, cool, but not cold enough to cause the dampness of hives to congeal to frost.

2. To keep them as quiet as possible, and if placed in a room or winter bee house, to be in complete darkness.

3. To afford them a free ventilation of pure air under all circumstances."

Will some one please answer how much more we have learned since then!

In searching through those old volumes, I found on a piece of old yellow paper, an article from my father's pen, which apparently has never been published, and as it bears somewhat upon this wintering question, and on the 8 and 10-frame Langstroth hive, I will copy it verbatim:

Jefferson, Wis., April, 1870.

"LANGSTROTH VS. SQUARE HIVES. —I use three kinds of movable comb hives in my apiary. One is the common one-story Langstroth hive, 10x14-x18 with 10 frames; the second is 10x12x18 with 8 frames; the third is 11½x13½x16 with 9 frames. I have used these hives for the last four years, but got up only hives of the second and third kind the last three seasons. I put my surplus honey boxes mostly directly on top of the frames, and let most of my hives swarm naturally. Now, for the result: From No. 1, swarms came averaging not as often as from No. 2 and No. 3, and I got, so far, but little surplus honey. The colonies in those hives, however, are usually very strong and heavy in the fall. From No. 2 (the 8-frame hive) I get more swarms than from No. 1, and nearly all my surplus honey. From No. 3 I get more swarms than

from either of the two other kinds, but had not a single pound of surplus honey last season from 66 good colonies, and about 25 had not swarmed. The colonies in those hives are usually very strong and heavy in the fall. Bees in those three different kinds of hives winter well if wintered in the cellar, better than in common box hives, all of which had more or less moldy combs this spring. All things considered, I prefer hive No. 2, and so much am I convinced of its superiority, that I made 300 of them last winter, and am now making 360 more; while I make but 36 hives of No. 3 this season."

One line is here skipped, then comes the following without date, but apparently written soon after:

"From Nov. 9 to 12, last, fall, I stored away my 365 colonies of bees in my home apiary into the cellar and they remained there till the 26th of March, when I commenced taking them out. I finished on the 31st; only 3 of the 365 colonies had died, and they had been over-looked last summer, having been queenless ever since swarming. Of the 362, only 3 appeared to be queenless."

This is the best success I ever had in wintering bees. The bees in my outside apiaries are yet in their winter quarters.

A. GRIMM.

Let me add, that if, as Mr. Heddon claims my father was very successful in wintering bees, and I have not a doubt on that point, then it is an established fact that he was successful while using the 8-frame Langstroth hive; because at the time when he kept the "large numbers of colonies" he had discarded nearly all other styles except the 8-frame Langstroth.

Jefferson, Wis., Oct. 12, 1883.

For the American Bee Journal.

The Trial of the Small Sections.

DR. G. L. TINKER.

After much delay, I am able to make a report on the use of the small sections. We had so much cold and wet weather in June and July, followed by a severe drought in August, that the amount of surplus honey is below the average in this locality. In considering the experiments here given, these facts should be taken into account.

The small section, $3\frac{3}{4} \times 3\frac{3}{4} \times 1\frac{1}{2}$, was used on 14 colonies on an improved plan, the principle involved being, continuous passage ways and continuous combs. The plan proved to be a complete success, and might have been tested upon one hive as well as on the 14. I also found that the use of sections without separators could be made, with a little care in the management, entirely satisfactory. But the use of separators with a small section will be found unprofitable on account of the extra labor and expense involved.

When it was seen that the half-pound section without separators would be a success, one colony (a new swarm) was tried on the same plan with a section of larger size, $4\frac{3}{8} \times 4\frac{3}{8} \times$

$1\frac{1}{2}$. Twelve of these were nicely capped over, and their weight found to average about 14 ounces, or not far from the average weight of the $1\frac{1}{4} \times 4\frac{1}{2} \times 2$ section used with separators. The plan worked as well with this size as with the smaller. Other sizes larger were made, as samples, but they looked to be so much like a frame that the smaller size was adopted. With this size of section operated on my new surplus arrangement, it is believed that the utmost capacity of comb honey production by a colony of bees can be easily attained. But even with the smaller size of section, operated on the new plan, it is thought that considerably more honey can be obtained than by any other plan of section arrangement now in use, and with less labor and less trouble!

The tests were as follows: On seven hives the small section was tried with wood separators sawed exceedingly smooth out of white poplar. The bees entered the sections readily enough, but not to cluster and begin comb building for several days, and then the progress was slow. In each case the honey was principally stored in the body of the hive to the exclusion of brood, or the colony swarmed. That the separators were an obstruction was plainly evident. The largest yield was only 40 pounds, which amount was about 15 pounds above the average production of the 200 colonies in town. The average weight of the sections was 7 ounces.

On seven hives, the small sections were used without separators. Three were old colonies and four were swarms. Two of the former were good colonies, but no stronger than a dozen others. The other one was a nucleus last fall, and the sections were not put on until late. Neither of the three swarmed. One gave 72 pounds and 5 ounces, one 51 pounds and 2 ounces, and the nucleus nearly 25 pounds. The new swarms yielded from 10 to 15 pounds each. Foundation was only used for starters, averaging about one inch wide. The average weight of the sections was 8 ounces, and they were pronounced the handsomest sections that were ever sold in our market, commanding a ready sale at 25 cents per pound.

Four colonies were worked upon two pound sections, which were all nearly filled with clean white comb made last year. Each colony was worked to the best possible advantage on the old plan. Three were worked with section racks and one with section cases, side and top storing. The best colony gave 53 pounds and 10 ounces, one 44 pound and 6 ounces, one 36 pounds and 10 ounces, and the other swarmed.

Five colonies were worked on the old plan on one-pound sections ($1\frac{1}{4} \times 4\frac{1}{2} \times 2$). These, like the two-pound sections, were nearly filled with comb made last year. Four swarmed, and the other gave 46 pounds.

The largest other yield of comb honey was in an apiary near by, of 85 colonies on Simplicity frames. These had been strongly stimulated in the spring, while mine were fed only about 2 pounds of honey each. The best colony gave 60 pounds in two-

pound sections, each being filled with Given foundation. But this colony contained one of Mr. Doolittle's fine queens, and my own apiary is mostly stocked with this strain of bees.

The average yield of the five best colonies in town, worked on the old plan, was only 48 pounds. The average yield of the two best, worked on the new plan, in the small sections, was 62 pounds, or about one-third more, while the advantages of nearly all new comb and full sections of foundation were against them.

I am aware that the tests were not on a grand scale, but were carefully conducted; and when it is said that one-third more comb honey can be produced on the new plan than by any of the old methods, I might be "mistaken" as our friend Heddon would say; yet the advantages, in a common sense view, are clearly on the side of continuous passage ways and continuous combs.

It was thought before-hand that the small sections without separators would be fastened all together with bulged and crooked combs, and when separated, would make a "mess." But there was not one comb out of several hundred that was fastened to the adjoining section, and not one but could be readily crated. The greater number were as fine and regular as if separators had been used. They were also plump and well-filled out, while many, where the separators were used, were only partly filled. On each hive, the bees went into the sections early and began work. There was no delay. The next day after the sections were put on, the bees were found clustered in them. The difference between separators and no separators was very marked. It was found that any of the sections could be readily taken from the racks and replaced. They were also very free from propolis, so that they could be rapidly handled and put into a crate for the market at once. I could take off 36 sections (the number used on each rack), shake off the bees and have them all in a crate within 10 minutes. Where the separators were used, it took not less than a half hour to get the sections off from one rack and nearly the same time to clean off the propolis.

My experience is, that separators are not only expensive and tedious to handle, but they are always a positive hindrance to the bees, in the large sections as well as the small ones, and that not nearly so much surplus can be obtained with them as without.

Mr. Bledsoe is certainly right when he says: "The bees are quicker to go to work in common frames with good starters of foundation; more bees can get to work, and the clusters being more continuous, they make more rapid progress." (See page 382 of the BEE JOURNAL). Now, this is the principle that I have brought into successful operation by the use of thin sections, continuous passage ways and no separators. On the hive that gave the largest surplus, the racks of sections were tiered up four high, and the result, practically, was

nine combs, 27 inches high, by an average of 13 inches wide.

The queen did not trouble, in any of the hives, by going into the sections. There is, in fact, *no reason whatever* why bee-keepers should not abandon the use of the shallow chamber, so commonly provided above the brood frames. Without it, there is a certainty that bees will work to better advantage. Indeed, it seems plain enough that bees will yield more surplus where they can go straight up and down in continuous passage ways, than where they are obliged to turn at a right angle, on every trip into the sections, because of the shallow chamber, to say nothing about the 60 cubic inches of space that must be filled with bees to no purpose.

With the new surplus arrangement, no bits of wax are built any where to bother the bee-keeper, and very little propolis comparatively is used in the hive; probably because there are no places that need to be waxed up. After removing the surplus fixtures, which can be quickly done at any time without killing a bee or making the colony angry, the brood frames can then be lifted out at once. Thus, a hive having three or four racks of sections upon it, can be taken apart and put together again in a few minutes, with the least possible disturbance to the bees; and, in tiering up, the colony works right along as if nothing had happened.

Many of my double-walled hives have been made over, so as to accommodate the improved section rack; and it can be, doubtless, applied to most kinds of hives now in use by making a few changes.

New Philadelphia, O.

Utah Convention.

The Territorial Bee-Keepers' Association convened at the City Hall, on the 6th inst., at 7 o'clock p. m. President A. M. Musser called the meeting to order.

Mr. T. W. Lee, secretary of the Branch Bee Association of Tooele city, reported 26 bee-keepers, 107 colonies of bees in the spring; increased to 225, and had taken 1,017 pounds of honey. At wholesale prices (15 cts.) this amounted to \$1,052.55. Grantsville, same county, was, by order of last spring's convention, organized into a branch association by Mr. T. W. Lee, and reports 97 colonies of bees, and 2,672 pounds of honey, with 15 bee-keepers.

Mr. George Hilliard, bee inspector of Cache county, reports that in 1883 about one-half of their bees perished with the hard winter. Natural swarming had increased them to 160, and they are in a good, healthy condition. About 25 colonies had fled to the mountains, by reason of natural swarming. They have experienced one of their best seasons for honey this year.

Bishop Hills, of South Jordan, reports that he began this spring with 25 colonies, and increased to 43; had taken 5,500 pounds of extracted honey, sold for 15c. per lb., amounted to \$825.

E. Stevenson has 50 colonies in good condition; has built a bee house and sheds with a view of an increase of 100 colonies, and 8,000 or 10,000 pounds of honey next year.

Parowan, Iron county, was organized recently by the last named gentleman, into a branch bee association, with Wm. Marsden as President, Wm. Holyoake, first Vice-President, Thos. Yardley, second Vice-President, and Bishop Stone and D. Dalley as Secretaries.

Vice-President Yardley began bee-keeping 3 years ago, with 3 colonies of bees, and now has 48, and has sold 24 colonies; last year he took 3,370 lbs. of honey, and 4,000 lbs. this year.

I send the above report of the Territorial Bee-Keepers' Convention, from the Salt Lake *Herald*.

Our bees have done nothing but stay in the hives; the past three weeks has been so stormy that the bees have been compelled to stay at home. You will see from the report that Tooele has done a little, but they could have done more, I might say double, for the cause, but the principal bee men are engaged in other pursuits, and are generally engaged just in the time that they should devote to the bees. I know it has been so with myself. We have now to prepare our bees for the winter. I hope that they will come out as good as they did this spring, and if honey will do it, I have plenty of it in the hives, although it has suffered during the past few weeks.

JOHN DUNN.

Tooele City, Utah, Oct. 17, 1883.

For the American Bee Journal.

Bees Prepared for Winter.

L. J. DIEHL.

I now have my bees all prepared for the winter, 185 colonies, all in good condition. The season has been a prosperous one with me. I now have nearly two tons of fine honey on hand, in 1 and 2 lb. boxes. My bees are all healthy and strong. I have, as usual, prepared my bees to winter on the summer stands. The way I prepared them is given in previous numbers of the *BEE JOURNAL*, but I will say this, that so much fuss and flurry about preparing bees for out-door wintering is, to my mind, all bosh. The essential points are these: Have just enough bees; and 25 or 30 lbs. of good honey; and keep them dry and quieted during the winter months. This is where the trouble commences. There are so many theories and different plans to accomplish the one important matter. Keep the bees dry. In my practice with bees, this is one of the easiest duties. I prepare my bees early in the season, say just after the honey harvest closes; by uniting small colonies, taking out honey from those that have too much, and giving to those that have not enough; put on quilts, etc., early in the season, and then the bees will properly cluster, before the damp weather sets in, in the fall. Since I have adopted this plan of protection and my method of packing, I have little or no loss in

wintering. I look for considerable damp, rainy weather this winter, and I would caution all who wish to winter the bees successfully, to prepare the roofing so as to prevent dampness from excessive rain and snow, and if properly blanketed or packed inside the brood chamber, there will be but little loss of bees during this winter. I will report my success in the spring. I am not afraid, as to the results, for I have wintered at least 7 or 8 years in this way, with but small loss.

Butler, Ind., Oct. 25, 1883.

For the American Bee Journal.

A Little of my Experience

W. R. YOUNG.

I keep bees for pleasure and profit, and I discover that enthusiasm in apiculture is getting the better of me, consequently, I never expect, in this life, to be without beautiful bees, and the indispensable weekly edition of the *AMERICAN BEE JOURNAL*.

I purchased 3 colonies of natives in 1876; Italianized in 1879, by queens obtained of D. A. Pike, Smithsburg, Md., to whom we are indebted as the originator of the beautiful albino bee.

I wintered 18 colonies of Italians and albinos, and increased them, during the past season, to 30; I have about 680 pounds of surplus, in two-pound sections, and have a ready home market at 15 cents per pound. My standard of excellence for bees, is docility, industry, prolificness and beauty (golden bands).

When I hear a queen-breeder say, "I do not care for bands, but breed business bees," I decide immediately that I want none of that stock; they are hybrids, and the beautiful Italians are deteriorating in such hands. The absurd and inconsistent idea that the Italian bee, in all its purity, will not gather as much honey under the same circumstances as dark-colored bees (hybrids), is all bosh.

A good deal is said about the adulteration of honey, which is right and proper, but we should not lose sight of the fact, that the Italian bee has been adulterated with ugliness, ill-nature and crossness. With all the importations of different races, and the frequent crossings of the same with the pure Italian, nothing better has been produced. I am not quietly grinding my own axe, for I am not breeding queens for sale.

On the first of last June, one of my best Italian colonies swarmed; in due time a fine-looking young queen was hatched and laying. As the colony took kindly to the boxes, I did not disturb them until 21 days; when I examined, to see how she had mated, I was surprised to find no brood, but plenty of eggs, and my queen apparently all right. I examined weekly, and found the same condition of things. On Aug. 21, I destroyed her, as she was worthless. In all the bee literature at my command, I have not read of a like circumstance.

I build, for my own use, a side and top storing hive, and believe them to be the best for comb honey. I prefer

a two-pound section box, and use a section rack with a strip of glass set in the side, consequently I need not disturb the bees to find out when the sections are ready to come off. I have tried both tin and wood for separators, and hereafter will use only tin. With wood, the bees build too many braces to the separator, and when it is removed, the capping is too frequently mutilated, and the sections made unsalable.

Myersville, Md., Oct. 22, 1883.

For the American Bee Journal.

Wintering Bees—Preparations.

ALLEN FRINGLE.

One of the readers of the BEE JOURNAL sends me the following questions for answer:

1. The cellar in which I must winter my bees is damp. How would you prepare them for their winter quarters?

2. Should the bees be confined on what combs will contain stores enough for winter, or should they occupy the whole hive, as in summer?

In preparing bees for winter quarters, whether for the cellar or other place, the preparations should begin early in September, or very soon after the honey fails. Those with insufficient stores for winter, should be fed either honey or good syrup from No. 1 granulated sugar—about one pound of pure soft water to two pounds of sugar, brought to a boil. This should be fed during warm weather, when the bees may be able to properly cap it over. The entrances ought now to be so diminished in size that only one bee can pass at a time, especially in colonies which are not surely strong.

Among the majority of our leading bee-keepers, the practice, I believe, prevails of uniting all weak colonies for winter. On this point I differ from them. I hardly ever unite for wintering. I simply crowd the weaker colonies up into small quarters in their hives, give them plenty of stores, keep them warm, and they generally come through just as well as the stronger colonies. Of course I admit it would be foolish to attempt to winter weak colonies outside, without thorough protection; but I cannot see the wisdom or economy of taking two weak colonies, each with a good queen, destroying one of the queens if you have no use for her, and uniting them to get them safely through the winter when you can get both safely through, queens and all, without uniting them, that is, if you have a proper place to put them in. From the small nucleus occupying but one or two frames up to the strong colony covering a dozen frames, all will winter about equally well under proper conditions. Other things being equal, it is better to have two good prolific queens in the spring than one. Of course, when such colonies are put out in the spring, the proper conditions of space in hive, temperature, etc., must be supplied; and I would by no means advise the inexperienced bee-keeper to engage in wintering

weak colonies. But the skillful apiarist who understands his business can safely carry the weak colonies through, and I think such an one makes a mistake in uniting, unless he is short of queens, or wishes to weed out inferior ones, or has an unsuitable place to winter in.

After supplying all colonies with ample stores, or rather before doing so, if practicable, I go through the whole of them and diminish their quarters. I take out all light frames, and by the use of the division-board, crowd every colony up into close quarters, at the same time adding to the stores of the weak from such of the stronger ones as can spare. I cut a small hole about the size of a dime through the centre, or a little above the centre, of each frame to give the bees a free winter passage. This precaution is not so necessary when the bees are wintered in a uniform temperature of say 45° F.; but when they are wintered outside, or in a comparatively low temperature, it is absolutely indispensable, or the colony may starve with plenty of stores in the hive, the bees benumbed with the cold, not being able to get at the honey. If the division-board fits closely to the sides of the hive, with only a narrow passage at the bottom, a small hole should be put through the centre of it, so that, should the bottom passage become stopped, or nearly so, with dead bees, etc., the bees that manage to get through at the bottom may be able to get back.

Having thus given every colony sufficient stores for winter, crowded them up into the proper space in each hive, bored the division-board, removed the frames with superfluous pollen (for it is this, no doubt, which has much to do with the dysentery), and cut a passage way through the combs, the bees should be disturbed as little as possible during the last few weeks before they are put into winter quarters. Feeding them a little every evening to coax them into late breeding, will hardly constitute a "disturbance." At any rate they seem to relish that kind of disturbance. As to the proper time for putting them into the cellar, that must be governed by the weather and other circumstances.

And now, having prepared the bees for the cellar, doubtless the cellar itself needs a good deal of preparation. Mr. M., who sends the inquiries, says the cellar is damp. Most cellars unventilated are damp, except in hot, dry weather. If he means that his cellar is *wet*, he ought at once to set about draining it, if practicable. Then let him partition off the portion of the cellar the bees are to occupy, which should be the warmest portion, or that directly under the kitchen stove. Get a tinsmith to make a pipe some 5 or 6 inches in diameter, or the same size as the pipe of the kitchen stove. Let this pipe pass up from the bee department of the cellar, through the kitchen floor, immediately behind the stove, where it will be out of the way, and enter the stove pipe by means of a "T," just above the stove. There should be a damper in the cellar pipe

just near where it enters the stove pipe, so that the draft may be turned on and off at pleasure. I have had this device in use some 10 or 12 years, and it is the very best method to secure thorough upward ventilation. I have ever seen. For the ingress of fresh air from without, the subterranean passage is undoubtedly the best, especially if the air is carried a sufficient distance to have it warmed during its passage through the underground pipe, which, of course, ought to be below the frost. Provision must, however, be made for the introduction of fresh air into the cellar in some way, whether by the under-ground pipe or otherwise.

In placing the colonies in their quarters, the lower tin ought to be at least 1½ or 2 feet from the ground or cellar floor, and the summer entrances should be left wide open. All top fixtures should be taken off until the frames are exposed. Then place a thin piece of cotton, large enough to completely cover the top of the hive, and hang over the edges over the frames, with some device under it and on top of the frames, to keep it up an inch or so, in order that the bees may pass freely under it. If the cellar is to be kept at a temperature of about 45° to 50°, this will be sufficient protection on top, for colonies of average strength. If the temperature is only 40° or under, each colony must have in addition to the covering mentioned, a sawdust quilt 3 or 4 inches thick. These quilts may be made of any thin porous material, and filled in with *dry pine* sawdust, or wool, if you can afford it. No matter what the temperature of the cellar may be, it is well to have these quilts on hand for weak colonies, which require more artificial heat, also for changes of weather, which may affect the temperature of the cellar, and for spring use outside. Shelby, Ont.

Bees for Boys.—A farmer friend has 60 colonies of bees, a fine flock of light Brahma fowls, and a farm of 120 acres. He has two sons, aged 13 and 16 years respectively, and the elder boy has entire charge of the bees, of which he is very fond. He runs his sections, extracts the honey, introduces queens, divides his bees, and rears queens with a skill which many a veteran might envy. He is already well known in the city, three and a half miles distant, for his honey, and talks about bees, and quotes authorities in the most intelligent manner. All his honey is sold in one grocery store, and though he has had a good yield this season, and has reaped a fine profit, he cannot fully supply the demand at the store.—*American Agriculturist* for November.

Articles for publication must be written on a separate piece of paper from items of business.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

MR. EDITOR.—Will you allow me to say to my friends that I can no longer keep up my private correspondence, and shall be forced to leave unanswered all communications except private letters relating to business, and questions regarding bee-culture to be answered through the question department or "What and How." These questions must be sent to the Editor, and NOT to ME. This announcement is a necessity; I am sorry it is such. JAMES HEDDON.

Honey for Winter use.

Will you please answer this in the BEE JOURNAL: Will it be well to put full frames of honey in the centre of hives before putting them away for winter? H. J. NORTHROP.

Lausburg, N. Y., Oct. 18, 1883.

ANSWER.—I have known of excellent success by so doing; put in combs as free from bee-bread as possible; give them a little more space between combs than used during summer.

Preventing Granulation.

Please answer in the Weekly BEE JOURNAL: What amount of tartaric acid is required to keep sugar syrup from granulating (also honey) and whether the acid has a tendency to cause dysentery? also, is the Pelham foundation as good as the natural base? SYLVESTER MARSHALL.

Pratts, Fork, O., Oct. 17, 1883.

ANSWER.—There is some difference in sugars, regarding their tendency to crystalize. I have never had any brand or grade that would crystalize if a lump of tartaric acid the size of a small hickory nut (say round and $\frac{5}{8}$ diameter) was used for every 10 pounds of sugar. The amount of water used (that is, the thinness the syrup is to be when done) also makes a difference. That amount of acid is adapted to 5 pounds of water with 10 pounds of granulated or confectioners' A sugar. The granulated sugar, has the greater tendency to crystalize, but is preferred here. Confectioners tell us that boiling tends to boil the grain out of the sugar. Syrup that shows a strong tendency to grain before passed through the bodies of the bees, shows no such tendency afterwards, which is caused by the addition of formic acid secreted and given to the syrup by the body of the bee, while she

holds it in her sack. Regarding the acid causing dysentery, I know that it does not, and some of our most experienced apiarists have thought that it was a preventive. How that may be, I know not. Regarding the Pelham foundation, our experiments the past season (which will be reported soon) showed that the Pelham foundation is in no way objectionable on account of the shape of the base. It is a good foundation.

SELECTIONS FROM OUR LETTER BOX

Clouds and Sunshine.

I have gotten over my despondency of last April, when it seemed that my pets would all go under, but enough survived to give honey to revive my drooping spirits. I continued to read the BEE JOURNAL, and its timely hints has brought me through this season's work, and I am largely the gainer. I think, in the preparation for the next year's work. From 36 colonies, some quite weak, and several made no profit at all, I now have 85, an increase of 49; purchased 15 in box hives, and transferred them, making 100 colonies. I made 9 colonies, in partnership, in another apiary, so now I have 109 colonies in tolerably good condition. I expect to double some up, so as to have from 90 to 100, to put into winter quarters. I have taken a little over 2,000 pounds of honey, 1,400 pounds of extracted, and 600 and over of comb. I sold all the comb, and about 1,100 pounds of extracted at 12½ cents per pound, unless they took 100 pounds, then at 11 cents. I have a growing trade in honey. I shall purchase some white clover comb honey, to keep up my trade. I can retail to families in Louisville, readily.

G. W. ASHBY.

Valley Station, Ky., Oct. 19, 1883.

My Report for Six Years.

This is my bee-keeping and honey report for 6 years. I have taken the BEE JOURNAL 4 years, and shall, as long as I keep bees. My bees are pure Italians, and my hives are the Simplicity with brood frames, to hold 8 sections. I winter on summer stands, packed in fours, in sawdust:

Col. in Spring.	Fall.	Sold.	Died.	Comb.	Extrac.
1878	1	3			
1879	2	9			
1880	9	31	1	900	100
1881	30	54		1,800	700
1882	54	80	12	4,500	1,000
1883	68	100		4,000	1,400

L. D. ORMSBY.

Pierpont, Ohio, Oct. 24, 1883.

Well Done.

My bees did well this season. I obtained 75,000 pounds from 60 colonies, spring count. J. H. KENNEDY.

Little York, N. Y., Oct. 24, 1883.

Postage to Canada.

G. M. Doolittle, in the last column on page 511 of the BEE JOURNAL, says: "Samples of merchandise are mailed at 10 cents postage for every 8 ounces or less." I would like to know his authority. He says the Postal Guide says so. If it does, I cannot find it. On page 712, Official Postal Guide for 1883 (Sec. 511), it says: "Mailable matter of fourth class embraces 'samples of merchandise,' and postage thereon is one cent for each ounce," etc. If he has any later information I would like to know it.

J. L. ANDERSON, P. M.

Lawrence, Ill., Oct. 23, 1883.

[Our correspondent is informed that Mr. Doolittle was speaking of the postage on queens to Canada.]

The citation on page 712, is referring to samples of merchandise sent to any part of the United States—not to Canada! If he will turn to page 823 of the Postal Guide, volume for 1883, he will, under the heading of "Canada," in the department treating of *Foreign Mails*, see the following: "The weight of each package is limited to eight ounces, and the postage charge is 10 cents per package, prepayment compulsory."

This is unmistakably plain, and we note it here, so that there may be no excuse for any one attempting to send merchandise to Canada, of greater weight than eight ounces, except books, and the postage on each package is 10 cents; no matter if it weighs only one-half an ounce.—ED.]

Section Rack.

Would Mr. Turner be good enough to give a fuller description of the section rack used by him, than is given in his article on page 514 of the BEE JOURNAL. I do not see how glassing the last section of a row will enable one to judge as to the completion of the remainder, as the comb foundation in it would obstruct the view of the interior sections. I presume we shall hear from Mr. Heddon as to Mr. Turner's strictness in reference to the construction of the rack used by him. I am an anxious inquirer as to the best rack for adoption.

J. C. THOM.

Streetsville, Ont., Oct. 13, 1883.

Honey Harvest.

This summer has not been a good one for bees, in this section of Iowa. Last year I received 450 pounds from 9 colonies, and increased to 14 colonies; and this year to 27 colonies, strict count. I got the enormous amount of 300 pounds. I extracted 250 pounds, and took off 50 pounds in one and two-pound sections. I like the BEE JOURNAL; could not get along without it. Its instructions are very valuable to me. I hope for a better summer for bees next year.

S. J. MCKENNEY.

Burlington, Iowa, Oct. 16, 1883.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper, shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter, on your label, notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a statement of account every week.

Trial Trip, until Dec. 31.—25 cents.

Wishing to be able to reach several thousands of the old-fashioned bee-men, and by the aid of the BEE JOURNAL to lift them up to higher ground, adopting newer methods and progressive ideas, we make the following very liberal offer: We will send the Weekly BEE JOURNAL till Dec. 31, *on trial, for 25 cents.* In order to pay for getting up Clubs, we will give a copy of Fisher's Grain Tables, or Scribner's Lumber and Log Book, to any one who will send us five trial subscriptions (with \$1.25); for a club of ten we will give a cloth copy of Bees and Honey; for a club of 15, a cloth copy of the 7th edition of Cook's Manual of the Apiary; for a club of 25, we will present both the Manual and Bees and Honey. If any one wants these Books for nothing, here is an excellent opportunity to get them for a little exertion.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for ten cents.

✍ When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

✍ To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey at Fairs, will sell almost a fabulous quantity of it.

Our Premiums for Clubs.

Any one sending us a club of two subscribers for 1 year, for the Weekly, with \$4, will be entitled to a copy of Bees and Honey, in cloth, postpaid.

For three subscribers, with \$6, we will send Cook's Manual, in paper, Emerson's Binder for the Weekly, or Apiary Register for 50 colonies.

For four subscribers, with \$8, we will send Cook's Manual in cloth, or Apiary Register for 100 colonies.

For five subscribers, with \$10, we will send the Apiary Register for 200 colonies, Quinby's New Bee-Keeping, Root's A B C of Bee Culture, or an extra copy of the Weekly BEE JOURNAL for one year.

To get any of the above premiums for the Monthly BEE JOURNAL send double the number of subscribers, and the same amount of money.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

Books at Fairs.—Those who make an exhibit at Fairs will find that an assortment of Books and Pamphlets would sell and leave them a profit for handling. We will send such, postage prepaid, at 25 per cent. discount; or if the purchaser pays express charges, we will supply any of our own publications at 40 per cent. discount.

✍ The new two cent rate of postage for letters went into effect on October 1. Three cent postage stamps will now be but little used. For all fractions of a dollar sent to us hereafter we should prefer either *one-cent*, or else five or ten-cent postage stamps, or a Postal Note. Do not send coins in any letter.

✍ We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Convention Notices.

Please announce that the Iowa Central Association, will meet at Winterset, Iowa, Nov. 2, 1883.

Z. G. COOLEY, *Sec. pro tem.*

The fall meeting of the New Jersey and Eastern Bee-Keepers' Association will be held in the city of New York, at the Cooper Union, on Wednesday, Nov. 7, 1883.

J. HASBROUCK, *Sec.*

Bound Brook, N. J.

The Lorain County Bee-Keepers' Association will meet at Oberlin, Ohio, on the last Tuesday in October, 30th.

O. J. TERRELL, *Sec.*

The next regular meeting of the Mahoning Valley Bee-Keepers' Association will be held at Newton Falls, O., on the first Saturday of November, 1883.

L. CARSON, *Pres.*

E. W. TURNER, *Sec.*

The Northwestern Bee-Keepers' Society will meet in La Crosse, Wis., Friday, Nov. 16, in the City Hall.

E. MARKLE, *Pres.*

The Michigan Convention.

DEAR MR. EDITOR:—May I ask you to call special attention to our next annual meeting to be held in Flint, Dec. 6 and 7, of the Michigan Bee-Keepers' Association. We expect to have by far the best meeting ever held in the State. It is expected that the Rev. L. L. Langstroth will be present. To see and hear him will pay any one for the trouble and expense incident to the journey. We also expect D. A. Jones, A. I. Root, C. F. Muth, and hope to have C. C. Miller and T. G. Newman. From what I hear, Michigan bee-keepers are to be out in force. Hotel rates are to be \$1.00 a day. Further particulars as to programme, will be given soon. We expect to get reduced rates on the railroads. To aid in this, and that I may know how many certificates on railroads to ask for, will every one in this or other States who expect to come, drop me a card at once to that effect?

A. J. COOK, *President.*

Lansing, Mich., Oct. 15, 1883.

May we ask you, dear reader, to speak a good word for the BEE JOURNAL to neighbors who keep bees, and send on at least one new subscription with your own? Our premium, "Bees and Honey," in cloth, for one new subscriber to the Weekly, or two for the Monthly, besides your own subscription to either edition, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

Book Notices.

COPP'S U. S. SALARY LIST AND CIVIL SERVICE RULES. Our many readers will welcome the solid information contained in the 160 pages of this recently-issued book. It is prepared by Henry N. Copp, a lawyer of Washington, D. C. All the Government salaries are given from President Arthur's \$50,000 to Post-masters with \$500, officials of the Treasury, Interior, War and Navy Departments, Custom Houses, Post-offices, and fully 20,000 Federal offices arranged by States and Territories. Specimen examination questions for admittance to the Civil Service throughout the country are added. The price of the book is only 35 cents. Politicians alone have heretofore held this knowledge. The people now have a chance to learn into whose pockets their money goes, and how the Nation's income is expended.

The enterprising publishers of DR. FOOTE'S HEALTH MONTHLY have this fall, by the liberality of their premium offers, out-done all their previous generosity. The list to select from includes useful articles, standard books, and scientific literature, such as one usually expects to pay well for, but here they are thrown in with a year's subscription to the most popular and widely greeted HEALTH MONTHLY at only 50 cents a year. Try it before you buy it by sending for a free sample copy and illustrated premium list, to the Murray Hill Publishing Co., 129 E. 28th St., N. Y. City.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Do not let your numbers of the BEE JOURNAL for 1883 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

Advertisements.

A NEW HIVE

Arranged for continuous passage ways and continuous combs, so that greater ease and rapidity in the handling of sections is gained, also a larger production of comb honey. Although patented, a legal right to make and use will be accorded to any one purchasing a simple hive, the right only to manufacture to sell or convey to others being withheld. A stand, alighting board, entrance blocks, two division boards, ten brood frames, 32 1 lb. sections and the improved section fixtures, all packed in the hive. Price of first hive, including the above parts and a special circular on the mode of management, \$7.00. A fine photo sent for 8 two-cent stamps. Orders filled in turn.

Reference: Exchange Bank, New Philadelphia.

Address, DR. G. L. TINKER,
441st NEW PHILADELPHIA, O.

One Dollar per Copy.

The first and second editions of the HANDY BOOK, comprised 2,000 copies. We have a few books left which we will mail to any address, if called for soon, for \$1.00 per copy. The Book contains 216 pages—is printed in clear, large type on best paper, and is neatly bound in cloth. We have not put the book in the hands of dealers, as we chose to sell it to our customers with other goods, which we sell at prices very near the cost of manufacture them. To those who paid \$1.25 for the book, we will, on receipt of 30c. instamp, mail one of Locke's Perfection Bee-Feeders, Handy Book and Feeder, by mail, \$1.50. Send the money at any risk. Do not pay 10c. to register it. Prospectus and special circulars describing three new and useful articles for the apiculturist, sent to any address. Make Postal Notes and Money Orders payable on Salem, Mass., P. O.

HENRY ALLEY,
WENHAM, MASS.

CHICAGO, ILL., NOVEMBER 7, 1883.

No. 45.

ESTABLISHED IN 1864
THE AMERICAN
BEE JOURNAL
PUBLISHED EVERY WEDNESDAY, BY

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Ripen the Honey.

We have just had a jar of honey brought to us to see if it was pure. The owner being fully satisfied that it had been "doctored" with glucose. We examined it and found that it had fermented, and the top of it was all a "ropy mass." A case of *sour* honey.

Another correspondent has sent us a sample, and asks us to analyze it, because he thinks it is adulterated. We are not a chemist, and cannot afford to hire these specimens analyzed "just for the fun of the thing." It would cost from \$10 to \$25 to do so, every time.

One of our exchanges very truthfully remarks that "the nectar gathered from the flowers cannot be called honey until the evaporation and ripening process has so far gone on that the bees have commenced capping it over. If it be extracted before it is capped by the bees, as some apiarists recommend, on account of the quantity being thereby greatly augmented, then it should be ripened before it is placed in tight packages or shipped, or it is liable to ferment and sour. The beekeepers of California find it necessary to extract the honey as fast as it is gathered, but they thoroughly ripen it after gathering."

Mr. Heddon uses crocks, piled over one another, with small sticks between them, allowing the air to pass freely over the honey, and to ripen it. These occupy but little space, and prevents the very disagreeable matter of honey souring, after it has been extracted.

It is the duty of the producer to see that his honey is ripened properly. No excuse is sufficient for neglecting this important matter.

The Effect of Frost on Foul Brood.

Prof. A. J. Cook says in the *New York Tribune*, that "experience has proved that it is impossible to destroy germs of foul brood by freezing. Observation among the lower life forms, as well as research with organic tissues and liquids, prepares us for the answer. Many of the lower organisms, which are speedily destroyed by great heat, will simply remain functionally inactive when subjected to cold. Yet their vitality is simply held in abeyance, not destroyed, for upon the return of heat comes functional activity and all the phenomena which attend life. The same thing is noted in experiments with organic liquids. Gastric or pancreatic digestion will proceed as well in a test tube as in the stomach of intestines, if the requisite conditions of heat, digestive liquids, etc., are present. Subject the material to a boiling temperature, and digestion is not only stopped, but the digestive liquid is forever impotent. Cold, on the other hand, while it stops digestion does not impair the gastric or pancreatic juice. With the return of the proper heat, digestion at once begins again. Thus we see that protoplasm or organic cells will endure cold which only stays action, while heat utterly destroys."

☞ We have received the drawings of Dr. G. L. Tinker's new hive and comb honey arrangement. As it is designed for the sections to sit parallel with the brood frames, he secures continuous passage ways, and to the bees what appears to be continuous combs. This is, of course, secured by using *thin* sections without separators. These large-faced *thin* sections have been approved by honey dealers, and are more enticing to consumers.

☞ See how the subject of "producing pasturage for bees" progresses! From an agricultural exchange we clip the following advice: "If honey is the principal desideratum in planting, then harrow in sweet clover this fall, and as you will derive but little if any honey from it next season, in early spring harrow in some mammoth mignonette on the same soil, which will bloom in June, and astonish you with the excellence of its honey."

Nonsensical Stories.—Sensational stories about bees and honey are quite frequently seen in the papers. Somewhere in the rocks (says one) may be found "a large lake filled with honey!" In the South "they say" that bees will store no honey because they have discovered that there is no need of winter stores where Nature requires no winter! A lot of such foolish stories are being peddled around by the local papers. This reminds us of an item we saw some time ago in the *Farmers' Review*, of which the following is a paragraph:

When anything sensational gets into the papers, how it does go! I presume that many readers of the *Farmers' Review* read the story about artificial eggs, but I doubt if any of them saw any of the eggs. Closely following the eggs story, was the highly flavored one of artificial comb honey—combs molded from paraffine, filled with scented glucose and the combs sealed over with a hot iron! We shall have artificial *strawberries* yet! Where, and how, such absurd stories originate, it is often impossible to say. About a year ago, an item in regard to managing bees by electricity, went the rounds, and now it goes around again.

☞ When in earnest is quite surprising what a man can do. Dr. B. F. Hamilton, a well-known physician and surgeon of Henderson County, Illinois, has sent us 27 new subscribers. If all those who have a little leisure would do as much in proportion to the busy Doctor, what a "boom" we should have! The Doctor has received as *premiums* quite a number of excellent bee books. Those who want to add to their libraries, will now be able to do it, for a few hours work in getting subscribers for the BEE JOURNAL. Who will try?

LATER.—Mr. D. G. Parker, one of the wide-awake bee men of Missouri, has sent us 39 new subscribers. They are rolling in at about a hundred a day. All those who are thus devoting a little time to the matter, have our thanks as well as the premiums. See a new List of Premiums on another page.

More Experiments.

The *Canadian Farmer* says more experiments are called for in connection with the pursuit of bee-keeping, and then remarks on the subject thus:

After all the numerous important improvements realized in bee culture, still the more advanced investigators seem disposed to proceed, under the impression of not having yet fully apprehended all the conditions and elements of attainable success. While the many experimental failures seem to almost suggest doubt as to the desirableness or prudence of proceeding in this direction, yet it may be asked, how else can we reasonably hope to attain to the knowledge essential toward placing our beloved bee-keeping as to result above a peradventure?

In fact, sometimes from even a grievous failure much may be gained in discovery of what may have been the mistake causing the disaster. We would be loth to admit that most of the worst cases of failure and "blasted hopes" might not have turned out under other conditions very differently.

Surely there are for instance certain laws and conditions of safety in wintering which, if only well enough known and possible to fulfil, we might with ample confidence count on the number to be brought through all right. Now facing winter, must we look wintering in the face.

However, it does look rather humiliating to admit that with all the skill and experience here employed hitherto, yet so many of us are earnestly asking one another (and feeling need to ask), "how are you deciding to winter?" Now this is just what we are driving at. We do well to more fully and freely than ever inform each other, and every time give the why and the wherefore. Whatever may be the seeming confusion and conflict of theories, still we are even so on the hopeful way in the search for the better. Thus as we cautiously proceed, keenly watch results, and candidly admit errors, may we all become wiser and more successful.

Dr. Miller will feel flattered by the announcement in an agricultural paper that at the Chicago Convention he led off the discussion on "foul breeds," claiming that the most effectual remedy as well as the "most heroic, being total destruction." Oh! doctor, "how could you so cruel be?" This mixture of "foul breeds" and heroism is truly refreshing!! but it shows about the amount of intelligence possessed by the average agricultural writers when they "dabble in bee lore."

The Northwestern Bee-Keepers' Society will meet in La Crosse, Wis., Friday, Nov. 16, in the City Hall.
E. MARKLE, Pres.

Oleomargarine Must Go.

The *National Farmer and Stockman* has this to say about that fraud oleomargarine:

The Georgia Legislature has taken the initiative in forcing oleomargarine out of the market. That body has passed a bill which requires all manufacturers of the vile stuff to plainly label their product; all dealers to notify customers when it is offered them; and all hotels, restaurants and other places of public entertainment, where it is used, to put the notice on their bills of fare and post the sign in their dining-rooms. "This house uses oleomargarine." We sincerely trust that all of the legislatures in the States of the Union will adopt such a measure as Georgia has, and if our readers in the various States will visit their members of the legislature and insist on them offering such a bill and their supporting it with their best efforts, it then will be brought into prominent notice, which will stir the legislatures to speedily pass it or some other law equally as effective in abolishing it from all markets in America.

Just so; the frauds must go! But let the acts of legislature also include that greater fraud—glucose. Let it strike a death-blow on all the adulterations of the age, and their name is legion. It is high time that the adulterators were driven to the wall.

The Michigan Convention.

DEAR MR. EDITOR:—May I ask you to call special attention to our next annual meeting to be held in Flint, Dec. 5 and 6, of the Michigan Bee-Keepers' Association. We expect to have by far the best meeting ever held in the State. It is expected that the Rev. L. L. Langstroth will be present. To see and hear him will pay any one for the trouble and expense incident to the journey. We also expect D. A. Jones, A. I. Root, C. F. Muth, and hope to have C. C. Miller and T. G. Newman. From what I hear, Michigan bee-keepers are to be out in force. Hotel rates are to be \$1.00 a day. Further particulars as to programme, will be given soon. We expect to get reduced rates on the railroads. To aid in this, and that I may know how many certificates on railroads to ask for, will every one in this or other States who expect to come, drop me a card at once to that effect?

A. J. Cook, President.

Lansing, Mich., Oct. 15, 1883.

P. S.—I got the date of the above Convention wrong, in the notice of last week. The date should be Dec. 5 and 6.

A. J. Cook.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Honey and Beeswax Market.

OFFICE of AMERICAN BEE JOURNAL,
Monday, 10 a. m., Nov. 5, 1883.

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The demand for honey is extremely slow, and our commission houses are too well supplied to expect anything else. Prices rule low. Manufacturers complain of slow business. Extracted honey brings 7@8c, on arrival. I have bought for less. Comb honey in good order, 12@15. BEESWAX—Good yellow beeswax brings 27@28 cts.; offerings few.

CHAS. F. MUTH.

NEW YORK.

HONEY—White clover and basswood in 1 and 2 lb. sections, 17@21c. Dark and second quality, 14@16c.; extracted white clover in kegs and barrels, 9@10c.; dark, 8c. BEESWAX—Prime yellow, 27@29c.

H. K. & F. B. THURBER & CO.

CHICAGO.

HONEY—The demand for honey is good. Choice 1 lb. sections of white comb, well filled, brings 18@20c.; 1½ lb. to 2 lb. sections, 16@18c. No demand for dark comb honey. Extracted honey is bringing 8@10c. per pound, according to body, color and flavor.

BEESWAX—Prime yellow, 33c.; medium, 28@30. R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Market is well stocked with ordinary qualities. Inquiry for the same is not active. For fancy comb it is an easy matter to secure custom. White to extra white comb, 16@18c.; dark to good, 12@14c.; extracted, choice to extra white, 7½@8½; dark and candied, 6½@7c.

BEESWAX—Wholesale, 27@28c. STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Choice in better demand, but unchanged. Sales chiefly in a small way. We quote strained and extracted at 6½@7c. Comb at 14@16c.; choice, in fancy packages, higher.

BEESWAX—Readily salable at 26@27 for choice. W. T. ANDERSON & Co., 104 N. 3d Street.

CLEVELAND.

HONEY—Choice honey is in excellent demand now. Every lot received thus far in good order, has been sold on arrival; best 1 lb. sections bringing 18c. quickly, occasionally 19c.; 2 lb., 17c. with an occasional sale at 18. Second quality and broken lots are very hard to sell. Extracted honey not in demand.

BEESWAX—28c. A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—We quote extracted honey at 10@11c., with a good demand. We have sold easily four times as much extracted as we ever did before.

BEESWAX—We have none to quote.

BLAKE & RIPLEY, 57 Chatham Street.

KANSAS CITY, MO.

HONEY—No change to note since last week's report. All shipments seem to be taken up as fast as received at 16@18c. for comb, and 7@8c. for extracted in 5 gallon square tin cans.

JEROME TWICHELL, 536 Delaware Street.

It would be a great convenience to us, if those sending us Postal Notes or Money Orders, would get the issuing Post-master to make them payable at the "Madison Street Station, Chicago, Ill.," instead of simply "Chicago." If they are drawn on Chicago, they go to the general office, and we have to make a trip of six miles to get them cashed; when if they are drawn on the Station as above, it is only a few steps from our office. When sending us money, if you will please remember this, you will much oblige the publisher.

CORRESPONDENCE

For the American Bee Journal.

Humidity, Cold, Confinement and Pollen—their Relation to Wintering.

S. CORNELL.

In replying to some of Mr. Heddon's observations on the above matters, I shall be as brief as possible.

On page 464 of the present volume of the BEE JOURNAL, Mr. Heddon states that bees have often been taken out of special repositories perfectly drenched with dampness, and the combs covered with blue mold, but with the bees perfectly healthy. I doubt the correctness of the latter part of the statement. I think Mr. S. F. Newman is right when he says, "If the hive becomes damp and the combs moldy the colony cannot be healthy." Mr. Heddon frequently refers to an occasion when Mr. Balch's bees were taken out as described above. The probability is that they were removed just in time to save them by giving them an opportunity to dry out, in dry air. Mr. Balch is represented as believing that moisture is good for bees and that ventilation is death. In the winter of 1880-1, owing to steady cold and consequent confinement they had no chance to get dried out all winter, and, in consequence, he had lost 149 out of 150. Mr. Heddon states that Mr. Balch's damp cellar, where the bees did not die, was colder than his own dry one where 45 out of 48 did die. Had he given us the accurate temperature and humidity of both cellars, the facts would have been of some value. As it is, he proves nothing.

He states that the dampest winters were the warmest ones. The records of the Signal Service show that the winters of 1874-5 and 1880-1 were both the coldest and dampest of any during the last decade. They were also the most disastrous to bee-keepers, in wintering. He says that "cold" and "confinement" as causes of dysentery have both fallen to the ground, and that when he has shaken up the "humidity" theory a little more, it will tumble with them. Will it, indeed? We shall see. "Humidity," "cold" and "confinement" as factors in wintering bees are based on facts in physical science, ascertained and established long before Mr. Heddon or myself appeared on the scene, and will remain unshaken long after we have passed away and are forgotten.

On page 391 of the BEE JOURNAL for 1882, Mr. Heddon correctly shows how the water produced by the assimilation of food taken in winter is eliminated by the bees, except that he attributes it all to transpiration, when in reality the greater part of it escapes by exhalation. This is the first fact, and I remark in passing, that just there Mr. Heddon was at the very verge of discovering the root of the whole matter. One step more and he

had it. The step which he did not take is my second fact, viz: that in a saturated atmosphere of the same temperature as the bee, there can be no evaporation, consequently no excretion of moisture, either by transpiration or exhalation. This is where humidity comes in as a factor. A little bit of theory deduced from this fact and from what is known regarding other animals, is that since the bees cannot eliminate the water produced by the consumption of food, they will be in an abnormal condition, and we have Mr. Heddon as authority for saying that it is when bees are "out of normal condition" that they eat pollen to excess, (if they ever do so).

The third fact is, if the temperature of the colony be say 88, and the humidity 80, out of a possible 100, a sudden drop in the temperature of 7 degrees will cause saturation of the air and condensation of vapor in the hive, and the air will remain saturated at the new temperature as long as the conditions continue unaltered. This is where cold comes in as a factor.

Dr. Wetherill, of the Smithsonian Institution at Washington, says: "The rapidity of the evaporation of the body depends principally upon the low relative humidity of the air at a high temperature and upon the maintenance of this condition in the neighborhood of the body by the action of currents of air. In an atmosphere saturated with moisture the evaporation would be reduced to a minimum and would be practically nothing in such air having the same temperature as the body. Although we may bear with impunity these extremes for a short period, a persistence in such conditions would be fraught with danger." In the same way bees may bear such conditions for a short time without apparent injury, but when they come to be confined for several months without a chance to get dried out, it is not surprising that they have to succumb. This is where confinement comes in as a factor.

When ventilation is imperfect there is undoubtedly another factor in the case, namely, carbonic acid gas, but owing to the difficulty in detecting it, ordinary observers cannot know much about its proportion in the air. A superabundance of it acts in about the same way, in preventing the escape of carbonic acid, as aqueous vapor does the escape of water from the body of the bee. Here is what Kuss, a German author, says on the matter: "If an animal be shut up in a confined space, and a sufficient quantity of oxygen be admitted while the carbonic acid produced by respiration is allowed to accumulate, the animal will die as soon as the proportion of this gas becomes too great. Not that carbonic acid is poisonous, only that the excess of this gas, or its too great pressure in the air, hinders the egress of that which is in the blood; the blood is then prevented from collecting the gas evolved from the combustion of the tissues, and the respiration of the latter becomes impeded." Want of oxygen also probably plays a part, but if we bear in mind that "the essential point

of good ventilation is constant change of air," and make our arrangements accordingly, we need have no fears as to the supply of oxygen. The degree of humidity is taken by the most careful writers on ventilation to be a correct measure of the purity of the air of an apartment. This can readily be determined by the careful use of a hygrometer, which anyone of ordinary intelligence can soon learn to use with sufficient accuracy.

POLLEN. — One might reasonably expect that after discussing this question for nearly three years, its advocates would surely have shown beyond doubt that bees sick with dysentery have consumed excessive quantities of pollen. There is plenty of assertion but nothing approaching a proof of the fact. But suppose bees do at times eat unusually large quantities of pollen, the next enquiry is, why do they sometimes eat too much and at other times none or only enough for good health? Mr. Heddon's answer is that they eat it either because they do not like their liquid stores, or, on account of the pollen floating in the honey, consuming it is unavoidable; or else they are confined by cold till the honey within reach is consumed and they must eat it or starve. This theory will not cover the facts of ordinary observation, as I shall presently show. Then, too, it should be shown that excessive eating of pollen causes dysentery. If it were agreed on all hands that the "dry feces" theory is a mistake, and that bees discharge their feces only in a liquid state, it might be considered as giving a certain distance in that direction. But I think, notwithstanding Prof. Cook's investigation of the matter, there is a pretty general belief, amongst bee-keepers, that bees do void their feces in a dry state, when in perfect health, while in winter quarters.

In the following case, pollen as the primary cause of the loss is entirely out of the question, and yet it is only one out of hundreds of similar cases occurring all over the country every winter.

In the fall of 1879 I purchased 10 colonies, in box hives, from a Mr. Webster, residing some seven miles out of town. I brought them home in the latter part of October, and after sitting in my garden a few days, during which they flew, they were stored in my cellar with about twenty other colonies of my own. Mr. Webster had in all 42 colonies, and my 10 were about equal to the remaining 32. He advised me when placing them in the cellar to raise the hives an inch or so above the bottom board and to pull out one of the plugs of rags which stopped the holes in the top, stating that he had always done so and succeeded well. I had read a very interesting and instructive essay on "Insect Respiration and Bee Culture," in which everything seemed so plain and reasonable that when the writer said, before winding up, "our bees will need scarcely any air, and hence no ventilation, either upper or lower," I adopted that as my creed on ventilation of hives and held to it for several years. Another writer, too, advised

that the heat of the bees be confined, consequently I set my box hives on the bottom boards in the cellar as they stood in the yard, without any ventilation, except a small three-cornered notch, for a flyhole, in the edge of the hive. Mr. Webster's cellar was an ordinary one for household purposes, but roomy and frost-proof. Mine should have been the better of the two because I had an exhaust pipe and a short sub-earth pipe for fresh air.

Now for the result: In the spring, 8 of my 10 colonies in box hives were dead, and the remaining 2 died before the 1st of June. The bees were a wet moldy mass; the combs daubed with discharges and dripping with wet, and the honey, of which there was plenty, thin and soured. My other 20 colonies in the same cellar covered with a quilt, and in hives having 2 sides of straw, wintered well, as my bees had done in the same cellar for several years before. Mr. Webster's 32 colonies came out every one in good condition. Now what was the cause of the difference in the results? It could hardly be in the honey, for even if colonies in the same yard do sometimes gather from different sources, it is extremely improbable that I should happen to get only those having bad honey, and that Mr. Webster should get all the others. For the same reason it will not be contended that I got all those having pollen in the middle of the hive or floating pollen in the honey. They were not selected on this basis, for the pollen theory had not then being "guessed," and the bees had as good access to their stores in the one case as in the other. The true explanation is that my bees were killed by their own breath, while Mr. Webster's, having similar conditions in every respect, except as to ventilation, kept dry and came out in good order.

In the "Bee-Keepers' Instructor" for April, 1882, Mr. Heddon says: "When I see a colony of bees that have nothing to eat but pure sweet cane syrup, of proper consistency, have the dysentery, I will of necessity change my mind, and honestly say so, publicly, at once." A few days ago I asked him to put a colony on combs of best cane sugar syrup without a grain of pollen and place it in a hive covered outside with pitch, bottom, sides and top, the joints to be made air-tight, the fly-hole to be reduced to half an inch by one quarter or three-eighths, and sealed after the bees had clustered; the hive to be placed in a cellar so that the bees could not get into dry air till next spring. If he follows those directions I think he will have a case of dysentery without pollen. I also asked him to supply several colonies with combs discarded from others on account of having too much pollen, but containing also plenty of honey. These hives were to have the entrance open full size and the back end of the frame exposed, leaving an opening across them as large as the entrance, the same as is done with such good success by Mr. Geo. Grimm. But for fear the old bees should die and stop the circulation, I asked him to bore

two auger holes, one at each end of the frames, two-thirds of the way up. The hives were to be placed in a cellar having a steady temperature of from 44° to 50° and a relative humidity of from 55 to 75; and about the latter two conditions there was to be no guesswork, but accurate determination by proper instruments. If I were running an insurance company I would insure bees put up in that way to live for a premium of 5 per cent. and have a margin for profit.

Section-Storing Cases.

JAMES HEDDON.

Ere some of the less experienced be led, what seems to me, astray, I will comment upon Mr. Turner's article on page 514 of the current volume.

Since I have kept bees, I have made and tested as many as a dozen different devices for holding sections on the hives and to their sides, and generally made these tests upon quite an extensive scale.

I am well aware that no one system of surplusage embraces all the good points, but of all the most impractical and objectionable ones, two mentioned by Mr. Turner are the worst, viz.: "glassed" and "movable side" cases. Movable sides render a case not only more expensive, but impracticable and less durable. A movable-sided case was on exhibition at our late rousing Northwestern Convention. Of course there were no divisions in the case, such would not be adapted to the movable side. The dependence was upon clamping the sections, to prevent their falling through, and as long as there is any variation in the shrink and swell of wood, this method of supporting sections will ever be dangerous and impracticable, and used only by inexperienced bee-keepers. Such a case is weak, and incapable of enduring some of the most important manipulations.

"Glass" is one of the most objectionable materials that can be placed next to bees. They sorely neglect those combs that are next to glass. It may be true that the novice may learn more by looking through a glass at the outside of the outside comb of a range of 6 or 8 than he can by looking between the ranges of all the combs (both at their tops and bottoms) of a properly-constructed case, but the experienced producer will discover the condition of all the sections in a case in less than half the time consumed in peeking through glass at their sides, and with four times as great accuracy.

I can remove any one section up out of my case as quickly as any movable-sided case gentleman can do the same job. Admitting that any one of my sections require more time for removal than does his, after his side is removed, yet the fact that this removing and re-adjusting of said side requires time, it leaves the speed of the removal of any one section in favor of the solid case.

Now, as regards the total emptying of all the sections in a case, the "knock down" process will discount the movable-side plan. I can empty a case in less time than Mr. Turner can open and re-adjust the side of his case, I think. We can more than doubly discount the time required to take the same number from broad frames, and all who have ever seen the case manipulated here, agree that no system admits of the rapid and easy removal that we enjoy with the case.

Mr. Turner's statement that the sections should rest flat on the slats of the honey board, and flat on each other, is certainly laughable, and brought out a hearty laugh from three or four of our large honey producers who read it in the JOURNAL office at the time of the Northwestern Convention.

Certainly, Mr. Turner never had a large apiary to attend to. The idea of the practical and ready manipulation of tiers of sections, that set flat down upon each other, is something that I cannot conceive that any practical producer can entertain. Now, as regards any advantage of any such a bee-smashing arrangement, there is none whatever. Bees will not put as much glue upon the face of a section that is $\frac{3}{8}$ from any other surface, as they will squirt in between two pieces that do not fit each other perfectly tight, which is the case with all sections that lie together.

Regarding these spaces interfering with the work in the surplus receptacles, we find they do nothing of the kind; nearly every year we have had a portion of our bees without honey boards, thus leaving off the thickness of the board and one bee space, and no one can detect any difference in our surplus success, between the two methods.

Mr. Turner's mention of shoving one section past another, thus "running the risk of breaking the capping," proves that he does not understand our system; that he does not know that we use $\frac{3}{8}$ spaces between the tops and bottoms of our sections; that with our foundation and method of using the same, we get our combs nearly as straight as with separators; that when we push out our sections, we push them six at a time, which makes the entire row, leaving no chance for breaking the cappings, were the combs ever so crookedly built. I am willing to leave the matter now to the coming practice of honey producers; the same offer I made regarding the Dean case, two years ago.

Central Illinois Convention.

The Central Illinois Bee-Keepers' Association met at Bloomington, Ill., Oct. 10. President Wolcott in the Chair.

On motion of Mr. Vandervort, a report from each member is requested to be made, and returned by Dec. 10; blank reports to be sent by Secretary to members.

The first subject called for discussion, was "Wintering."

The President said that the most important matter is in the preparation of bees, in the fall, for winter. They should be let alone, and not disturbed. Sometimes he shoveled snow around the hives.

Mr. Vandervort wintered his bees on the summer stands with straw in the caps, holes in the honey boards, and the hives let down close to the bottom boards. He had one experience in wintering bees in the cellar. The hives and combs came out, in the spring, wet and moldy, and the bees in bad condition. He did not want any more cellar wintering.

Mr. Cox used cloth over two strips, placed across the frames, with chaff packing at the sides, and was successful.

Mr. Butler put about one-half of his bees in the cellar, and left the rest on the summer stands two years ago; and in the spring those from the cellar were moldy, and in very unsatisfactory condition. Those outside were in much better condition. Last winter he packed 27 colonies in chaff, on the summer stands, and they all came through nicely.

Geo. Poindexter was decidedly in favor of cellar wintering; he thought the two essential points to success were: "Put the bees in a frost-proof repository, and give plenty of upward ventilation to allow the dampness to escape from the bees." Last winter he lost 3 colonies out of 200, so wintered.

Mr. Cox found the moisture escaped much better with 4 inches of chaff, than twice that depth over the bees.

President Wolcott used 1½ inches of sifted coal ashes over the bees with satisfactory results.

It was asked which was preferable—passages over the frames or holes through the combs? The opinions differed according to each one's experience.

"On Marketing Honey," Jas. Poindexter thought that honey put up in two-pound packages could be produced at less figures, and suit regular honey consumers as well as smaller packages. Sections of two-pounds each, holding 1,000 pounds of honey, cost but little more than half as much as one-pound size to hold the same amount; less sizes required much more handling, both for the producer and retailer. That the cost of production in small and fancy packages would have the tendency to keep honey regarded as a luxury, while in larger and cheaper packages, it would tend to make it a staple article, and bring it into more general use.

Mr. Cox had trouble in disposing of honey in larger packages than one-pound.

Jas. Poindexter thought that depended on the way grocery-men were educated by bee-keepers.

Mr. Fell asked if honey in combs, placed on the top of the cloth, would be removed by the bees for winter use? Answered: If the weather is warm, they would.

"Do bees mark their location from the color, or the surroundings?" Mr.

Jordan transferred bees from an unpainted box to a white hive. In shaking the bees in front of the new hive on the old stand, they were loth to enter, until a piece of the old hive was placed in front and against the new hive, when they entered readily, which he thought indicated they were attracted more by color than the hives on either side of the new one.

Jas. Poindexter said that a part of the hives that he had taken from the cellar in the spring were closed; after the other hives were placed out, and the entrance open, in a few minutes the bees, in considerable numbers, were noticed hovering around the closed hives, 25 feet away, which occupied the same relative position to the trees as the one fresh put out; some of these hives were of different colors. There were closed hives of the same color on either side, much nearer to the hive newly set out. He thought that bees marked the surroundings more than the color.

Mr. Funk noticed that swarms sometimes entered the wrong hive when returning, entering a hive similarly located to the one from which they issued; he was of the opinion that the relative position of the hive was marked more than the color; all his hives are painted white.

"Which is preferable for honey, black, hybrid or Italian bees?" Answered by Messrs. Funk and Keeran in favor of hybrids.

Adjourned to the second Wednesday in January, 1884, when the regular annual meeting of the association in Bloomington will be held.

JAS. POINDEXTER, Sec.

Wintering—the Pollen Theory.

DR. G. L. TINKER.

Since Mr. Heddon has given us to understand that he has no "confidence" either in his twin theories or his little prophecy, there is little for me to say in reply to his last article. It is to be remembered, however, that Mr. H. is a man of undoubted liberal views—one who is ever ready to abandon anything that will not comport with the evident facts of nature; so we find him saying, almost mechanically, in "What and How:" "While it may prove true that pollen-eating may be the cause of dysentery, in every case it may turn out a fact that under most favorable conditions bees *can* consume bee-bread during confinement and yet remain healthy." The uprooting of cherished views finds expression only in a lingering doubt on the last proposition. This is encouraging. The pollen theory must go!

Mr. Heddon intimates that I believe the "bacteria theory" will account for some of the cases of dysentery. No; I have simply suggested it as a more plausible one than the pollen theory, and so applied it to the loss of the 48 colonies alluded to. A very reasonable hypothesis in the few isolated cases that now and then occur is to be found in the use of aphide

honey. However, no one has been able to give positive evidence that any kind of nectar or sweet that the bees naturally collect, such as cider, the juices of various fruits, &c., may cause dysentery. Of the unnatural agents, it is well known that chemical glucose will kill bees if wintered upon it, probably by a poisonous action.

Thus, we have gone over the probable and improbable causes of bee-dysentery, and the preponderance of evidence rests with the humidity theory; or in other words, that dampness in the hive, conjoined with a low temperature, is the probable cause. This is no new statement of the theory, as Mr. H. would infer. It was assumed from the first that dampness and cold were co-operative causes; not by inducing an inflammatory state of the intestines, or even perhaps an irritation, but by causing an interference with the exhalations of the bees through the act of respiration, resulting in an accumulation of liquid in the intestines that under more favorable conditions would have escaped by the breath in the form of aqueous vapor.

The remaining question between Mr. Heddon and myself is in regard to the proper size of the brood and surplus department of the hive in winter. His experience that 8 Langstroth frames are safer to winter upon than 10, is no doubt correct. But I consider that to leave even 8 frames in the hive would be unsafe in a very hard winter. Better by far to reduce the number to 4 or 5. My choice of the standard L. hive in preference to a very narrow one was with this view; since, by placing a division board each side of the 4 or 5 frames, there is room left to put at least 3 inches of loose chaff on each side, and in the cap to place a large cushion. But with Mr. Heddon's hive there is not room for sufficient packing *close up* to the bees. This want of space Mr. H. would make up by a cumbersome outside case holding 6,000 cubic inches. Beyond question if a colony in an 8 frame hive were put in such a case it would be far less safe than in the standard L. hive, prepared as above, with no outside case at all.

I believe that with a long, shallow frame there is no real necessity for double casing of the hive at the ends of the frames; hence, my statement that so much "fixing" would not pay. No reference was made, or even thought of, to Mr. Heddon's hive in the production of comb honey. That would have been too great a diversion to appear under the heading of these articles.

As for out-of-door wintering in an 8 frame hive, doubtless Mr. Grimm would have no better success than Mr. Heddon has had. The latter, therefore, gets credit for making the best possible use of a hive unsuited to successful wintering on the summer stand. In an article on page 7 of the BEE JOURNAL, present volume, I stated that Mr. Heddon's method of wintering was "very doubtful" as compared with the others given, and, in a letter to Mr. Doolittle about the same time, predicted that he would meet with

heavy loss if the winter continued at all severe. Yet our friend had just assured us that he could now winter bees as safely and surely as horses, cows and other farm stock could be wintered.

Swarming vs. Dividing for Comb Honey.

ISAAC HUTCHINS.

If we allow bees to swarm they will cast their first swarm at or about the commencement of the honey season, and in about twelve days we may expect the second swarm and in four days more the third—I think this is the average time of swarming; therefore it is sixteen days from the time the old queen leaves the hive with the first swarm until the third swarm issues. Then the young queen will commence to lay in about ten days more, making twenty-six days that no eggs have been deposited in the old hive and twenty-six days that no bees will hatch. Each of the three swarms have taken a large portion of the old field bees so that the old colony will be deficient in worker bees during all the time from the going forth of the first swarm until they raise them from the young queen, which will be at least fifty-five days. Fifty-five days being the extreme length of our honey season, excepting the fruit and fall flowers, the old colony will do well if it stores honey enough to carry it through the winter.

The first swarm commences house-keeping under more favorable conditions, nearly all of the worker bees are old enough to go into the field to gather honey, and they have a laying queen which will occupy the brood chamber, and they will readily go into the surplus boxes to store their honey; but as it will be nearly thirty-five days before the young worker bees will hatch and be old enough to take their places in the field, nearly one-half of the worker force will die before the young will take their place, so this colony will not do as well as it would if it had a few sheets of brood in all stages when they first commenced, so as to keep their numbers good all through the best part of the honey flow.

The second swarm issues about twelve days later, and the young queen will not commence laying until the second week. They will hatch no worker bees before the basswood honey harvest is over, and nearly two-thirds of the worker bees will die before the young bees come forth to take their place; and as more than one week will pass before the queen will occupy the brood combs, the bees will commence to store honey in them and they will not readily go into the boxes afterwards, and our experience is—usually no surplus honey from second swarms.

The third swarm will be very much smaller than the others, and unless we have an extra honey season it will have to be fed if we winter it. There-

fore, if we allow our bees to swarm as they please, we shall get surplus honey from only the first swarm, and not so much from that as we should if we kept them strong in numbers all through the honey season.

How shall we prevent our bees from swarming and keep all our colonies strong to store surplus honey?

I answer by dividing in such a manner as to have each new colony as strong as possible and keep them from swarming, giving each a portion of the brood and a laying queen, being sure to give them room enough, and each division will be as good as the first swarm. Then they will have the advantage of having bees continually hatching, so there will be no dwindling during the honey harvest and we may expect better results from each division than from the first swarm, thereby giving us double the amount of surplus honey with only one-half of the increase.

Wellington, Me.

For the American Bee Journal.

Northwestern Bee-Keepers' Society.

A. R. KOHNKE.

The knowledge conveyed in the report of the meeting of this society is well worth a year's subscription to the BEE JOURNAL to any bee-keeper.

Speaking of races and strains of bees, there seems to be a preference for crosses, especially to overcome the aversion of the Italians to go into sections. I think there is a difference in this trait of character between colonies of pure Italians. Since such differences exist, may not this aversion be bred out and still preserve purity of race?

The prolificness of queen and the industry of colony do not necessarily go together. I have an Italian colony the queen of which is very prolific, having kept the hive and 48 sections full of bees ever since June 10th. The proceeds from that colony at the end of the season were 9 pounds of comb honey, and of extracted, about as much from unfinished sections; and on examination before putting them up for winter, I did not find more than 9 pounds of honey in the brood chamber. The bees look like what Mr. Heddon calls the "Golden Italians." The Germans have done better for me, (for comb honey).

The fact that bees try to supersede not only old queens but very prolific ones also, has led some bee-keepers in Germany to suppose that extraordinary prolificness may be a reason for bees to supersede the queen.

Bee-keepers should try to profit by Mr. Burnett's experience in regard to the size of sections. Sections in which the sealed comb is or cannot be much thicker than sealed comb in the brood chamber, would perhaps be more readily taken to by the Italians, while those two inches wide may seem to them out of all proportion in comparison to their lower apartment.

"Jane, take this honey down cellar," said a lady to her servant girl, after I had sold her a crate of nice

clover honey. Of course, I stopped them right there, giving some sound advice as to where to keep that honey.

DYSENTERY.—If Mr. Heddon had omitted one word in his reply to the Rev. L. L. Langstroth when he says: "but they are sometimes compelled to eat it." (pollen,) he would have given the sole and only reason for bees dying with it. Drop the word "sometimes" and you have the whole thing in a nutshell. Whenever a large amount of pollen is covered with honey or sugar syrup, bees clustering on that will get the dysentery, if they cannot readily leave that, when they get to the pollen, "which is at the bottom," as Mr. Oatman expresses himself; but I think this latter gentleman is mistaken if he thinks covering pollen with honey or sugar syrup will prevent the malady. Bees will not cluster on dry pollen because they cannot live on it, but should it be covered, they will. Result, dysentery; unless mild weather permits them to move.

As to the new bee enemy, described by Prof. Cook, I would suggest treating the affected colony to a good dose of tobacco smoke—not enough to stupefy, and after ten minutes or so, transfer them to a clean hive and scald the one they were in. It may be necessary to repeat the treatment after a week or ten days.

Youngstown, Ohio, Oct. 30, 1883.

For the American Bee Journal.

Equalization of Colonies of Bees.

J. E. POND, JR.

I presume that every intelligent bee-keeper that gives his own time to the care of his apiary, has noticed that of a dozen colonies, all apparently in like good condition, 1 or 2 will give exceedingly good results comparatively, while the balance will hardly come up to mediocrity in the amount of surplus obtained from them; and I myself have noticed one thing further, (which I presume is not exceptional,) that, of a dozen colonies, the 1 or 2 that gave the best results last year, would be this year among the majority from which a poor yield is gained. This has been my experience for years. At first I concluded it must be owing to superior strains in the superior colonies, and endeavored to remedy it by making such changes as would—theoretically, at least—equalize the matter, but when, the next season, I found the best colony of the previous year showing a decidedly poor state of affairs, I concluded that something besides poor stock was the cause of the trouble. My aim in my own apiary is, not to raise 1 or 2 colonies which would store an exceptional amount of surplus, but to put my whole apiary into a condition such that each colony would give a fair amount of gain, and the average would be nearly equal in each colony also. This I have found it impossible as yet to do; no matter how careful I am in choosing queens, or how much attention I pay to equalizing the condition of my stock, the result in the

fall inevitably is that 1 or 2 have far exceeded the others in the amount of honey gathered. I have studied the matter to some considerable extent, but have not as yet fully solved the problem of why this is so; still I have formed an opinion in regard to the matter and will venture to give it, hoping that it may not be looked upon as the chimera of a visionary, or the vagary of a disordered intellect, but instead will create enough interest in the matter to start an amicable discussion in regard to it.

My idea is that each colony chooses a foraging ground, which may vary from year to year, and consequently the amount of stores gathered will vary also, depending upon the amount of honey-producing flowers growing thereon. It is supposed that a radius of three miles from an apiary comprises the ground usually covered by its bees. I conclude that while all this territory may be, and probably is, covered by a large apiary, the individual colonies that compose such apiary have their own favorite localities, which may change somewhat, but which will be visited so long as any amount (no matter how small) of honey is found; and that this locality is not abandoned so long as any honey can be gathered therefrom.

If my reasoning is not correct, it certainly is possibly so, and until someone gives better, I shall stick to my opinion. The remedy, if any there is, and I admit that a remedy is almost impracticable, is to plant honey-producing flowers in every direction from an apiary, as a means of aiding nature to counteract her own sterility. With a small apiary it will make little difference, but with a large one it will, I think, make enough to be fairly appreciable. At any rate some good will result from efforts made in this direction, the difficulty being to perform the labor in a manner such as will bring about the best results. Who will give the subject some attention, and the readers of the BEE JOURNAL their views upon it?

SHALL WE HYBRIDIZE OUR BEES?

Mr. Heddon claims to have made such progress in crossing his bees as to have obtained a new strain, with characteristics so fixed that they are invariably reproduced, and that from the strain so obtained, to gain the best results. Hybrids have always been considered valuable as honey gatherers, their exceeding ferociousness being the principle objection brought against them. I myself have made some attempts in this direction, but I admit I have most signally failed, and that too where my own bees are the only ones within probable flight-range of any apiary; some five miles being the nearest distance at which any bees are kept. I have crossed the black drone with an Italian queen and "*vice versa*," but have never been able to fix any qualities save crossness. Stripes of all kinds, from 3 to none, and of all shades of color have been found, but nothing have I been able to produce in the matter of equalizing either color or number of bands. I am a lover of beauty in everything, but do

not carry it in my apiary to the extent of sacrificing other qualities to the maintenance of beauty alone.

I have had Italians for 17 years, and more, and have found them far superior to the blacks, and as a rule, far superior to any hybrids. I have occasionally found a hybrid queen whose workers were the best of workers, but have not been able to fix those qualities so desirable to retain, but have been able to do so to my satisfaction with the Italians. I do not say it is impossible so to do, but it does seem difficult to create a new strain (using the term strain for all it implies,) from hybrids (the Italians are now admitted, I believe to be hybrids, using the term hybrid to mean a cross,) when it has taken so many years to make *them* what they are.

I have no doubt Mr. Heddon has produced excellent bees, but will they stand the test, as do the Italians, of being kept alone for a term of years? That question as yet remains to be answered, and my advice to beginners (the old ones can take care of themselves,) is to go slow in the matter of running after new things. The Italians have been fully tested, and stand the test too; their record is made, and it is a good one; so I say be careful in selection; take nothing upon credit in making a start, and as you become older in the business and gain in experience, you will be better able to judge of the value of making experiments in new fields and with untried instruments. I do not wish to be understood as detracting from the value of Mr. Heddon's new strain, far from it; he is a bee-keeper of experience and honesty, but I do wish to deter any beginner from leaving the old beaten track until he fully knows the new paths and can safely follow them. Foxboro, Mass., Oct. 26, 1883.

Read at the Maine Convention.

Mortality of Bees—Winter & Spring.

WM. MCLAUGHLIN, M. D.

Adversity and losses often teach us more important lessons and produce greater range of thought than prosperity and gain. So the usual mortality of bees during the winter and spring may be an incentive for us to make further investigations, learn more important facts, and yet discover some means to avert or prevent this fearful drawback on bee-keeping in our State. And when we consider what enormous losses have been sustained, year after year, it behooves every one who has any interest in the success of apiculture to "help, aid and assist" all those means and measures designed to bring about so desired a result. It is no part of wise men to say that our present attainments are sufficient, that we know all about bee-keeping or that we should settle down on a standard frame for all sections and climates, but rather by experimentation and practical research try to discover other and better methods of carrying our bees through our severe and long winters and springs.

I took considerable pains last spring

to canvass at least one town, the town of Harmony, in order to accurately estimate the death rate of bees and the causes that led thereto. And I believe when we know the particular cause we may apply the treatment or preventive measures, and thus attain our desired results. There were 16 bee-keepers in this town the past year and the whole number of colonies put into winter quarters was 80. Three colonies were in the Torrey hives, 10 were in box hives and the rest were in the Gallup hives or some modification of it. A very few were wintered in cellars, some in house chambers, while the most of them were left on the summer stands. Those left out doors were protected by an outside hive or house with a 6 inch space filled with chaff and a chaff cushion over the frames. Now out of the 80 that bid fair to winter, only 50 came through alive, making the loss by death 37½ per cent., a fearful loss indeed! Upon careful examination I found those that died in cellars starved to death with no honey in the hive, which showed that they would have lived if there had been food enough in the hives; while 20 colonies died on the summer stands in Gallup hives and protected with chaff and outside hives, and honey in one or both ends of the hives. Twenty colonies died of starvation with a plenty of honey in the hives.

Honey to the right of them,
Honey to the left of them,
Honey by side of them,
But none above them,
Suffered and hungered,
Died there unnumbered,
Some one had blundered;
Their's not to make reply,
Their's not to reason why,
Their's but to do and die,
A score of swarms in eighty.

The treatment or preventive measures, it seems to me, are self evident. We must either winter in cellars or so construct our hives that they may winter safely on summer stands. If we could have the temperature in the hive above the freezing point all the time, and have a plenty of sealed stores, we should not lose our bees to any material extent; but so long as we cannot expect to do that, it is necessary to ward off all the cold we can. But this packing is inconvenient, and results are so uncertain that they will die unless we adopt the natural means which the bees would claim if they were able to speak. We all know that bees cluster on the approach of winter beneath their winter's store in the middle of the hive, and when the air within is too cold for them to go sideways, they naturally approach the upper part of the cluster, for the heat of their bodies and breathing keeps their combs immediately above them in a condition for their occupation. They cannot go across or sideways for it may be frosty and contrary to their nature when the air is cold and chilly.

Now if we can so construct a hive or frame that shall give depth of honey above the cluster, we shall have an additional assurance that our bees will not starve in winter or perish with cold. And further we must protect our colonies to such an extent that the temperature within the hive may not fall below the freezing point.

For the American Bee Journal.

My Experience with Foul Brood.

R. C. HOLMES.

In July, 1882, the flow of honey being good, I noticed that the bees of one of my colonies were idle and listless while the other colonies were at work. I had only to take off the cap of the hive, and lift out a frame, to find both by the odor and appearance a case of "foul brood." The concave brood caps, with perforations, the dead brood, dark-colored and rosy, and bad smell, all being present. I had read so much about it, that my heart grew sick within me, and I felt as I once did, after working half an hour in endeavoring to land a two-pound trout, and finding that it was only a "sucker."

I put the frame back and left the bees until near dusk. I then set a box beside the hive, and after smoking the bees pretty thoroughly, brushed them off the frames into the box, putting on a cover (in which was a hole about 6 inches square, covered with wire cloth), and fastened it on. I then set the box away in a dark stall in my barn, and let it stand from 36 to 40 hours. I then took a clean hive, put it on the same stand, put in it frames of foundation, and emptied the bees out of the box into it. I put on a feeder containing some granulated sugar syrup with a little salicylic acid mixed with it. The colony drew out the foundation, stored nearly enough honey to take them through the winter, and I had no more "foul brood" there.

I then proceeded to examine my other colonies, of which I had 20 in all. I found 6 other colonies infected with the disease, 4 only slightly, and 2 seriously. I determined to try some experiments, and having read your valuable JOURNAL for a year or two, and kept the numbers on file, also owning A. I. Root's "Bee-Keeping," Cook's Manual, King, Quinby and Langstroth books, I had quite a library to draw from. I took the worst case left, and placed a clean hive on the stand, in which were new frames with foundation, and brushed the bees immediately from the infected combs on to the foundation, and put on a feeder with syrup and salicylic acid as before. The colony also built out the foundation, stored enough honey for winter, and has showed no signs of the disease since.

The other 5 colonies not being as seriously affected, I determined to try and save the combs if I could. I procured a solution of salicylic acid, according to the recipe given. I think by C. F. Muth, also by A. I. Root, and a sprayer, and sprayed the combs and bees thoroughly every week, and sometimes oftener, until I thought the disease eradicated. It certainly decreased, and seemed to disappear. On looking over my bees in October, I found that it was not eradicated, and in one hive it was quite bad.

I brimstoned the bees in that hive, and buried the combs, as I also did those of the first two colonies mentioned. The other 4 colonies were in brick hives, with a cement lining in-

side, and I determined to try to save them. I sent to L. C. Root & Bro. for some empty combs, having none myself, and transferred the combs to some new frames, took the bees out of each hive, washed out the hives, every crevice and corner with salicylic acid, filled the combs as well as I could with syrup, and brushed the bees on to them. I have never seen any "foul brood" since.

As it is now a year since I saw the last of it, I feel that I eradicated the disease from my apiary with the loss of only one colony. I did not burn or destroy a hive. I washed them out thoroughly with the acid, let them dry in the sun, and have since used some of them. The query with me was, where did the disease come from, as it is said only to proceed from some other diseased colony.

I kept very quiet about it, only my wife and oldest son knowing of the trouble. I have several neighbors who keep bees, one, only a few rods distant, who has a colony in a cupboard, or large box in the attic of his shop. About the first of May last, I asked him how his bees were doing. He replied that they died out in the winter. I asked him if he had removed the combs, and he replied that he had not. I suggested to him that he had better do so soon, or the moths would destroy it all.

A week or two later I asked him again if he had removed the comb, to which he replied that he had, that a few of the outside combs were nice, and had nice honey in them, but that the inside ones were all rotten, and stunk so that it most made him sick taking them out. I then guessed I knew where my "foul brood" came from.

The yield of white clover and basswood honey here, this year, was better than for the three previous years, but of fall honey not enough to safely winter on, and I have been feeding several colonies.

West Winsted, Ct.

For the American Bee Journal.

How about that Foul Brood?

J. M. HICKS.

I see on page 531 of the excellent BEE JOURNAL a short note taken the apiary department of the *American Grange Bulletin*, of September 20; and which it seems has been the cause of Mr. C. F. Muth asking the BEE JOURNAL to reproduce it, and says, "it looks so much like a slur," &c.; and then by way of reply he offers to stake \$50 against \$10 of Mr. Hicks' money that I (Hicks) cannot cure foul brood without using what he calls his remedy, &c.; and still to make the matter more showy, Mr. Muth offers to wager \$5 against \$1 of Hicks' money that he (Hicks) cannot prove ever to have seen a colony of bees affected with malignant foul brood. Now, Mr. Editor, let me say if I were so inclined, or ever had been a gambler, I might very easily relieve the gentleman of his \$55; but having been reared under different influences,

I must decline Mr. Muth's special proposition. But if Mr. Muth has really taken umbrage at that note, and thinks that I intended it as a slur on him or any other member of the the North American Bee-Keepers' Society, I am sorry, as it was not so intended, but merely a question asked and reference made to the long and labored reports by certain members of the convention on foul brood, and after all no definite conclusion arrived at, except a banter by 2 or 3 of the members to stake \$50 as a fund for the benefit of Mr. Langstroth in case the cure was, or was not, affected in 1 or 2 different ways, as mentioned by C. F. Muth and D. A. Jones, each of whom had a pet theory of their own, of which I need not mention now.

I thought so little of either process as mentioned by the gentlemen; especially so when it was to be tested on a wager of \$50 and to be the special fund of an old and honored bee-keeper as well as a minister of the gospel. So far as I am concerned, and as being weighed in the balance with any man who desires to judge my capacity and ability of knowing what foul brood is and curing the same, I shall only say I was quite well acquainted with the disease in 1870, and lost several colonies of bees at that time, until I stopped its ravages and further spread among my bees, which has been over 13 ago; to-day I have no signs of the dreaded epidemic diseases known to bees.

Further, here let me say that I stated (when I had an opportunity so to do,) at the North American Bee-Keepers' Convention, in 1882, that an ounce of prevention was better than a pound of cure, and gave my plan of same; and that, too, without favor or reward, and have never charged a cent for giving the knowledge of same to any who so desire it. Further, let me say, so far as Mr. Muth's plan and use of salicylic is concerned, it is no new thing, and has been known for many years as a remedy, only as a failure, for foul brood. I claim no special honors for using rock salt as a preventive, which I know it to be from many years of experience, and trust it may do much in preventing such a loathsome disease as foul brood from spreading.

I am well aware that I do not know it all yet, nor do I make such pretensions, but hope to be able to guide my little pets, the bees, safely through, and reap my reward accordingly.

Battle Ground, Ind., Nov. 1, 1883.

☞ May we ask you, dear reader, to speak a good word for the BEE JOURNAL to neighbors who keep bees, and send on at least one new subscription with your own? Our premium, "Bees and Honey," in cloth, for one new subscriber to the Weekly, or two for the Monthly, besides your own subscription to either edition, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Putting Bees in the Cellar.

At about what time should bees be put into the cellar?

Monroe, Wis. N. STAININGER.

ANSWER.—At that time when you think the season is going to give them no more chance to fly. We usually wait until snow comes apparently to stay, and we do not fear to carry any amount of snow into our cellar.

SELECTIONS FROM OUR LETTER BOX

No Surplus from Fall Flowers.

Bees have done very well in this section of country, except in fall honey; the bees have not stored any surplus this fall.

JOSIAH EASTBURN.

Fallsington, Pa., Oct. 28, 1883.

How was it Done?

In the BEE JOURNAL for Oct. 31, J. H. Kennedy, Little York, N. Y., states that his crop is 75,000 lbs. from 60 colonies, spring count, but he does not state the increase. I commenced the season with that number (60); increased by aid of empty combs to 141, and took 14,559 lbs., which might, by close extracting, have been made 20,000, possibly. Now, an average of 1,250 lbs. is something that I am not quite prepared for, without knowing how it is done! Will Mr. Kennedy instruct a novice through the BEE JOURNAL?

J. C. THOM.

Streetsville, Ont., Nov. 1, 1883.

My Best and Poorest Colonies.

The following is my report for 1883 of my best and poorest colony: Best colony, No. 9, cyprian, gave of comb honey, in one-pound sections, 282 lbs.; extracted honey, 48 lbs.; in hives, 157; total, 487 lbs. Increased to 5 colonies. Poorest colony, No. 11, Italian, gave of comb honey, in one-pound sections, 80 lbs.; extracted honey, 25 lbs.; in hives, 105 lbs.; total, 210 lbs. Increased to 3 colonies.

FRITT'S COTTAGE HIVE APIARY.

Niles, Mich., Oct. 29, 1883.

My Season's Work.

My report for this season is, spring count, 8 colonies; 2 were queenless, and had to rear their own queens, by giving them eggs. I increased by artificial swarming to 27 good colonies. I reared many of my own queens; but had some sent me from Henry Alley, James Heddon and A. I. Root. I obtained 717 lbs. of honey (693 lbs. of ex-

tracted and 24 lbs. of comb honey). I have on hand 35 frames of good sealed clover honey for spring feeding, if they need it, and each colony has from 25 to 30 lbs. of good honey to go into winter quarters with. I sold 2 colonies (hybrids) for \$10. I am going to winter my bees in three different ways. I am leaving some on their summer stands, in double-walled hives, packed with paper and sawdust; some in a repository, and some in clamps. I am using the standard Langstroth frame. I used the American frame before, but I like the Langstroth the best for handling and for winter use.

WM. SEITZ.

Hustisford, Wis., Oct. 27, 1883.

How I Started to Keep Bees.

I have long contemplated writing a short note for the BEE JOURNAL, expressing in a feeble way my indebtedness to the Editor and his able correspondents, for much instruction, benefit and pleasure. It was by the merest accident I became an apiarist, and by chance a reader, yea, a student of the BEE JOURNAL. A swarm of bees settled near my place. I took them in very handsomely. In a few days an agent for a moth-patented hive came along, explained its excellence, as an agent knows so well how to do, especially to one who had not been enlightened upon the hive, by reading the BEE JOURNAL. I then thought it the hive; took the bait, \$10 worth, for a farm right. And, again, by chance, I, this spring, became the possessor of an apiary of 30 colonies—a bold step, I hear you say; true, it was. However, by studying; by simply devouring the BEE JOURNAL and the Manual, I have been equal to the emergency. When I met rocks, shoals and quicksands, I immediately turned to my file of BEE JOURNALS, and there found the needed light. I got my bees all moved by the last of January. On the first day of February they were on the wing, bringing in pollen—there, I will leave for the present.

JNO. A. EMISON.

Mission Valley, Texas, Oct. 12, 1883.

Pollen or No Pollen.

In Bruce, Ontario, the past season was, upon the whole, favorable for bees. The early part of the spring was very backward; cold and wet continued very long, so the white clover began to appear only about June 20, but it then became very abundant and healthy, and was followed by the basswood blossoms which were very plentiful.

I see that lively discussion regarding pollen or no pollen in wintering bees is still going on. The non-pollen theory seems to me to be contrary to nature. Bees, in spite of our theories gather it wherever and whenever they can, and with very great care and skill, store it up for future use. This is taught by a law which man cannot ignore. We know also that they need pollen earlier in the season than they can gather it in the fields. Bees shut up for five months will be of little value the following season if for want of pollen they are prevented from

breeding till they are placed on their summer stands.

The success of the bee-keeper in northern climes depends very much in having his hives full of young bees when placed on their summer stands; but this cannot easily be got if pollen is excluded from their winter stores. I say, then, let the bees have their pollen which they have so industriously gathered and stored under their honey. But let them have plenty of ripe honey with their pollen, or good syrup, which will do just as well; then they will not injure themselves by eating pollen, but will use it only when they need it. The want of liquid food drives them to the pollen, and too much of it will sicken and destroy them.

J. ANDERSON.

Tiverton, Ont., Oct. 27, 1883.

Kansas Bee and Honey Show.

Mr. Newman: As I have not seen anything from anyone about it, I will say that they had a very nice Bee and Honey Show at Hiawatha, Brown Co., Kansas, Fair. The officers were well pleased with the display and said they would encourage that department more another year. I. W. Margrave had a nice display of comb and extracted honey, bees, queens, hives, &c. John Witschy had some nice honey and queens; the writer had 2 colonies of bees and honey, which was most all spoiled by the express agent; also, an extra fine queen was shown by D. A. Pike, Smithburg, Maryland. The premiums were on comb and extract honey, best hive and tools for apiary, J. W. Margrave, Hiawatha, Kansas; best queen, D. A. Pike, Smithburg, Md.; best colony of bees, D. G. Parker, St. Joseph, Mo. D. G. PARKER.

St. Joseph, Mo., Oct. 30, 1883.

Questions for Mr. Doolittle.

I wish to ask Mr. Doolittle what style of frame, how placed, what size, 1 or 2 stories, would he adopt if starting anew into bee-keeping, for extracted and comb honey?

C. M. MOLESWORTH.

Building Comb Upwards.

I am an amateur bee-keeper. Two years ago I started with one colony of Italian bees and an observation hive. I have been very much interested in the working of the bees, and have watched them closely this spring. I took off my observation hive, which was full from last year, and gave them room to work. I noticed that, contrary to what I expected, they did not commence to build from the top downward, but built the comb upwards from the bottom. They seemed to pay no attention to the frames and built it diagonally across the hive. What I want to know is, if filling a hive in that manner is of frequent occurrence? Although they built comb upwards they did well. I have now 10 colonies and have all I can attend to.

EDGAR L. GROSS.

Springfield, Ill., Oct. 28, 1882.

[Bees do sometimes build their combs in this manner, but not often.—Ed.]

Alsike Clover.

I have raised alsike clover for five years in succession, and I find it to be one of the best honey plants, while it lasts, that I can raise; bees will work on it by the side of white clover. I have been to old pasture fields that were lined with white clover and would scarcely find a bee, and then go back to the alsike and found it booming with bees. Besides, it makes the best pasture and better hay than red clover. It does not get as dusty as red clover hay, and rain does not pile it as soon.

A. B. MILLER.

Wakarusa, Ind.

Sowing Mignonette Seed.

Will the BEE JOURNAL please ask Prof. Beal to answer the following questions through the BEE JOURNAL in regard to mignonette:

1. Which does Prof. Beal consider the best for bees, *reseda odorata*, *rese odorata grandiflora*, *ameliorata*, Parson's new white and new hybrid spiral?

2. Can mignonette be sown in drills in the fall?

3. How much should mignonette be sown in drills to one acre?

4. How wide apart should the rows be?

5. How wide apart should mignonette be planted in drills?

6. How often should mignonette be sown?

7. Will mignonette, after sown, remain permanently?

A SUBSCRIBER.

Indianapolis, Ind., Oct. 14, 1883.

In reply to the above queries, I give the following answers:

1. They are all very good. I should sow for the main crop the most common kind, and sow small plats of the newer kinds, and in this way ascertain which is the best.

2. No.

3. I should sow at least one seed to every inch in the drill.

4. About 9 inches.

5. Thinned to 4 inches.

6. In March (in hot-beds) and in May.

7. No.

W. J. BEAL.

Lansing, Mich., Oct. 29, 1883.

Not a Good Season.

The season for 1883 has come to a close, and I can by no means call it a good one. My 30 colonies of bees wintered without loss, although in May and June it was cold and rained most of the time. When clover was in bloom it rained some most every day, and very little honey was gathered from basswood. In September we had two hard frosts that killed all of the fall bloom, so I had to feed one-half barrel of A sugar.

When the honey season began I had 25 strong colonies and 3 weak ones; they increased to 62 strong ones, and I have taken 1,182 pounds of comb honey in prize boxes, and the most of it is sold for 18 and 20 cents per pound.

I have them all packed, sides and top, with fine oat straw, and will put them into the cellar some time next month.

CHARLIE W. BRADISH.

Glendale, N. Y., Oct. 29, 1883.

Moving Hives for Winter Packing.

I have my hives scattered all over the yard, about 6 feet apart; will it do to move them all in one row, about 6 inches apart, so that I can cover them, except the front, which I wish to face to the east? Some tell me that if I move them, the bees, when taking a flight, will return to the place their hive stood before moving, and will perish. I wish your opinion.

JOHN W. STURWOLD.

Haymond, Ind., Oct. 26, 1883.

Thickness of Sections.

I have heretofore predicted that wide frames and separators for sections would, in the near future, be discarded by our best honey-producers. If we take the Chicago Convention for an example, three-fourths of the members present producing their honey without separators, we may expect to see the time soon, when they will be discarded. I get straight combs with closed-top sections, and straighter combs with small starters than with whole sheets, Mr. James Heddon to the contrary notwithstanding. In regard to the proper thickness of sections, without separators, for combs, say from 4 to 5 inches square, I would suggest $1\frac{3}{8}$ inches; is this too thick or too thin? As we will soon have our bees packed away for winter, and will be preparing for another year's crop, can we not have some discussion on the above subject from those of experience, such as James Heddon, G. M. Doolittle, W. Z. Hutchinson, C. C. Miller and others. There are many who are undecided as to how they will secure their honey another year, and views from those of experience would certainly prove very beneficial. The experience of R. A. Burnett shows that thin combs of the same weight sell better than thick ones. Is the queen more liable to enter the boxes and deposit eggs in thin combs than thick ones? Will not the combs be built straighter when thin than when thick? Who will explain first, and benefit those to whom it may concern?

A. J. FISHER.

East Liverpool, O., Oct. 27, 1883.

Chaff Hives Wintered in the Cellar.

Mr. J. T. Matthews, in an article entitled "Cellar vs. Chaff Hives," read before the Central Michigan Convention and published in the present volume of the JOURNAL, page 299, reports having placed "3 chaff hives in the cellar" to test them on an equal footing with single-walled hives, to see the effect on "spring dwindling." As there is no further mention made of them in the article, and as there are several points besides "spring dwindling" to be taken into account in the adoption of a method of winter protection, will Mr. Matthews kindly inform the readers of the BEE JOURNAL

how many pounds those colonies in chaff hives decreased in weight while in the cellar; also their condition when removed and at the beginning of the honey season.

FRANKLIN P. STILES.

Haverhill, Mass., Oct. 26, 1883.

Make a Note of it.

Bees have done very well for the kind of season; they average about 55 pounds of honey to the colony; increase, 80 per cent. They go into winter quarters in this unusual condition; no fall honey; no fall bees; no fall pollen—all old bees, with pure clover honey. Now, please remember what the result of the wintering will be, and make a note in your calendar of philosophical beedom. I speak only for my own locality.

E MCNITT.

Harlem, Ohio, Oct. 26, 1883.

Open Letter to Mr. F. L. Dresser.

DEAR SIR.—On page 454 of the AMERICAN BEE JOURNAL, is an article under your signature, headed "How to Clean Wax." After giving us your method of using the Swiss extractor for that purpose, you state in the latter part of the article that you have a further addition to the extractor, by which you can render the wax white as originally made by the bees. Your article, as far as it went, was very good. Now, please state how this instrument is made, and how you use it, and then your article will be much better, and your bee brothers will find it doubly interesting.

L. JAMES.

Atlanta, Ill., Nov. 1, 1883.

One-third of a Crop of Honey.

So far as I have been able to learn, bee men in this vicinity have had a small yield of honey, this season. Perhaps one-third of an average crop; all, or nearly all of which will find a home market. A fair number of swarms was secured, and nearly all colonies are in good condition for the coming winter.

L. JAMES.

Atlanta, Ill., Nov. 1, 1883.

Book Notices.

There is no better companion for man than a good wife, but next comes a good book, and if it is instructive as well as entertaining, the time in reading it is well spent. Dr. Foote's "Plain Home Talk and Medical Common Sense" is held in high esteem by the judges of good literature, and all classes of readers praise its clear style, enjoy its variety and profit by its instruction. Thousands have bought it and more have borrowed it, but every family should have one of its own now that the price is only \$1.50, and it can be had by mail, prepaid, from the Murray Hill Publishing Co., 129 E. 28th St., N. Y. City.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper, shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter, on your label, notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a statement of account every week.

Our New List of Premiums.

Getting up Clubs for 1884.

To increase the number of readers of the BEE JOURNAL, we believe, will aid progressive bee-culture and help to elevate the pursuit. We, therefore, offer the following premiums for getting up clubs:

While no subscription to the BEE JOURNAL will be taken for less than the regular advertised prices (viz.: Weekly, \$2.00; Monthly, \$1.00),—any one getting up a club of two copies, or more, may select from "OUR BOOK LIST" anything therein named, to the amount of 15 cents for every dollar *they send direct to this office*, to pay them for the trouble of getting up the club; and these books will be sent, postpaid, to any address desired.

For a club of 3 Weekly or 6 Monthly and \$6.00, we will make an *additional* present of a Pocket Dictionary, bound in cloth, containing 320 pages.

For a club of 5 Weekly or 10 Monthly, (or a mixed club of both,) with \$10, we will, in addition to the 15 per cent, present a copy of the AMERICAN "POPULAR" DICTIONARY, comprising every word in the English language that enters into speech or writing; it contains 32,000 words and phrases, 670 illustrations and 512 pages; it is nicely bound in cloth, and will be sent by mail, postpaid, to any address desired.

For a club of \$20,—10 Weekly, or its equivalent, we will present, besides the 15 per cent, a tested Italian queen.

Announcements for larger clubs will be made hereafter.

Subscriptions for two or more years for one person, will count the same as each year for a different person.

☞ When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Trial Trip, until Dec. 31.—25 cents.

Wishing to be able to reach several thousands of the old-fashioned bee-men, and by the aid of the BEE JOURNAL to lift them up to higher ground, adopting newer methods and progressive ideas, we make the following very liberal offer: We will send the Weekly BEE JOURNAL till Dec. 31, *on trial, for 25 cents*. In order to pay for getting up Clubs, we will give a copy of Fisher's Grain Tables, or Scribner's Lumber and Log Book, to any one who will send us five trial subscriptions (with \$1.25); for a club of *ten* we will give a cloth copy of Bees and Honey; for a club of 15, a cloth copy of the 7th edition of Cook's Manual of the Apiary; for a club of 25, we will present both the Manual and Bees and Honey. If any one wants these Books for nothing, here is an excellent opportunity to get them for a little exertion.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for ten cents.

☞ The new two cent rate of postage for letters went into effect on October 1. Three cent postage stamps will now be but little used. For all fractions of a dollar sent to us hereafter we should prefer either *one-cent*, or else five or ten-cent postage stamps, or a Postal Note. Do not send coins in any letter.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

Sole Manufacturers,
Sprout Brook, Mont. Co., N. Y.

A NEW HIVE

Arranged for continuous passage ways and continuous combs, so that greater ease and rapidity in the handling of sections is gained, also a larger production of comb honey. Although patented, a legal right to make and use will be accorded to any one purchasing a sample hive, the right only to manufacture to sell or convey to others being withheld. A stand, alighting board, entrance blocks, two division boards, ten brood frames, 32 1 lb. sections and the improved section fixtures, all packed in the hive. Price of first hive, including the above parts and a special circular on the mode of management, \$7.00. A fine Photo sent for two cent stamps. Orders filled in turn.

VOL. XIX.

CHICAGO, ILL., NOVEMBER 14, 1883.

No. 46.

THE AMERICAN BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Mr. Gravenhorst's New Bee Book.

Mr. G. has kindly sent us a copy of his new book, entitled: "Der Praktische Imker," (The Practical Apiarist) of which we will give a short review.

On page 11, a cut represents the hive he uses. It is made of straw, after the fashion of the straw skep of the "days of yore," but its shape is such as to admit of the use of frames; all being of the same size. The base of the hive has a rectangular shape, but the upper part or cover has a cylindrical form, and is perfectly tight. This makes it necessary to have the upper part of the frames of a round form, and they are accessible only after having the hive turned "upside down."

To keep the frames in position, the upper part of the same catches in notches, in a bar fastened in the crown of the hive, while the projecting shanks, having holes, are fastened to the hive with iron pins or wire nails. The hive has two or three entrance holes, the main one being in the lower half, and the others in the upper half of the hive, being about equally distributed on one side of the hive.

As the large hives take 15 frames, of nearly the same size as a Langstroth, it enables the apiarist, by the aid of division-boards, to winter two or three small colonies in one hive. Mr. G. claims for his hive certainty of wintering without loss and rapidity of handling the bees.

The hive is especially adapted for extracting; surplus honey is obtained by side storing. Though sections may be put into the large frames, as shown on page 170, but leaving, of course, empty corners on account of the

round shape of the large frame. Unquestionably the bees will winter well in this hive, but we doubt whether the yield obtained by side-storing will be as large as by top-storing.

The engraving, intended to a Langstroth hive, is quite inaccurate, for it conveys the idea that the top-bar of the frames is an inch or more below the upper edge of the hive, when it is, in fact, only $\frac{3}{8}$ of an inch below; and as shown in the hive, the top-bars seem to be closed, which is not the case. Otherwise, the cuts and general make-up of the book are a credit to the publishers, C. A. Schwetschke & Son, Braunschweig, Germany.

One very important chapter is omitted, viz.: the one on honey plants; to provide pasturage in case of failure at certain seasons, the apiarist is advised to practice migratory bee-keeping. In fact, this is practiced to a very large extent in Germany, generally with success, especially if the distance is not very great, so as to permit occasional visits. In this case, they consider over-stocking out of the question, for upward of a thousand colonies are sometimes placed in one range.

In the chapter on stimulative feeding, in spring, besides the flour of wheat, rye, oats and peas, a diet of milk and eggs is advised. The use of the latter diet requires the hand of a master, in preparation and feeding; withal, the book shows the hand of an experienced master.

The entomological part is written in a very concise and comprehensive manner, describing and illustrating only such parts and their functions as are absolutely necessary for an apiarist to know in order to understand the economy of a colony of bees. The illustrations on page 70 and 71 are excellent, and give a better idea of the abdomen of a queen and the relative position of its parts in the body, than many pages of description.

Two remedies are given to cure foul brood; one by the aid of salicylic acid dissolved in alcohol, and the other by

the use of carbolic acid. Whether or not the author has tried this remedy, he does not say, but if we remember correctly, Prof. Butlerow's attempts to use it have not been very satisfactory; because of the disagreeable penetrating odor, the bees would leave the hive within five to ten minutes after the disinfectant had been used; and much less than one per cent. mixed with their food was sufficient to poison them; but the methods employed may make all the difference.

We shall take the liberty to occasionally give extracts of such chapters as may prove interesting to our readers, and would recommend our German-speaking apiarists to procure a copy, as the book contains many valuable hints not only to beginners, but to the experienced also.

We have received 3 numbers of a new French bee paper called *Le Conservateur des Abeilles*, edited by Mons. A. Fournier, and published at 27 rue Vandamme, Paris, at $3\frac{1}{2}$ francs (75 cents,) a year. It represents the more progressive of French apiarists.

We have received a copy of the *Dairy and Farm Journal*, published monthly at West Liberty, Iowa, and notice that the Rev. E. L. Briggs is one of the associate editors.

And now comes Mr. P. Brickey, of Kentucky, with a club of 28 new subscribers, besides quite a number of smaller clubs. Our new premiums for clubs (found on another page,) are attracting considerable attention; and as the time is now at hand for getting up clubs, we hope to send out hundreds of premiums to enrich the libraries of our friends.

We have received No. 1 of a new German bee paper—the *Deutsche Illustrierte Bienenzeitung*—edited by C. J. H. Gravenhorst, Braunschweig, Germany, and published monthly at \$1 a year. It contains 16 pages, and is the best printed bee paper in Europe.

The Honey Crop of 1883.

Last June the outlook was very encouraging to the honey-producer, but alas, for human anticipations, from the 1st of July, and in some localities from the last week in June, there has been but little honey gathered, with a very few exceptional localities. The fall crop has been exceedingly light, and many are obliged to feed the bees for winter stores. Dr. W. G. Phelps, of Galena, Md., in the *Practical Farmer*, gives the following as the results of the honey harvest for 1883, in his locality:

At the beginning of the present season, (i. e. of the honey flow,) the reports from all over the country to the various bee papers were as follows: "Bees bringing in honey very rapidly." "Splendid yield of honey from white clover." "The promise of a tremendous honey harvest," etc. The outlook was very promising, it must be admitted, but the results as we glance at the harvest throughout the entire country have fallen far short of expectations. At the critical period when the delicate white clover bloom was opening to the persuasive influences of the cheering rays from "Old Sol," thus it was that many a bee-keeper's heart was saddened by a succession of cold and dismal rains. To one not acquainted intimately with the effect of atmospheric changes over the secretions of honey in flowers, this may seem a trifling matter. Bee-keepers though, know too well, and oftentimes to their sorrow, the direful consequences of such. Be the bloom ever so fair and brilliant, it takes certain conditions of the weather to enable the flower to secrete honey in abundance. With occasional showers, plenty of sunshine, warm nights, and southerly breezes, the apiarist's heart will be gladdened by a generous flow of honey. If contrary conditions prevail, the reverse will certainly be the case. To some considerable extent the "contrary conditions" have prevailed in many parts of the United States the past summer, and the enormous yield predicted at the start, will not be realized. This is a fact to be borne in mind by those fortunate enough to have good honey in salable shape. Be in no hurry to rush it into the market at ruinously low prices. The demand will probably exceed the supply later in the season, and you may regret a premature sale at only moderate figures.

In some sections where bee-keepers, with an eye to results, have encouraged the growth and perhaps planted such crops, vines and trees as produce honey, the results have been favorable to a good yield, notwithstanding the unpropitious weather. Personally, I have found over an acre of red raspberry vines upon my place, a great advantage to my bees. The honey from the raspberry bloom exceeds in flavor and appearance even the far famed white clover honey. My acre or more of sweet clover and alsike will next year "come in pat" for bee-pas-

turage, even after the white clover is gone. My bees, this year, have averaged over 45 pounds per colony, with which result, considering the nature of the season, I have every reason to be satisfied. Moreover, they are well provided with ample stores for their own use—a fact that is calculated to make the bee-keeper feel peaceful about the region of the heart. If asked "Does bee-keeping pay?" I should answer, in the light even of this year's experience, (which may be termed only ordinary,) "yes, 100 per cent. on the investment."

Beeswax, that "Wiley" Story, etc.

The following is taken from the *Indiana Farmer*, and concerns bee-keepers generally:

EDITORS INDIANA FARMER:—The following is taken from the *Indianapolis Journal* of Oct. 17:

"Do you know where I can get some beeswax?" inquired a wholesale druggist of the reporter. The *Journal* man didn't know. "It's mighty scarce," continued the druggist. "I want genuine wax, suitable for pharmaceutical purposes. Honey is plenty and cheap, never was cheaper than now. Honey men now pour out the mellifluous product and put back the comb. Then there's a practice of making artificial comb out of paraffine, which is growing in favor. This saves the bees the labor of making comb, and they put in all their time making honey. They don't have to go out and roam around, hunting up flowers, either, as the practice now is to feed them on glucose. As the yield of wax is light, there are a number of sophistications. Japan wax is the chief of these. It is white in color, and a vegetable product."

The question is, does the *Journal* man know anything worth speaking of? How much do you think this item helps genuine bee-keeping? I wish you would try and enlighten the reporter a little.

F. R.

The *Journal* man is not so much to blame, for he has seen this same information going the rounds of the press, in some form or another, for the past two years. Prof. Wiley originated it as a "scientific pleasantry." It has proved anything but pleasant to bee-keepers. However, it seems very strange that a wholesale druggist should be led into the same error. The paraffine-comb-filled-with-glucose-story has done the bee-keepers a vast amount of injury. But the immense amount of honey being consumed each year is a fair indication that the people at large are becoming pretty well posted in the matter.

Make all Postal Money Orders and Postal Notes payable at the Madison St. Station, Chicago, Ill.

Are the Bees Prepared for Winter?—The *Indiana Farmer* remarks as follows about the necessity of seeing to the matter at once:

It is to be hoped that all of our bee-keeping friends have their bees nicely prepared for the winter before this, but if any yet remain uncared for, let them be attended to at once. At least see that they have plenty of stores. The indications are that the winter will be an open one, and if such is to be the case, colonies with plenty of stores will stand a fair chance of coming through safely, though otherwise neglected. In many localities the fall drouth cut the honey crop short, leaving many colonies short of stores. Such must be fed or they will surely perish. We would deem it much more humane to brimstone such colonies, than to allow them to die of slow starvation; besides, the honey saved from one, might save the life of another, if given before the weather becomes too cold.

Mr. Jerome Twitchell, of Kansas City, Mo., has worked faithfully for several years in the interests of the honey trade, and has created a market for that health-giving article, in sections where it has scarcely been known as a merchantable commodity before. By his untiring efforts he has built up a trade in honey that aggregated, last season, some 75,000 pounds. His sales, for the present season, already foot up quite large, though he says he has been unable to get as much comb honey as he wants, and he says that he is now largely behind his orders.

He has been netting his shippers 16 cents to 17 cents per pound for choice comb honey in one and two-pound sections, and making his returns in a very few days after receipt. We note that his weekly market reports show a better demand and better prices than any other Western market.

The cashier of the Citizens' National Bank recommends Mr. Twitchell as a thoroughly-reliable, straight-forward and honorable business man. We know that he takes great interest in the honey business, and we are assured that any shipments made to him, or business confided to his care, will receive prompt and careful attention, and meet with quick returns. We take pleasure in encouraging such enterprise as Mr. Twitchell has shown. The producer is compelled to look to some good business-man to market his products profitably for him, and we think that Mr. Jerome Twitchell, of Kansas City, Mo., will fill the bill.

For the American Bee Journal.

Heddon's Report for 1883.

JAMES HEDDON.

As nearly all of the readers of the BEE JOURNAL know, I have run my apiary more largely to experiments than ever before. To the greater benefit of my class of student-apprerices, and to settle in my own mind some unsettled questions, I have, in fact, made my whole apiary one of experiment upon several different mooted questions. Beginning with 133 colonies and ending the season with 298, I have made most of these experiments upon a scale large enough to avoid falling into errors in forming conclusions. The cost in capital and labor, chargeable properly to this experimenting, would reach into the hundreds of dollars; yet I feel paid for that outlay, and if the following report of my conclusions proves of value to the readers of the BEE JOURNAL, I give it cheerfully, and shall feel that I am receiving an additional payment.

My "long term" class, or those who came to stay the 5 months, number 4 men, 3 of whom had already had 3 or more years' experience with bees and modern fixtures before coming here. This class being picked from many applicants, I need not say that all were highly capable of making experiments and forming correct conclusions. To avoid any prejudice that might rest with me, gathered from results of former less extensive experiments, I placed this department in the hands of the class, and the following is their unanimous decision, if I have made no mistake:

The best manufactures of comb foundation for brood and surplus are: 1st, Given; 2nd, Pelham; 3rd, Dandant's Dunham; 4th, other Dunham; 5th, Root. Late experiments with the honey, show the Given superior in regard to the delicacy of the combs in surplus honey. Just here I will add, that justice to all demands that I say, to my own mind, the experiments with comb foundation among the bees was not on a scale large enough to make the decision certain, but the reports given at the Northwestern Convention by Messrs. Oatman, Grimm and others, force me to the conclusion that we are correct in regard to the superior qualities possessed by the Given foundation.

HIVES.—We are unanimously opposed to double walled or chaff hives, and in favor of wired frames filled with foundation; also in filling sections completely with it.

OLD VS. NEW FOUNDATION.—We find that bees work new foundation far more readily than that a year old.

BEES.—We consider the proper crosses of the leather-colored Italians and brown Germans to be the best bees for honey production.

SEPARATORS.—We prefer tin to wood, as being best and cheapest in the end. We prefer the non-separated case to the broad frame and separator system. I will here mention that, for the sake of a comprehensive experiment, we made 300 one-story broad-frame supers (all admitted them to greatly excel the two-story broad-frame super, possessing advantages that no other style of surplus receptacle does,) and used them with 350 of our cases, yet, all in all, we prefer the cases and the non-use of any separators.

SURPLUSAGE.—We prefer the top of the hive, and consider it the only place where it is best to place surplus receptacles. We find the tiering-up system to work admirably, and prefer it to all others.

SECTIONS.—We greatly prefer all dove-tailed sections to any other.

HONEY BOARDS.—After giving this matter a radical and careful test, we find that the bees pass into the supers and cases through the skeleton honey board and double-spaces as readily as where no honey board is used; the sections coming within bee-space of the brood frames. We favor the honey board as greatly assisting in the easy manipulation of the cases.

HALF-POUND SECTIONS.—We find that we can get as many or more pounds of honey stored in half-pound as in pound sections, used either with or without separators. Our experience is that the bees finish them up faster than the larger sizes.

Regarding this system of teaching apiculture, we believe it to be the best extant, viz: to learn, by practice, the ways and means of practical and successful bee-keepers.

In this locality we have not had an average honey season for 3 or 4 years past; the one just passed being the poorest of them all. I do not remember ever witnessing so cold a summer and fall. Not only this, but at one time of year the rain badly over-did the business, while our fall crop was a total failure on account of dronth. Could I have had the season mapped out to me in advance, I would have prophesied—"no honey."

Notwithstanding all, bee-keepers in this section have some, and by improvements in methods of manipulation, we have a crop as good as any of the 3 years past. Our crop report may be found in round numbers on page 528 of the current volume, and it is just that we here add that the fall shortage made room for the fall-feeding of 2,000 pounds of sugar, leaving our credit from the 133 colonies rather a large and healthy increase and about 2,000 pounds of extracted and 4,000 pounds of comb honey, about one-half in one, and the other half in half-pound sections. We expect to use only half-pound sections the coming season, except the finishing up of the pounds now on hand and partly completed.

Our experiments in wintering, which will be made upon an extensive scale and radically tested, are of course still before us and must be left to the decision of my class of 1884 and

myself to report June 1, 1884, when a full description of the tests and results will be given through the BEE JOURNAL.

The season's experiments have not reversed any of my conclusions, but one test has very much modified one of my decisions, which I take pleasure in frankly stating to the reader. We find that separators retard the work in the sections but little, and I now see where my assistant and myself miscalculated when experimenting with separators some 4, 5 and 6 years ago. We used a row of six 5x6x2 sections, with tin separators between each section, and glass at the outside. Like Mr. Turner, we then thought the glassing method a good one. Well, as most of you know, bees are slow to finish off honey next to glass, and when a tin separator stands on the one side and a pane of glass on the other, the foundation between them is often deserted and hardly touched, when many of the inner combs are nearly completed; you plainly see the difference between the sight that presented itself when we peeked through the glasses of the non-separated and the separated sections. The glass was more at fault than the separators, though we learn by this, as well as by other experiments, that separators can in no case be any advantage to work in sections, and in most instances a disadvantage of greater or less amount, according to the other conditions surrounding the apiary, hives and bees.

Advanced apiarists have tested and discarded glass in all forms as connected with the storing of surplus honey, and, I predict, never to return. "History repeats itself," and no less so in apicultural appliances; and long after false and abortive methods have been proven so and laid on the shelves of oblivion by advanced bee-keepers, some of the less experienced, ignoring all that has gone before, dig open the grave and resurrect some of these old errors and ask us to use glass and the complicated, expensive and worse than useless outer cases, that necessarily goes with it, to shut off the daylight. To throw aside the Langstroth space above the frame, that invented and patented claim, which above any other gave us apiculture as a business, deserves the highest condemnation.

Dowagiac, Mich., Nov. 1, 1883.

For the American Bee Journal.

Losses of Bees in Winter.

JAMES POINDEXTER.

History and time often bring to light facts which scientific investigation fails to reach. What do the records of the losses of bees for the last ten years show? First, that the mortality has been greater or less according to the cold or warmth of climate in which they were situated; and secondly, that the losses have been much greater during cold winters than in moderate ones.

Commencing with the winter of 1872 and 1873, a very cold one, great mortality of bees was reported; next, 1874-

75, a similar winter as to temperature, with similar reports of losses; and we might go on and select the cold winters by referring to the *AMERICAN BEE JOURNAL* and noting when the losses of bees occurred.

It has been urged that the excessive humidity of the atmosphere during cold winters was the cause of the losses; if so, then why are there exceptions of those who invariably winter their bees without loss, or nearly so? Would not the natural dampness affect all the colonies alike? While we admit that dampness has much to do in disastrous wintering of bees, we regard cold as being the root of the trouble; by preventing the moisture which emanates from the bees from escaping outside the hive.

Pollen has been mentioned as the cause of losses of bees in winter. If it was, why do some colonies of bees winter successfully, without removing a frame on account of the pollen in it, in preparing them for winter? We pronounce cold the prime cause of the general losses of bees in winter. Is it not a fact that those who winter bees most successfully keep them warm, either by cellar, packing, or otherwise? Has their been substantial evidence offered to prove that cold was not the cause of bee mortality in winter?

Bloomington, Ill., Oct. 15, 1883.

For the American Bee Journal.

The Pollen Theory and Dysentery.

N. M. CARPENTER.

From a rational point of view, the theory that pollen is the cause of dysentery is entirely unreasonable; it is inconsistent with the laws of nature. It is well known that animal instinct leads to those habits which result in the perpetuation of existence, and when man interferes to divert any animals from their natural instincts, the usual result is to weaken the power of self-perpetuation, and the honey bee is no exception to this rule.

If it were not for "the good of the bee" to gather and store pollen in the hive, they would not do it. The interference of man with the natural habits of any animal *never* results in an increase of their power to live. In every department of animal life it seems to be the primary object of nature to give just those instincts, which if not interfered with, will most surely secure and perpetuate animal existence. The idea that the honey bees makes the egregious mistake of putting into their hives just the thing to destroy themselves, is not only a great absurdity, but contrary to all natural law.

Now it is too often the case that when one fancies that he has developed an important theory, every seeming fact which may be made to support that theory is quickly seized upon, while those having an adverse bearing are ignored. In the earlier years of bee-keeping, what bee-keeper has failed to find, when "taking up" an old colony in a box hive, a most disgusting abundance of pollen; and it is

well known that if such hives were let alone, they were likely to winter well and throw out an early and bouncing swarm. It is a significant fact that some of those who are the most ardent advocates of this non-pollen theory are not remarkable for their successful wintering. With my views of the question, I have not hesitated to test the matter in my own practice; and perhaps it would not be out of place to relate a little of my own experience.

Last fall for some reason the broad frames of my hives had the greatest amount of pollen that I have ever seen in a 20 years' experience in bee-keeping. The frames were about one-third full of well-capped honey, and the space below the capped honey, in a large majority of the frames, was from one-half to two-thirds filled with pollen. The size of my frame is 10x13, and in preparing my bees for winter, I gave them only 5 of these frames. I removed no frames on account of the pollen they contained, consequently most of the colonies in my 76 hives were clustered directly upon the pollen. Now, if this pollen theory was correct, I ought to have expected to see my hives pretty well daubed in the spring; but the consequence was that only 5 out of the 76 had dysentery at all, and only 1 of those had it badly; and it is well known that there was a very great tendency to the development of the so-called dysentery all over the country last winter. This is, of course, only one fact; but it bears pretty directly upon the question. I have others of the same nature but will not detail them at this time.

Now, with my views of the question, and with these facts in view, I do not take any stock in the theory that pollen is the cause of the so-called dysentery, which in a majority of cases, is no dysentery at all, but simply a diarrhoea; and I am perfectly willing that Mr. Heddon, or anyone else, should have all the honor there is in fathering this most unreasonable, and I think, unsupportable theory.

Ellington, N. Y.

For the American Bee Journal.

The New Races of Bees.

B. F. CARROLL.

As Mr. Doolittle can enjoy a good thing when he gets it, and can shake his sides in a good hearty laugh at the expense of the ignorant, I want to tell him how much fun I had with a colony of Cyprian bees, presided over by a sister of the queen he has.

Last spring I had a young man to help me divide some bees, and this Cyprian colony was one. Putting on a good veil and a pair of heavy gloves, he thought he was proof; so he shouldered a Bingham "conqueror" smoker, filled with cotton seed that emitted a cloud of smoke, forgetting there was a small hole in his hat. I had got fairly to work when I saw the young man was ready to stampede; seeing a host of angry bees crawling into that hole, I encouraged the young man to stand firm, but they not only found the hole but were using their darts

freely on the young man's head; down went the smoker and off goes the young man to the house with a train of bees after him. I enjoyed this finely, for not a single bee paid any attention to me. I worked on without smoke until I had finished the division.

The queen I let Mr. Doolittle have was from a fine imported queen from D. A. Jones, and was mated by drones from the old A. I. Root Cyprian queen. As these were the only drones in my yard, and as Mr. D. wanted a pure Cyprian, I sent him one of four queens reared in the fall of 1882 (November,) from this D. A. Jones' queen—all 4 were about equal, so far as temper is concerned. From the Doolittle reared 1 queen 20 queens; 10 of these are now in my yard, and these are as gentle as Mr. D.'s or any other Italians.

I have another imported Cyprian that has a somewhat better temper. I now have only 3 colonies of Italians, over 80 colonies of pure Cyprians, and shall keep in my own home apiary none but Cyprians. I opened the colony several times from which Mr. D. got his queen, without smoke, and brushed the bees off the combs to cut out the queen cells, and did not get a sting! I use but little smoke in handling my bees, and I think if Mr. D. would use little or no smoke, he will get along better. I can send him another queen that I think is pure, that is of the gentle kind, but think daughters and grand-daughters from his "Carroll" queen will be an improvement every time. I know these bees to be superior to the Italians, and want no others. My wife assisted me to extract from all, in July and August, without gloves or veil, and did not receive a single sting until we came to the colony of Italians.

As before stated, Texas is the home of the Cyprian bee; they may not do for New York. Syrian bees are, with us, considered good—better than Italians; being a hardier race, they stand our windy springs better. I have tried these bees two years and can say that they are good for Texas. It will not do to handle these bees (Cyprians,) in damp or cold weather. I have opened and carefully examined nearly all of my hives to-day and yesterday, and not an angry bee did I see. I would rather be stung by a bee than to be bitten by a flea. The latter swells my flesh and hurts for hours; a bee sting seldom swells, and in 2 minutes afterward I do not know it. Hang on, Mr. D.; try them one more year. Dresden, Texas, Oct. 17, 1883.

For the American Bee Journal.

One Thing Lacking.

DR. W. G. PHELPS.

The "make-up" of the average periodic bee literature lacks one conspicuous and important feature—simplicity. Of the editorial matter we have little fault to find, but the average contributor seems to delight either in combatting some real or imaginary opponent with ponderous words and scientific phrases or to air his theoretic

cal knowledge with a lot of high-sounding—bosh. Editors, as I take it, aim to publish bee papers that shall be acceptable to the beginner, as well as to the average reader. Who constitutes the average reader? Is he a scientist? Is he a professional man? No; the average readers are plain common sense farmers, artisans and laborers. In saying this I say nothing disparagingly of them, for though owning a professional title, I am proud to class myself among the average readers. What do we want, therefore, as we look eagerly over the pages of the different publications? Do we "hanker" after a "set-to" between Mr. Find-fault and Mr. Cross-grain about the infinitesimal portion of an inch which the yellow bands should be apart on the golden Italians? Are we "almost dying" to know whether a specific microphyte is an existing feature of modern hives? I trow not. If, therefore, the average reader is not; what shall we say of the beginner?

I have seen able practical bee-keepers turn with disgust from the fire-some argumentative articles that too frequently grace(?) the pages of certain bee papers. Not that they failed to understand them, but that they desired more practical matter. When first entering the ranks, some 12 years since, I well remember how eagerly and thankfully I perused such plain and common sense articles as occasionally greet our eye in the columns of the bee papers. Stripped of useless technicalities and scientific terms, they seemed as oases in the desert of matter served up as bee literature. We need *more* just such practical talk, that will actually *teach* the beginners and still prove acceptable to those farther advanced. This is not to be understood as a plea for simple "childish twaddle" in bee papers; but what we do want is the cultivation in writers of that happy faculty of writing wisely, yet in plain everyday language, so that a man, though a beginner, may not err therein. I believe in this that I only emphasize the voice of many readers, and that if the above suggestions were acted upon, several well conducted bee papers would become doubly interesting. "A word to the wise is sufficient."

Galena, Md., Oct. 10, 1883.

Discussion, a Valuable Means of Arriving at Truth.

J. E. FOND, JR.

Discussions on matters of interest and importance are considered valuable in most questions where differences of opinion arise, and, as a rule, are conducted amicably and in accordance with logical and parliamentary rules. In matters connected with apiculture, more than in any others, it would seem that such discussions might be carried on, but I am sorry to see that such is not the case. There always have been and always will be, I presume, differences of opinion existing on theoretical matters, and the

only way I know whereby truth can be evolved and correct notions established, is by full, fair, free, amicable and impartial discussion. Opinions are of more or less value, depending upon the amount of practical experience behind them and the mental calibre of the experimenter.

Bee-keeping as a science can be only learned by study and experiment, and as a valuable aid to the study, come the various reports we find in the BEE JOURNAL from different localities throughout the country. Reports alone of what is done simply,—the amount of honey gathered and the number of colonies kept—amount to but little as an aid; what is desired is to know the process by which this or that result is brought about, the style of hive, form of frame, &c. Right here, however, is where we "run against a snag." If one gives a report claiming the results are owing to a certain frame, or if an argument is made showing up the valuable qualities of the frame, the next issue of the BEE JOURNAL is full of articles which instead of being argumentative, seem written for the sole purpose of venting spite; and why? Simply because the frame praised does not meet the approbation of the writers. The idea some seem to carry is that certain frames ought not to be used, no matter how good results are obtained from them. One writer informs us that a certain frame will not winter bees safely; and when he is informed that bees are wintered safely in them, he says I don't care if they are, they ought not to be; and I once tried to open a hive containing those frames and got stung, while I did not get stung at all in opening a hive containing frames of different style. So goes the battle. I don't know why it is that bee-keepers cannot discuss a question of apiculture fairly; I simply know they do not.

I am sorry that such is the case, as beginners should know what is the best, and the only way to determine that, is to take the statistics and ascertain from them. The discussion does not end with frames, either; else the matter would not be as bad as it is. No matter what question comes up, there are found plenty to oppose; and that too with a vehemence worthy of a better cause. Suppose a beginner wishes to know the best plan of wintering? He naturally looks over a file of the BEE JOURNAL to ascertain the advice given therein, supposing very naturally that he will learn something of value to him; but does he? The poor fellow finds one giving advice in a certain direction; another opposing it at a terrible rate. One advising upward ventilation, another claiming that directly at variance with natural laws, etc., till at last he sits down in despair, saying: "I don't see as it makes any difference; all are wrong and all are right. But what shall I do to save my bees?"

There are matters connected with bee culture on which there is no dispute; there are other matters which are disputed, and which should be discussed in order that the truth may be discovered. These are matters of real

importance, and should be discussed freely and fully. There are still other matters in dispute (and these seem to be the ones on which the most venom is displayed,) which are simply matters of *opinion*, and are of little value, as one way is fully as valuable as another, the question being more one of convenience than of practical utility. These latter questions need no particular discussion or explanation. One man can best operate with one style of extractor because he is most used to it; another prefers a certain style or form of section-case, or wide frame, because he can manipulate it more easily than another; and really it will make but little difference to the beginner which style he does use, but when it comes to the question of what frame shall I use, or what plan shall I adopt for wintering, it strikes me that there is still room for argument. There is a best style of frame, and there is a best plan for wintering. Now let us discuss the matter with all fairness and in an amicable manner, and try to get at the truth, if possible; drop prejudice and opinion, as opinion simply. If you have any arguments, present them, and give others the same privilege, and at last we shall ascertain more nearly the truth than by any other means I know of.

Foxboro, Mass., Oct. 31, 1883.

Essentials of the Coming Hive.

A. WEBSTER.

I have felt a lively interest in the improvement of bee-hives ever since I have kept bees, which is over 25 years. There are many natural laws that have an important bearing on bee-hive construction, but inventors are apt to give undue prominence to one or more points, which are made much of, to the neglect of others which are, perhaps, of equal or even greater importance. Nearly all who have written on "the coming hive," "a standard hive," "standard frames," etc., seem to take it for granted that some one of the hives or frames now in common use should be adopted as such.

I think that advanced bee-keepers in the latter part of the 19th century should do better than that; and look for a hive constructed on a new and scientific plan, and a new system of manipulation and management, that by its adaptation to the natural instincts of bees and the requirements of bee-keepers, shall commend itself to enlightened minds, and not need the formal endorsement of conventions and societies. Those who do not appreciate applied science will, of course, be free to keep bees on Adam's, Samson's, or any other plan they may choose. Of the improvements of the past, movable comb frames must be retained, but of an entirely different construction from those now in common use; and should be *fixed*, and reversible as well as movable. Extracted honey has become a staple article, and its production must be provided for.

Section boxes for comb honey are so convenient and popular, that the best possible system of using them should be adopted; and be of a sufficient number of different sizes to meet the requirements of all—for home use and market—which should be of such proportionate dimensions as to be usable in the same hive without change or alteration of hives.

Comb foundation of pure wax in both brood and surplus departments are too valuable to be neglected, and interwoven wires to hold it firmly in place in the center of frames for brood and extracting, are too useful to be rejected until something better is provided.

□ Cushions or packing of chaff, sawdust, moss or other porous substances, or confined air, may be used to economize heat in cold seasons and climates, and occupy space on the top and on all sides of the brood chamber, used for surplus storage in the honey season, or gained by reducing the size of the brood department to correspond to the contracted size of the cluster of bees in winter and spring.

I will here summarize some of the essential points as follows: It must be perfectly adapted to either large or small colonies of bees, at all seasons and in all climates. To secure this the brood department must be deep and capable of any required amount of contraction or expansion, on all sides alike, by removing or adding comb frames. It must supply abundant room for surplus storage as closely as possible to the brood combs, with free continuous passages. It must be equally adapted to comb or extracted honey; using sections or frames for surplus, as may be required, without change or alteration of parts. It must be easy to manipulate for all purposes, with the least possible danger of hurting or angering the bees. It must be of simple construction, rejecting all unnecessary parts and complications, such as entrance blocks, second stories, division boards, separators, honey boards, cases, clamps, racks, crowders, etc. There are several minor points that I will not stop to enumerate, but all are in harmony with the above.

I am looking for the "coming hive," and shall continue to do so until it appears. To show that looking with me is not idle watching and waiting to see what others are doing, I may be allowed to state that I have at several different times devised, constructed and tested hives that embodied my best ideas at the time, and now have hives in use that seem to be right in plan, and only require to be perfected in the details.

For the American Bee Journal.

Shall we Clip our Queens' Wings?

W. H. STEWART.

It may, perhaps, be thought by some that enough has already been written on the subject of the coming bee, but when we consider that the question of financial success or failure in bee cul-

ture must eventually turn on this one point, we realize that we cannot investigate the matter too closely.

What is the coming bee? It cannot be the common brown bee; the importation of the Italian, and other races of queens in such vast numbers has fixed the fate of the old brown bee. What is left of the pure brown blood must soon be superseded by the various mixed breeds, and soon will only be known in history.

We are of the opinion that it will not be the pure Italian, from the fact that the "new broom" has become somewhat old and fails to "sweep clean." The fever for bright yellow stripes is fast cooling down, and honey producing bee-keepers are beginning to learn that a cross between the different races gives better workers and more honey. Some queen breeders are already awake on this important point and are putting into the market queens that are bred for paying qualities rather than fancy colors; and there can be no doubt but the coming bee will be much superior to any that we now have, if we manage wisely.

It will be well, however, for us all to be mindful that after all the most careful and judicious crossings have been made, we may, by other improper management, defeat the very purpose for which we are laboring. If the bees were left to manage their own affairs, in their own natural way, then the law of natural selection would dictate that none but the fittest would survive; and that "survival of the fittest" means "improvement of the stock." That improvement would be slow, yet it would be sure—all the same. The most prolific queens would produce the most young swarms, and the best winged drones would meet the most queens; and also, the best workers, would produce more combs and store more honey for breeding and winter supplies. But when we take control of them and dictate what shall be their conditions and surroundings, then it is better that we go a little slow and careful, lest we in our eagerness to advance our own present interest or convenience, do a great injury to the bees; for when bees are injured, then it is that apiculture suffers at a corresponding rate.

Longevity is a most desirable quality in the coming bee, and anything that shortens up the *working days* of the bee is all the while sapping the very foundation of bee-keeping. It is well understood that our present bees live from September until April or May following, and be it understood that it is during these cold months that bees in the northern climate are subject to disease consequent to cold and confinement; and yet while struggling against these unfavorable conditions, they are found living 6 or even 8 months, yet in June and July, and a part of May and August, they only live about 6 weeks. Now, why is this great difference in the longevity of bees during the different seasons of the year? It cannot be that proper exercise in the open air is what shortens up their life in summer, for we know that when they are diseased

in winter a good fly in the open air restores health and quietude. This fact alone is ample proof that outdoor exercise is not what shortens up the life of the bee in summer. One writer has expressed his belief that bees in summer work themselves to death. I cannot agree that this can be true from the fact that natural law dictates that all animals live by their own efforts; and we find them prosperous just in proportion as they are able to surmount obstacles and overcome difficulties that they encounter. Labor promotes health, but indolence weakens it.

Each creature is endowed with faculties or members, the functions of which are adapted to the performance of the work of procuring a livelihood, and if any one or more of these members are by accident or otherwise disabled, then the creature labors to a disadvantage, and its life is shortened just in proportion to that disability or inability to procure a livelihood. A proper exercise of any one or more of these members increases their strength and dimensions, but inactivity renders them weak and dwarfed; and long continued disuse reduces them to mere rudimentary conditions.

While the above is true, it is equally true that over-work or excessive strain would injure any member of the bee or any other animal. I hold that incompetent wings and wing power is the chief cause of the shortness of the summer life of the bee. The first indications that such bees are failing in summer, is the torn and ragged condition of their wings. It would appear reasonable to any rational man that if one bee having perfect wings, and another having its wings torn and ragged were at the same locality and a long distance from home, each equally loaded and having to face an opposing wind, there would be a survival of the *fittest*, while the other would perish.

We have no proof that the general health of the worker bee, at the age of 5 or 6 weeks in summer, is more impaired than that of the bee of the same age, in inactive life, in fall or winter; or that the former would die any younger in summer, if it could have perfect wings, than would the latter in confinement. It is true that the former is exposed to birds and storms, but it is equally true that the latter suffers equally as much from confinement and its attendant results.

Let us consider for a moment what we are doing with our bees. Some are expending thousands of dollars and years of valuable time in breeding up bees that show the greatest number of and most brilliant stripes. Others are striving to produce large bodies; others trying to produce tongues long enough to work on red clover; others trying to produce a red clover having shallow tubes to fit the tongue of the bee; others (more practical) are working for the production of bees that manifest the greatest honey-gathering qualities. All seem to be hopeful that they will attain to those desirable ends.

Now please allow me to ask: What would we think of a man that would

advertise that he was trying to raise a superior stock of yellow queens and using black queens and black drones for starters? What of another who was striving for the development of long tongues, and all the while depriving the mother-queens of their tongues? What of another that was working for large bodies, and all the while using the smallest queens for breeding stock? We would pronounce them all crazy, or at least most woefully inconsistent. Are not many bee-keepers (and some who claim to be teachers,) virtually acting just as inconsistent? All will agree with me that a bee may have bands, (or stripes,) color, long tongue, large body, and ever-so-much energy, and yet with feeble wings, or no wings, all these faculties or qualities would be unavailing.

I have thus led the readers along this pathway, over which I felt assured they would willingly accompany me, until we have arrived at our present stand-point. See how hard we are trying to improve our stock, and then what next do we do? Why, we just allow our young queens 5, or perhaps 15, minutes to meet the drone, and then cut off her wing, or wings, and never allow her to fly again. We thus throw her flying members into disuse, and as I have shown, continued disuse renders a member or faculty rudimentary.

Again, all will agree with me that a mother can by no possible means transmit that which she does not possess; and furthermore, that the offspring cannot inherit that faculty or quality which the parent was unable to transmit. If it be asked: How then can the stock be improved? I would answer: An individual, after birth, may, by proper management, have its members or faculties developed to a higher and better condition, and that improvement may be transmitted to its offspring. The improvement of the race can also be made, to a certain extent, by the crossing of the different breeds. If a faculty or member of the individual becomes weak by disuse, then that condition of weakness may be transmitted to the offspring. Disease may be transmitted from parent to offspring; weakness is only another name for disease.

I would ask bee-keepers a question, which they will please answer through the BEE JOURNAL. In view of the above truths, which queen do you think would transmit to her offspring the greatest amount of wing power? The one that is deprived of her wings, and those members all through her life being in a dormant state, or the one that is allowed to retain her wings and compelled to fly as often as circumstances would justify?

If I were offering queens for sale, as superior stock, I would compel the brood mothers to fly often, even if I had to toss them up to give them a start.

Orion, Wis., Sept. 14, 1883.

The Northwestern Bee-Keepers' Society will meet in La Crosse, Wis., Friday, Nov. 16, in the City Hall.

Comb Honey without Separators.

ALFRED GALE AND WIFE.

We will here give our experience in producing comb honey, with and without separators. We got our first one-pound sections in August, 1880, and used separators; about one-half of the combs were more or less fastened to them, and we had to put all that touched the separators back into the hive to be finished up without separators. We tried a few racks the next summer without separators; there was at least one-fourth of them which we could not crate. These we sold at home. This season we had 1,200 pounds of marketable honey, and 200 pounds not finished up, which we kept for home use; and of all this there was not 20 pounds which we could not crate.

Now for the way we did it. We take thin comb foundation, cut in a triangular shape, large enough to go the length of the groove in the section, and kept watch of them after they were on the hive to see that none of them bulged into the others. If there were, we cut it off evenly, and put it next to one with a smooth face. The hollow one, if some of it was capped, we cut the caps off, and put it next to a smooth one, and the bees filled it up nicely. We have sold all our honey; at home we could get only 15 cents per pound.

We took the first honey off on July 10th, and sent a few sample crates to a merchant on South Water street, Chicago, on the 15th; and for this we got 22 cents per pound, and from that to 17 cents, the lowest. We sent 10 crates per week. Just when it was nearly all gone, he wrote to us to send 30 crates per week, as he had places to sell it. We put our honey in twelve-pound crates, having a label on each section; the crates were neatly made, with glass in front, and wedged tight on the back. We had no honey damaged in shipping. If we had 3 tons more we could have sold it all "like hot cakes."

Shelby, Ind., Oct. 18, 1883.

For the American Bee Journal.

The Cause of Fertile Workers.

J. B. MASON.

What apiarist of any note is there who has not been troubled with fertile workers? and which of them can give an absolutely correct solution of their cause? Many theories have been advanced, from time to time, in regard to them, none of which, I apprehend, satisfied their author any more than those who read them. Why, again, is the term "fertile" applied to these egg-laying pests? A "drone-laying queen" is called unfertile, then, why call a "laying worker" fertile when we know it is impossible for it to become fertilized? I trust the term "fertile" will be dropped entirely, and the correct term, viz.: "laying worker" will hereafter be used in its stead. Had the bee-keepers in the past, and

more especially those who assume to be teachers, been more careful in their choice of terms and statements of results, the science of apiculture would be far in advance of what it now is! It befores us, then, to use great care in making statements, and avoid the use of ambiguous or double-meaning terms.

The old explanation of the cause of laying workers, or, at least the way in which they derived the power to become such, was that they were reared in the immediate vicinity of queen-cells, and partook of a portion of the royal jelly, in those cells; this idea or explanation is now fully exploded, and bee-keepers to-day are striving to find a correct solution of the problem. It has been stated that they are only found in a colony that had long been queenless; that only one exists in the hive at a time; that one is revered as a queen when present; that colonies containing these "laying workers" cannot be induced to accept a queen; and many other curious, not to say ridiculous statements have been made in regard to them, none of which are susceptible of proof, and many of which show themselves on the face, to be errors.

I have given some attention to this matter during the last three or four years, and while I have not discovered the real cause of the presence of laying workers in a colony, I have ascertained that they are present, and actually sometimes deposited eggs in the cells when a fertile prolific queen is in the hive. This I have seen several times. I have also seen several "workers" laying in the same hive, at the same time, with no attention being paid to them by the bees.

If the organs of the laying worker from some cause are partially developed, we should expect to see some change in their form by which they could easily be discovered, but such is not the case; the only way in which they can be found, is by seeing them in the very act of depositing eggs. This I have seen many times, and have found no difference in the appearance of those laying, from any other worker. I have found laying workers in a hive that had not been queenless over twelve days; this laying worker being many days, and doubtless weeks old. This last fact does away entirely with the royal-jelly-eating theory, and is *prima facie* evidence that any worker has the power, under certain circumstances, to lay drone-producing eggs.

Queens have been reared at a time when no drones occupied the hives, but ere long drones have been found, and the queen has been fertilized by them; at least no other solution could be given of their fertilization, except that they were fertilized by these drones, and no solution could be given of the existence of these drones, except that they came from the eggs of a laying worker.

In the matter of introducing a fertile laying queen to colonies that contain "laying workers," I regard it just as safe as in introducing to a colony that has just had its queen removed; aye, and even safer, as a rule. It is true,

that exceptional cases may occur, where a colony having laying workers may refuse to accept of a queen, or even a cell; but, does not the same occur at times with colonies that have just had their queens removed?

We must go slow in matters connected with bee-culture; a vast field is open before us from which to glean facts and gain information, and he will prove the most apt scholar who throws prejudice and preconceived notions aside and accepts facts as he sees them. It is very pleasant to start a theory, and then endeavor to bend facts to it, but the better way, and the only one by which truth will be discovered and error rooted out, is to form a theory from well-established facts.

If it is true that some of the new races of bees are particularly prolific with "laying workers," a grand chance now offers itself to make some valuable discoveries in regard to them. Let us all take hold of the work and do "our level best" to find out the truth.

Mechanic Falls, Maine, Oct. 3, 1883.

Prairie Farmer.

How to Secure a Runaway Colony.

MRS. L. HARRISON.

A farmer lately called my attention to a runaway colony of bees that had taken up their abode in a hollow limb of a large maple tree. He said that his adjoining neighbor had recently cut down a valuable tree to obtain honey from a swarm located in it and only obtained about two quarts. This sacrilege certainly did not pay; it takes time to grow trees; moreover honey all mashed with bee-bread, dead bees, rotten wood, dirt and leaves, is poor pay for the labor expended, say nothing of the value of the tree. The limb that contained the colony our attention was directed to, was low, and consequently of little value, and might have been cut off without damaging the tree. If we were going to direct its removal, we should have all apertures leading to the colony securely closed, so as not to be annoyed by angry bees. With this end in view, muslin might be wrapped around and tied securely in place, all protruding limbs and sound wood sawed off, care being taken, meanwhile, not to interfere with their nest. The limb containing the colony should be secured with ropes so that it could be lowered gently, when it is sawed off.

To secure the best results from a colony obtained in this way, set them up where they would be seen when they swarmed, and put the issue into movable frame hives; when they were through swarming, the log might be split open and the comb and remaining bees transferred to a hive, or the limb kept for its yearly swarms and as an object of interest. The fall flow of honey in this locality has been a failure, and if the colony entered the tree late in the season, they have little honey and it would be a pity to destroy them for it. The owner of the tree thought he might put boxes on to

the limb and secure honey in this way, but we should not think this practicable.

A few days since a gentleman called to inquire how to feed a colony of bees in a nail keg. He said that "he had put a box of feed on top, bored a hole, and he could not get them up." We told him to put several spoonfuls of syrup down the hole at night, so as not to attract the robbers, and put a little from the hole to the feed and they would soon find it, and continue doing so and they would come regularly to be fed, like chickens.

Peoria, Ill.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Queries on Hives and Sections.

Will Mr. Heddon please answer the following:

1. Are your hives for 8 frames and 12 inches wide?

2. If you were starting anew would you not turn your frames cross-wise? If not, why?

3. Would it not pay to winter on less frames and shorter ones? My colonies that could not get inside of two-stories in summer, are now clustered in one-third of one-story. This looks bad.

4. Do you prefer a two-story hive for extracting, and how deep should the frames be?

5. Would the Langstroth frame not be much better for nursing bees in spring, rearing queens and extracting, if the frames ran cross-wise? I would not give 25 cents per colony to get my bees insured to winter well, but would give much more to know how to prevent spring dwindling.

6. Would you not prefer perforated metal for a honey board? If not, why?

7. Is the unwired Given foundation as strong as the Dunham when of the same thickness?

8. Will you please tell the best way to mitre the edges of the hives to prevent the wet from warping when tiering-up.

CHARLES MITCHELL.
Molesworth, Ont.

ANSWERS.—1. Our hives are for 8 standard Langstroth frames, and are 11½ inches in width, inside measure, in the clear.

2. By no means; for many reasons. The main ones being that the bees can get at their honey much more readily during the winter than when the frames run crosswise. That with the entrance in the end of the hive we can incline it so as to keep out water and pour in feed, and assist the bees in house cleaning. I prefer to have my bee entrance across the ends of all the frames. The long frames are not only

the most economical in construction, but in their manipulation.

3. No; but it might pay to winter on less frames and longer ones. We are, the coming winter, making experiments upon wintering on different numbers of frames. I should have no fears of the small clusters, they can be wintered as certainly as any, by proper management. They need better protection from the cold, and see that they are clustered in that part of the hive where honey is the most plentiful and bee-bread the scarcest.

4. For my use, all brood-chamber frames should be standard Langstroth. The frames for the extracting super, I would make the same size, if I was producing honey for manufacturing purposes; but if for sweet sauce, I would make them about one-half the depth, working the supers on the tiering-up system, as laid down by Chas. Dadant in his invaluable little work on extracted honey. After two thorough trials, of 32 colonies the first time and 50 colonies the second time, each run two or three years on the horizontal system, I very much prefer the story system of producing extracted honey.

5. In the matter of queen-rearing, I think the crosswise frames have some slight advantages. For breeding bees rapidly, I prefer the standard. It is my opinion that no bees ever "spring dwindled" that could rightfully be called well-wintered.

6. I do not know whether I would or not; am quite sure I would not for comb honey; for extracted, I should prefer it, if I was sure there was no serious drawbacks connected with it. In August we procured four metal honey-boards, and put them to the best test the number and opportunity afforded. We have arrived at some mistaken conclusions in the past, and felt that we wanted more time and more of the honey-boards to satisfy us in regard to that matter.

7. Not quite, I think; as the side walls of the Given are not as high, and much softer, having less pressure, though they contain more wax, but the base being thinner is somewhat weaker. We have not been able to make practical use of full sheets of any foundation in brood frames without the use of wires.

8. For the purpose of shade, we use a board 2x3 feet over each hive. This is generally on the hives during the entire surplus season, but not always, though we use no beveled edges, and have serious objections to them, or any

other device that prevents the lateral motion in adjusting stories. We have never had the water go inside our hives.

Late Breeding, etc.

Does Mr. Heddon allow his bees to fly at all times, or close the entrance when the temperature is so low as to prevent many from getting back to the hive? Why does he object to late breeding? W. L. GAGE.

Kane City, Pa., Nov. 5, 1883.

ANSWER.—I never imprison my bees at any season of the year, except when moving them. Healthy bees, if undisturbed, are in no danger of depleting their numbers by flying from the hives when the weather is too cool for them to return. I am not afraid of late breeding when caused by natural gathering and proper temperature, but fall stimulated-breeding in order to produce bees that can gather no honey during that season, simply to winter them, I object to, on the ground that young bees are no better, if as good, to winter healthfully than old ones, because they are more likely to eat bee-bread during confinement and become sick with dysentery. In late fall and early spring it costs a bee to rear a new one, besides cost of feed and labor. Finally, past experience and observation has taught us that bees winter no better after falls of late breeding than when they ceased early.

SELECTIONS FROM OUR LETTER BOX

Hedge Hyssop, etc.

I send by to-day's mail 2 plants for names. The 1st, No. 1, is a plant having 1 or 2 stalks from the ground up, one of which produces numerous pods, such as I send. The stalk is square and has grown this season to a height of 3 or 4 feet. It was planted under the impression that it was Simpson honey plant.

No. 2 is, I suppose, the true Simpson honey plant, or carpenter's square, so often described. Both grow wild, and from their appearance I should judge them to be good honey plants.

I have 10 acres sown in alsike clover, which, if mown at the proper time, will come in after white clover. The yield from the latter during the past season was immense, and of excellent quality. The drought has cut everything short since the 1st of July.

N. H. ROWLAND.

Keene, Ky., Nov. 17th, 1883.

[No. 1 is *Laphanthus nepetoides*, or Hedge Hyssop, a tall growing perennial plant belonging to the mint family, and a good honey-producer.

No. 2 is *Scutularia nodosa*, the scull-cap or Simpson's honey plant, every where noted for its great yield of honey.—T. J. BURRILL.]

The Hodgson Rack.

Allow me to say to Mr. J. C. Thom and others, that my time is so fully occupied, professionally and otherwise, that I cannot give a fuller description of the section rack I use, until I get my bees into winter quarters. The cut in the BEE JOURNAL of Feb. 14, page 96, may give some additional information, though there are no boards marked E E E, as in description there. The "Simplicity," or Hodgson rack, is the one I have been using for 3 or 4 years past. I think a cut of the different pieces separately, with an explanation thereof, would be all that would be necessary to a correct understanding of this rack, after what was said in my last article in the BEE JOURNAL, page 514. I believe Mr. J. C. Thom will find that when the section next the glass is ready to remove, that all the rest are ready also, almost invariably.

T. E. TURNER.

Sussex, Wis., Nov. 2, 1883.

Bee Hawks.

I send three specimens of the insect genus. For the want of a better name, I, in my nomenclature, call them "bee hawks." I do so from their manner of taking in my bees. I have watched them closely, and noted the precision and fatality of their dart for the alighting board. They will poise themselves upon a twig, near the hive, just as our blue rifle-tail hawk does, ere he makes a dart for his prey. This is the only enemy I have found in my apiary.

JOHN A. EMISON.

Mission Valley, Texas.

[This is one of the bee robber-flies, belonging to the genus *Asilus*, but it is not either of the two species more commonly observed at such depredations, neither do I know of any account of bee-killing by this species.—T. J. BURRILL.]

From Northern Alabama.

Almost 2 seasons have passed since I wrote to the BEE JOURNAL, saying that bees were as rich as I ever saw them at that time. That was from tulip or whitewood, (generally called "poplar" here.) The weather turned cold, and continued so until June 10, when the warm weather set in and continued until July 4, and then we had a rainy season until September 15, and then cool weather followed again. I knew the consequences very well, during the coming winter, of "our little fellows' famine." They consumed a considerable quantity of honey during the cold and cool spell, from April 11 until June 10, being nearly 2 months. Nearly three-fourths of the bees were lost by starvation, last winter and spring. I lost about 40 per cent. of mine for the want of food in due time; I was sick in the winter,

and family troubles prevented me from feeding them. I saved only 12 of them. The spring was cool until May 1, then we had a warm spell for 2 weeks, when it became cold again until June 1, when it became warm again. That was favorable for the linden, which gave a good flow of honey, which, when sealed, looks almost like cream. The bees built a good supply of honey-comb last year, and it was valuable this summer. My 12 colonies stored 360 pounds of linden honey; I could have had half as much more if the hives had been uniform in size. I sold my honey at from 10 to 12½ cents per pound. Our local demand for honey is not as good as it was 15 years ago; but I get as much now from linden as I then got from honey dew. We have not had a honey-dew flow since 1877; and but 1 from poplar and 3 flows from linden. The fall weeds bloom all through September; when this month is warm, they collect a great quantity from them. They do tolerably when the weather is warm, for the cool weather arrests the flow of honey from the plants.

JOHN M. RYAN.

Apple Grove, Ala.

More Asters.

I send three plants on which the bees work nearly all the time they are in bloom, which is from 3 to 4 weeks. Please give the common and botanical names in the BEE JOURNAL.

Bunker Hill, Ill. GEO. DREW.

[These are all asters, whose value as honey plants is widely recognized. They are, however, autumnal bloomers only, hence cannot afford the bee pasturage that some others do. They are seldom cultivated for this purpose, and in a wild state, only grow where they are undisturbed from year to year, as along the fence rows or in open grounds not closely pastured.

No. 1 is *Aster laevis*

No. 2 is *Aster ericoides*.

No. 3 is also an aster.

T. J. BURRILL.]

Details of My yield of Honey.

I see on page 506 a request from T. J. Tiffany for a detailed report of the big yields. To answer his question in full would take too much space, but I will say that I obtained an average of 265 pounds of extracted honey from 10 colonies in 1882, and 150 pounds average from 20 colonies this season, and I am satisfied that the sequel was in feeding. I use the two-story Langstroth hive, 20 frames, for extracted honey. In 1882 I fed sugar, 2 pounds to 1 gallon of water. In 1883 I fed honey, raising a frame from the lower story, uncapping it, hanging it in the upper story, and putting on empty combs in the centre of the brood nest. If there is no honey in the lower story I uncap a comb that I have for that purpose, and hang it in the top story and turn down one corner of the blanket to let the bees pass up to it.

WM. MALONR.

Oakley, Iowa, Oct. 15, 1883.

A Curious Freak.

In the *German Bee Journal*, of Nordlingen, No. 19, volume 39, I read the incredible but true fact that a Mr. Anton Kremer, school director and bee master in Schroda, Germany, saw on July 20th, at 3 o'clock p. m., on an open space of ground, a drone which was dragged along by a worker bee. In going near to examine the pair, he found that they were closely hung together, a drone and a worker bee; that the drone was dead and had its genital organs fastened in the vagina of the worker, so that by gentle pulling they could not be separated. He placed the pair in alcohol, but the worker was strong, and it required several dippings under before it was dead; then on recommendation of the editor of that journal, Mr. Kremer personally delivered the pair to the Rev. Pastor Schonfeld, the greatest scientific and practical bee-keeper in Germany, to investigate, and he sends word to the above paper that "*the bee which hangs together with the drone is not a small queen, but a real worker-bee.*"

The bees are of the common German race. The above paper will publish the result of the investigation as soon as it is accomplished. Rev. Schonfeld is in possession of a very great microscope, which the bee-keepers in Germany bought by subscription and placed in his hands.

Wm. F. KANZLER.

Fulda, Ind., Nov. 3, 1883.

Good Enough.

My report is as follows: Fall of 1882, 71 colonies; lost 6 in wintering, lost 4 in spring, sold 1; balance, 60. Fall of 1883, 115; comb honey, in sections, 2,300 pounds; extracted honey, 4,200 pounds. The spring was wet and cold; clover commenced to yield honey on June 3rd, and it was of good quality. Swarming commenced June 5th, and ended July 4th. Fall crop rather light.

S. H. MOSS.

Colchester, Ill., Nov. 6th, 1883.

The Thickness of Sections.

I have just been reading on page 564 what Mr. A. J. Fisher says about the thickness of sections, and will give my experience. Several years ago I tried the wide frames, to hold 6 or 8 two-inch pound sections, with separators, but I soon found that they were too much bother and would not pay, so I have been using a "case" with a bottom in it, though I prefer a case like Mr. Heddon uses. I also wanted to use, during the past season, thinner sections, so that the combs would be built straighter. I have used 8,000 sections $4\frac{1}{2} \times 4\frac{1}{2} \times 1\frac{1}{2}$. I like them very well, but find that they weigh, when filled, 18 ounces. As I prefer $1\frac{1}{2}$ inches for the thickness of the sections, I would suggest that the size be $4\frac{1}{2} \times 4\frac{1}{2} \times 1\frac{1}{2}$ for those who can use them on their hives; those who use Langstroth hives are all right, with the Heddon case of 7 sections to the foot, $4\frac{1}{2} \times 4\frac{1}{2} \times 1\frac{1}{4}$, scant. If $1\frac{1}{2}$ inches is the proper thickness, the sections might be made $4\frac{1}{4} \times 5 \times 1\frac{1}{2}$; the Heddon case would then hold 32 one-pound

sections, or the 8-frame Langstroth hive. I find that foundation that is made thin enough will sag and warp, so I use guides $1\frac{1}{2}$ inches by the full width of the sections. I do not consider the Given foundation thin enough to use full sheets in the sections; it will not be as thin and nice as natural comb. I fear it will fly-and-by be worth less in the market, if people know it. R. S. BECKTELL.

Three Oaks, Mich.

Gone to Florida.

I came to Florida via sailing vessel from New York to this place, thence to Palatka, Astor, Ft. Mason, Eutis, Tavares, in Orange Co. Built a sailboat, came the entire length of the Ocklawaha river to the mouth of the St. John's, and then back to this place. I secured 80 acres in Marion Co., near Orange Spring, the only place in the interior that I found honey plentiful and bees common and cheap, with palmetto and other honey-producing plants in abundance. Having traveled by water about 400 miles, from the head of Lake Dora to the ocean, camping out during the entire journey, I have suffered less from the heat and insects than at the north, with good health since my arrival.

JNO. Y. DETWILER.

Jacksonville, Fla., Nov. 5, 1883.

My Report for 1883.

As I could not be present at the late Northwestern Bee-Keepers' Convention, and add my report to the others, I will do so now. I commenced the honey season with 80 colonies, but few of them being in an average condition. I had about 3 weeks good flow from white clover, none whatever from basswood, and less than a week's good yield from buckwheat and fall flowers. The season, on the whole, was less than an average. I now have 155 colonies in winter quarters; I have taken 9,800 pounds of honey, mostly extracted; about 3,000 pounds of it being on hand. In addition to the above, I have about 300 pounds stored away in frames for feeding next spring, if needed. My honey has nearly all been disposed of at wholesale, bringing from $7\frac{1}{4}$ to 12 cents per pound, net; averaging fully 10 cents net. As I have been to no expense for new hives or other supplies, it leaves nearly all my income as profit. This makes a fair show for the poorest season I have had in 4 years.

O. O. POPPLETON.

Williamstown, Iowa, Nov. 2, 1883.

Large Oaks from Little Acorns.

I was much pleased to notice in the *BEE JOURNAL* of Nov. 7th, the item concerning the good work Dr. B. F. Hamilton, of Terre Haute, Henderson Co., Ill., had done for the *JOURNAL*. About one year and a half ago I had business in the village of Terre Haute, and met, for the first time, Dr. Hamilton. At that time I discovered that the doctor had an attack of "bee fever," and for a favor which he did me, I proposed to send him the *BEE JOURNAL*, free, for 5 or 6 months.

My proposition was cordially accepted, and the *JOURNAL* was sent on its mission of love and usefulness. Shortly after I ordered the *JOURNAL* sent to the doctor, he wrote me telling me how much pleasure he experienced in perusing its well-filled columns, and I felt certain that the doctor was enlisted for life in the good cause. I am happy to learn of Dr. Hamilton's success in securing subscribers to the old reliable, and can only say to others, "go and do likewise." There is my doctor, for a fraternal shake, with the hope that one of the happiest hours of your life was when you became a subscriber to the *BEE JOURNAL*. J. R. BAKER.

Warsaw, Indiana.

Bees in Good Condition for Winter.

I am preparing my bees for winter. I have 31 colonies and the most of them are in good condition. This has been a very bad season for honey; I got plenty of increase, but only about 200 pounds of honey. WM. ASHCUM.

Ligonier, Pa., Nov. 6, 1883.

The Michigan Convention.

DEAR MR. EDITOR:—May I ask you to call special attention to our next annual meeting to be held in Flint, Dec. 5 and 6, of the Michigan Bee-Keepers' Association. We expect to have by far the best meeting ever held in the State. It is expected that the Rev. L. L. Langstroth will be present. To see and hear him will pay any one for the trouble and expense incident to the journey. We also expect D. A. Jones, A. I. Root, C. F. Muth, and hope to have C. C. Miller and T. G. Newman. From what I hear, Michigan bee-keepers are to be out in force. Hotel rates are to be \$1.00 a day. Further particulars as to programme, will be given soon. We expect to get reduced rates on the railroads. To aid in this, and that I may know how many certificates on railroads to ask for, will every one in this or other States who expect to come, drop me a card at once to that effect?

A. J. COOK, President.

Lansing, Mich., Oct. 15, 1883.

P. S.—I got the date of the above Convention wrong, in a previous notice. The date should be Dec. 5 and 6.

A. J. COOK.

It certainly seems reasonable that a specialist who gives his constant attention to chronic diseases, should acquire a valuable experience and a proficiency which should make his opinion of especial value. Therefore, those who have long suffered from ill health, or merely felt themselves "out of sorts," and have failed to get relief from advice of home physicians, should take advantage of the liberal offer of free consultation and advice made by Dr. E. B. Foote, of 120 Lexington Ave., N. Y. City. A practice of over thirty years, enables him to discover at once the nature of obscure affections, and to offer suggestions for cure or relief which are sure to be plain and direct to the point.—*Adv.*

Special Notices.

Examine the **Date** following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy **5** cents, postpaid; per dozen, **40** cents; per hundred, **\$2.50**. **500** will be sent postpaid for **\$10.00**; or **1000** for **\$15.00**. On orders of **100** or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper, shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter, on your label, notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a statement of account every week.

Our New List of Premiums.

Getting up Clubs for 1884.

To increase the number of readers of the BEE JOURNAL, we believe, will aid progressive bee-culture and help to elevate the pursuit. We, therefore, offer the following premiums for getting up clubs:

While no subscription to the BEE JOURNAL will be taken for less than the regular advertised prices (viz.: Weekly, \$2.00; Monthly, \$1.00),—any one getting up a club of two copies, or more, may select from "OUR BOOK LIST" anything therein named, to the amount of 15 cents for every dollar *they send direct to this office*, to pay them for the trouble of getting up the club; and these books will be sent, postpaid, to any address desired.

For a club of 3 Weekly or 6 Monthly and \$6.00, we will make an *additional* present of a Pocket Dictionary, bound in cloth, containing 320 pages.

For a club of 5 Weekly or 10 Monthly, (or a mixed club of both,) with \$10, we will, in addition to the 15 per cent, present a copy of the AMERICAN "POPULAR" DICTIONARY, comprising every word in the English language that enters into speech or writing; it contains 32,000 words and phrases, 670 illustrations and 512 pages; it is nicely bound in cloth, and will be sent by mail, postpaid, to any address desired.

For a club of \$20,—10 Weekly, or its equivalent, we will present, besides the 15 per cent, a tested Italian queen.

Announcements for larger clubs will be made hereafter.

Subscriptions for two or more years for one person, will count the same as each year for a different person.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Trial Trip, until Dec. 31.—25 cents.

Wishing to be able to reach several thousands of the old-fashioned bee-men, and by the aid of the BEE JOURNAL to lift them up to higher ground, adopting newer methods and progressive ideas, we make the following very liberal offer: We will send the Weekly BEE JOURNAL till Dec. 31, *on trial, for 25 cents*. In order to pay for getting up Clubs, we will give a copy of Fisher's Grain Tables, or Scribner's Lumber and Log Book, to any one who will send us five trial subscriptions (with \$1.25); for a club of *ten* we will give a cloth copy of Bees and Honey; for a club of 15, a cloth copy of the 7th edition of Cook's Manual of the Apiary; for a club of 25, we will present both the Manual and Bees and Honey. If any one wants these Books for nothing, here is an excellent opportunity to get them for a little exertion.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for ten cents.

The new two cent rate of postage for letters went into effect on October 1. Three cent postage stamps will now be but little used. For all fractions of a dollar sent to us hereafter we should prefer either *one-cent*, or else five or ten-cent postage stamps, or a Postal Note. Do not send coins in any letter.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey instructions on the exhibition of bees and honey at Fairs, etc. This is new 10 cent pamphlet, of 32 pages.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL.
Monday, 10 a. m., Nov. 12, 1883.

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The demand for comb honey is fair with a fair supply. Offerings of extracted honey are plentiful, and there is a large supply on the market. The demand is slower than last season, but appears to be improving gradually. Choice comb honey brings 12@15c., and extracted 7@9c. on arrival.

BEESWAX—Is of ready sale at 28@30 on arrival. CHAS. F. MUTH.

NEW YORK.

HONEY—White clover and basswood in 1 and 2 lb. sections, 17@21c. Dark and second quality, 14@15c.; to 2 lb. sections, 16@18c. No demand for dark comb honey. Extracted honey is bringing 8@10c.; 9@10c.; dark, 8c.

BEESWAX—Prime yellow, 27@29c.
H. K. & F. B. THURBER & Co.

CHICAGO.

HONEY—The demand for honey is good. Choice 1 lb. sections of white comb, well filled, brings 18@20c.; 1½ to 2 lb. sections, 16@18c. No demand for dark comb honey. Extracted honey is bringing 8@10c. per pound, according to body, color and flavor.

BEESWAX—Prime yellow, 33c.; medium, 28@30. R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Market is well stocked with ordinary qualities. Inquiry for the same is not active. For fancy comb it is an easy matter to secure custom. White to extra white comb, 16@18c.; dark to good, 12@14c.; extracted, choice to extra white, 7½@8½c.; dark and candied, 6½@7c.

BEESWAX—Wholesale, 27@28c.
STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Choice in better demand, but unchanged. Sales chiefly in a small way. We quote strained and extracted at 6½@7c. Comb at 14@16c.

BEESWAX—Readily salable at 28@27 for choice. W. T. ANDERSON & Co., 104 N. 3d Street.

CLEVELAND.

HONEY—Choice honey is in excellent demand now. Every lot received thus far in good order, has been sold on arrival; best 1 lb. sections bringing 18c. quickly, occasionally 19c.; 2 lb., 17c. with an occasional sale at 18c. Second quality and broken lots are very hard to sell. Extracted honey not in demand.

BEESWAX—28c.
A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—We quote extracted honey at 10@11c., with a good demand. We have sold easily four times as much extracted as we ever did before.

BEESWAX—We have none to quote.
BLAKE & RIPLEY, 57 Chatham Street.

KANSAS CITY, MO.

HONEY—The demand for comb honey is still largely in excess of receipts, and prices fully sustained. Choice 1 and 2 lb. sections, 17@18c. Some extra fine lots have brought 19@20c. On extracted honey the market is well supplied, sales running from 7@8c., according to quality and condition.
JEROME TWICHELL, 536 Delaware Street.

It would be a great convenience to us, if those sending us Postal Notes or Money Orders, would get the issuing Post-master to make them payable at the "Madison Street Station, Chicago, Ill.," instead of simply "Chicago." If they are drawn on Chicago, they go to the general office, and we have to make a trip of six miles to get them cashed; when if they are drawn on the Station as above, it is only a few steps from our office. When sending us money, if you will please remember this, you will much oblige the publisher.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

We need the numbers of the BEE JOURNAL for August, 1866, and April, 1876. Any one having them to spare, are requested to send us a Postal Card. We will give 25 cents for each. Do not send them without writing, for we want only one of each; and, if we are not already supplied, we will take them.

It must be understood that, should an advertiser desire to cancel an unexpired contract, he can do so only by paying regular rates for the number of insertions his advertisement has had.

When in earnest it is quite surprising what a man can do. Dr. B. F. Hamilton, a well-known physician and surgeon of Henderson County, Illinois, has sent us 27 new subscribers. If all those who have a little leisure would do as much in proportion to the busy Doctor, what a "boom" we should have! The Doctor has received as premiums quite a number of excellent bee books. Those who want to add to their libraries, will now be able to do it, for a few hours work in getting subscribers for the BEE JOURNAL. Who will try?

LATER.—Mr. D. G. Parker, one of the wide-awake bee men of Missouri, has sent us 39 new subscribers. They are rolling in at about a hundred a day. All those who are thus devoting a little time to the matter, have our thanks as well as the premiums. See a new List of Premiums on another page.

Vandervort Comb Fdn. Mills,
Send for Samples & Reduced Price-List.
324 Bt J. VANDERVORT, Lacyville, Pa.

Sweet Clover

AND OTHER SEEDS.

Having a LARGE stock of SWEET CLOVER SEED. I can fill orders at 25c. per pound 53.25 per peck, or \$12 per bushel.

Also, all other SEEDS for HONEY PLANTS.

BEE SWAX WANTED!

HIGHEST Market Price Paid.

Please state Quality and Quantity.

JAMES HEDDON,

DOWAGIAC, MICH.

One Dollar per Copy.

The first and second editions of the HANDY BOOK comprised 2,000 copies. We have a few books left which we will mail to any address, if called for soon, for \$1.00 per copy. The Book contains 216 pages—is printed in clear, large type on best paper, and is neatly bound in cloth. We have not put the book in the hands of dealers, as we chose to sell it to our customers with other goods, which we sell at prices very near the cost to manufacture them. To those who paid \$1.25 for the book, we will, on receipt of 30c. in stamps, mail one of Locket's Perfection Bee Feeders, Handy Book and Feeder, by mail, \$1.50. Send the money at my risk. Do not pay 10c. to register it. Prospectus and special circulars describing three new and useful articles for the apiary, sent to any address. Make Postal Notes and Money Orders payable on Salem, Mass., P. O.

HENRY ALLEY,
4402t WENHAM, MASS.

A NEW HIVE

Arranged for continuous passage ways and continuous combs, so that greater ease and rapidity in the handling of sections is gained, also a larger production of comb honey. Although patented, a legal right to make and use will be accorded to any one purchasing a sample hive, the right only to manufacture to sell or convey to others being withheld. A stand, alighting board, entrance blocks, two division boards, ten brood frames, 32 1 lb. sections and the improved section fixtures, all packed in the hive. Price of first hive, including the above parts and a special circular on the mode of management, \$7.00. A fine photo sent for 8 two-cent stamps. Orders filled in turn.

Reference: Exchange Bank, New Philadelphia.

Address, DR. G. L. TINKER,
4440t NEW PHILADELPHIA, O.

Honey! Honey!! Fruit!!!

Twenty nice black Tartarian CHERRY TREES, by express, for \$1.00. These are 3 feet—over and under: can send 20 small ones by mail, post-paid, for \$1.00. CHAS. KINGSLEY,
4542t GREENVILLE, Greene Co., TENN.

Weekly Bee Journal,

DEVOTED TO THE INTERESTS OF THE PRODUCERS OF HONEY.

VOL. XIX.

CHICAGO, ILL., NOVEMBER 21, 1883.

No. 47.

GOLDEN BEE PAPER
THE AMERICAN
BEE JOURNAL
ESTABLISHED 1865

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

From a recent letter, we learn that Mr. Frank Benton, late of the Michigan Agricultural College, but now residing at Munich, Germany, intends to make another journey to Cyprus, Syria, etc., for the purpose of obtaining pure bees from those countries, for breeding purposes. He leaves Munich in January next, and intends to return there in April, 1884.

We have received one of Mr. T. J. Cook's new bee brushes, intended for brushing the bees off the combs, which we have placed in our museum. A letter just received from Mrs. Cook states that Mr. Cook died on Monday, Nov. 5, 1883, but giving no particulars. The BEE JOURNAL condoles with the bereaved in their affliction.

The Florida Enterprise thinks that the happiest set of men in the vicinity of New Smyrna are apiarists, and says: "Olaf Oleson has extracted over 40 barrels of choice honey, and was compelled to stop for want of barrels, and is now gathering it in neat one-pound sections. R. S. Sheldon comes next, while his neighbor, Dr. Goodwin, has been busy building up his apiary for the coming season. Messrs. Rowly, Hart, Brown, Lewis, and others have no reason to complain."

"Trichina; their microscopy, development, death, and the diagnosis and treatment of Trichinosis," by W. C. W. Glazier, M. D., assistant surgeon, Marine Hospital Service. This is the title of a pamphlet published by the Illustrated Medical Journal Co., a copy of which is on our desk.

Mr. King's Visit to Cuba.

The "*Bee and Poultry Magazine*" for November makes the announcement that Mr. A. J. King, its editor, has gone to Cuba for his health, and to establish an apiary in the Island of Cuba. The following is an editorial on the subject in that paper:

The steamer which carried Mr. King southward, also carried on board 100 full colonies of Italian bees, and all the paraphernalia of an apiary. There was also on board the able apiarist—Mr. Osburn—who is to take charge of them on Cuban soil, and manage the apiary for Mr. Casanova, who believes firmly that it is a paying thing to keep bees, and we agree with him.

Mr. King is going to set out the grounds for the apiary, and see that every thing is working as it should, before he leaves the sunny land. He will be gone two months or more, and will return by way of the Southern States, visiting some of the principal apiaries below the Dixie line.

The following is a letter from Mr. King, since his arrival, and will be interesting to our readers:

SAN MIGUEL, Oct. 23, 1883.

After quite a rough-and-tumble journey, fraught with much inconvenience and full of incidents, which I choose to relate at some future time; we are here 20 miles southeast of Havana, with the bees, all of which came safely with the loss of 4 colonies, and these were lost since leaving Havana.

This is truly a wonderful country, and one which, to all appearances, seems to enjoy one continuous honey flow. The number of flowering trees, shrubs and plants are simply overwhelming, and far beyond my powers of classification. The soil is wonderfully fertile, and produces abundantly from year to year without manure. The face of the country is diversified with hill and dell, and running streams of pure spring water are plentiful. The climate is lovely; no fogs, no frost—but one everlasting spring. Flowers are continuous. The palm, orange, banana, lemon and many other fruit trees producing largely of both honey and pollen. Fruits in all the different stages of development, from the flower to the ripe fruit, are continuous throughout the year.

The inhabitants are, as a rule, rather indolent; as nature produces, unaided, all they need for eating and wearing

apparel. Rains of short duration are frequent, so that everything looks fresh and inviting at all times. Of course there are disadvantages which I will relate in future letters, when I shall have had time to write up the "ins and outs" of Cuban bee-keeping.
A. J. KING.

Frank Leslie's Illustrated Weekly gave a full page engraving, on Aug. 25, of a Bee Farm in Brookfield, Conn. This shows that the "sweet pursuit" is rapidly coming into notice.

COUNT ROBERT OF PARIS.—T. B. Peterson & Brothers, Philadelphia, publish this day, "COUNT ROBERT OF PARIS," being the *Fifth Volume* of their new and cheap edition of "The Waverly Novels," by Sir Walter Scott.

The Bee-Keepers' Magazine is after the first of next January to be the title, and \$1 the price of the Magazine, published by King & Aspinwall, in New York. The Poultry part is then to be dropped.

The Kansas Bee-Keeper is on the first of January to be raised in price to \$1 a year.

Shipping Receipts.—Mr. J. O. Todd, of Richmond, Iowa, asks as follows: "When you ship honey, or any freight on the railroad, and the agent gives you a receipt that they have received your goods, do you hold the receipt or send it to the party you shipped the goods to? Answer through the Weekly BEE JOURNAL." Of course it should be sent to the consignee, so that he can obtain the honey of the railroad company. Some Railroad companies will not deliver goods until the receipts are produced.

We need the numbers of the BEE JOURNAL for August, 1886, and April, 1876. Any one having them to spare, are requested to send us a Postal Card. We will give 25 cents for each. Do not send them without writing, for we want only one of each; and, if we are not already supplied, we will take them.

Honey as a Medicine.—Recipes.

The following recipes, in which honey is one of the principal ingredients, are translated from a recent number of the *Bienenvater aus Bohmen*, by Mr. A. R. Kohnke:

CONSTIPATION.—Honey, especially the solid parts of the granulated, eaten on bread, instead of butter, will have the desired effect. That part of honey which does not granulate, possesses this property in a much less degree.

A sauce made of prunes, boiled and sweetened with honey, is an excellent remedy.

In dangerous cases apply an injective of milk and honey, having the temperature of the blood, about 97° or 98° Fahr.

SUPPRESSED PERSPIRATION. (Taking cold.)—Barley soup sweetened with honey, drank before retiring; or oatmeal soup with honey, drank warm.

ASTHMA.—Grated horse radish mixed with honey; one tablespoonfull taken before going to bed.

CONSUMPTION.—Physical exercise, especially horseback riding before breakfast; the body to be rubbed thoroughly with a woolen cloth, night and morning; bedroom, an upper story, with a window partly open day and night; retiring and rising early; main diet to consist of farinaceous food and vegetables; for drinking, nothing but milk and honey, mixed half and half, either warm or cold.

CROUP AND HOARSENESS.—A gargle made of sage tea, sweetened with honey, or pills made of mustard flour and honey.

WHOOPING COUGH.—A decoction of wheat bran mixed with milk and honey, drank frequently, gives relief.

WORMS.—Before breakfast take a tablespoonfull of honey, or a tea made of peppermint sweetened with $\frac{1}{3}$ to $\frac{1}{2}$ its bulk of honey.

TO REMOVE FISH BONES and similar hard objects which have become lodged in the throat.—Make a large pill of wax, (as large as can possibly be swallowed,) dip in honey and let the patient swallow it.

TO CURE A BURN OR SCALD.—Cover the same instantly with honey, keeping it so until the pain ceases.

From the *Bienenvater aus Bohmen* we learn that at the census taken in 1880 in the Empire of Austria (exclusive of Hungary), it was found that 926,312 colonies of bees were kept, which produced 38,412 metric hundred weights of honey and wax (about 7,682,400 lbs.) representing a value of 2,134,272 florins, or about \$1,067,136. There are 18 large apicultural societies, with a membership of 7,100—and 11 bee-papers are published. The exports exceeds the imports by 4,300 metric hundred weights of honey, and 800 metric hundred weights of wax.

Preventing Honey from Granulation.

Prof. J. W. Colcord, of the American Pharmaceutical Association, gives the following on the above subject, in the *Scientific American*:

Having for several years had considerable trouble and loss in keeping pure extracted honey, on account of its tendency, in a short time (particularly in warm weather), to crystallize, I have been ready for any remedy that was feasible. One lot that I purchased in the comb and strained myself, soon became almost worthless from this cause. Some two months ago I had a small lot that I found crystallized when wanted for use, although I had taken the precaution to cork tightly and put in a cool place in the cellar. It occurred to me to see what would be the result from melting and adding a small amount of glycerine. Placing the bottle in a water bath, I soon had it melted, and added one ounce of glycerine to about $\frac{1}{2}$ pounds of the honey, setting it aside to cool. It has shown no sign of re-crystallization as yet, and I am just using the last of it. I can see no objection to this on the score of adulteration, or any harm from its use. In making simple syrup, I have occasionally found it crystallized in the bottom of the bottle, causing some trouble to remove, and several times have found some chemical change, which has caused an unpleasant odor, which I have not at all times been able to obviate, although using distilled water and the purest sugar obtainable. I have not, as yet, had an opportunity of trying the effect of glycerine, but think it might prove beneficial, and in no way objectionable. I have been accustomed to add a small amount to my beef, iron and wine for a long time, and find it prevents scumming, and, in a large measure, precipitation.

The Michigan Convention.

DEAR MR. EDITOR:—May I ask you to call special attention to our next annual meeting to be held in Flint, Dec. 5 and 6, of the Michigan Bee-Keepers' Association. We expect to have by far the best meeting ever held in the State. It is expected that the Rev. L. L. Langstroth will be present. To see and hear him will pay any one for the trouble and expense incident to the journey. We also expect D. A. Jones, A. J. Root, C. F. Muth, and hope to have C. C. Miller and T. G. Newman. From what I hear, Michigan bee-keepers are to be out in force. Hotel rates are to be \$1.00 a day. Further particulars as to programme, will be given soon. We expect to get reduced rates on the railroads. To aid in this, and that I may know how many certificates on railroads to ask for, will every one in this or other States who expect to come, drop me a card at once to that effect?

A. J. COOK, *President*.

Lansing, Mich., Oct. 15, 1883.

We are sorry to say that we shall be unable to attend.—Ed.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
Monday, 10 a. m., Nov. 19, 1883. }

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The demand for comb honey is fair with a fair supply. Offerings of extracted honey are plentiful, and there is a large supply on the market. The demand is slower than last season, but appears to be improving gradually. Choice comb honey brings 12¢@15¢, and extracted 7¢@9¢ on arrival.
BEESWAX—Is of ready sale at 28¢@30 on arrival.
CHAS. F. MUTH.

NEW YORK.

HONEY—White clover and basswood in 1 and 2 lb. sections, 17¢@21¢. Dark and second quality, 14¢@15¢; extracted white clover in kegs and barrels, 9¢@10¢; dark, 8¢.
BEESWAX—Prime yellow, 27¢@29¢.
H. K. & F. B. THURBER & CO.

CHICAGO.

HONEY—The demand for honey is good. Choice 1 lb. sections of white comb, well filled, brings 18¢@20¢; $\frac{1}{4}$ to 2 lb. sections, 16¢@18¢. No demand for dark comb honey. Extracted honey is bringing 8¢@10¢ per pound, according to body, color and flavor.
BEESWAX—Prime yellow, 33¢; medium, 28¢@30¢.
R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Market is well stocked with ordinary qualities. Inquiry for the same is not active. For fancy comb is an easy matter to secure custom. White to extra white comb, 16¢@18¢; dark to good, 12¢@14¢; extracted, choice to extra white, 7¢@8½¢; dark and candied, 6¢@7¢.
BEESWAX—Wholesale, 27¢@28¢.
STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Choice in better demand, but unchanged. Sales chiefly in a small way. We quote strained and extracted at 6¼¢@7¢. Comb at 14¢@16¢.
BEESWAX—Readily salable at 26¢@27 for choice.
W. T. ANDERSON & CO., 104 N. 3d Street.

CLEVELAND.

HONEY—Choice honey is in excellent demand now. Every lot received thus far in good order, has been sold on arrival; best 1 lb. sections bringing 18¢ quickly, occasionally 19¢; 2 lb., 17¢, with an occasional sale at 18¢. Second quality and broken lots are very hard to sell. Extracted honey not in demand.
BEESWAX—28¢.
A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—We quote extracted honey at 10¢@11¢, with a good demand. We have sold easily four times as much extracted as we ever did before.
BEESWAX—We have none to quote.
BLAKE & RIPLEY, 57 Chatham Street.

KANSAS CITY, MO.

HONEY—The demand for comb honey is still largely in excess of receipts, and prices fully sustained. Choice 1 and 2 lb. sections, 17¢@18¢. Some extra fine lots have brought 19¢@20¢. On extracted honey the market is well supplied, sales ranging from 7¢@9¢, according to quality and condition.
JEROME TWICHELL, 336 Delaware Street.

It would be a great convenience to us, if those sending us Postal Notes or Money Orders, would get the issuing Post-master to make them payable at the "Madison Street Station, Chicago, Ill.," instead of simply "Chicago." If they are drawn on Chicago, they go to the general office, and we have to make a trip of six miles to get them cashed; but if they are drawn on the Station as above, it is only a few steps from our office. When sending us money, if you will please remember this, you will much oblige the publisher.

CORRESPONDENCE

For the American Bee Journal.

How Far Apart Should Bees be Kept to Insure Purity?

G. M. DOOLITTLE.

If any of us have a particular strain of bees we wish to perpetuate, the question will naturally arise, How far must I keep them from other bees, so as to insure that the queens of the desired strain shall not mate with the drones of another kind of bees, thus despoiling all our plans?

That such thoughts are in the minds of the apiarist, is proven by the question often being asked, "How far will a queen go from her hive to find a mate," and other questions of similar import. Replying to such a question as the above, I find this answer given by one who should be authority. "Queens are supposed to go a distance of $1\frac{1}{2}$ to 2 miles if necessary;" but as he says, "are supposed," it is taken for granted that the supposition is based more upon what others think, rather than upon any definite conclusion arrived at by the writer. In this case, however, there is nothing said as to how far the drones may fly, and if we allow the drones to fly as far as the queens, a distance of from 3 to 4 miles would be the distance bees must be kept apart to insure purity.

Another writer who is considered authority on the subject of queen-rearing, makes his views very plain by saying, "There are some who entertain the idea that a race of bees cannot be kept pure unless they are kept isolated several miles from all other races. I have tested this matter carefully and pretty thoroughly during the last 20 years, and have found that one-half mile is as good as a much greater distance."

He then goes on to state the length of time the queen is gone from her hive on her wedding trip, from which I supposed he arrived at the above conclusion. He gives this time as five minutes, from which I conclude that it is supposed that a queen cannot fly over one mile in that time ($\frac{1}{2}$ mile and return), but as will be seen, nothing is said of how far the drone may be able to fly during that five minutes.

Regarding the flight of drones, he says the "drones will sometimes fly a mile or more, but the queens will not," but about how long it takes the drones to fly that mile, nothing is said. But what is to hinder those drones from being that mile from home when the queen gets at the end of her one-half mile. As I see nothing to prevent, it looks as if the author would have to admit that he drew his conclusions blindly, and that he has also left a very weak point in his argument.

Now let us look at some facts, which are always stronger than theories, or anything based upon supposition. Some 20 years ago my father planted

a piece of corn on the top of a high hill, and as the season was quite wet during June and the forepart of July, the weeds were quite rank in the corn during the forepart of August. As soon as through haying, we went into this corn-field to cut the weeds. Every afternoon from about half-past twelve to three o'clock it would sound as if there was a swarm of bees in the air, and at first we looked often to see if we could not see a swarm, but as none was discovered, we concluded it must be flies of some kind, which congregated there to play. At this time there were no bees nearer than two miles from this hill, unless, perchance, a stray swarm might have been in a piece of woodland not as far off. Previous to this my father had kept bees, and had often pointed out the queen to me as a swarm was going into the hive when he hived them, and I knew a drone as well as a worker bee.

One day I was sent to the corn-field alone, and as it was a very warm day, along about two o'clock, I got extremely tired (or, perhaps, lazy), and so I lied down partially in the shade of the corn to rest. As I remained there, listening to the hum of the flies, as I supposed, I thought I would try to ascertain if I could see anything; so, shading my eyes by placing one hand each side of them, and looking steadily up into the clear sky; after a little I could see thousands of living creatures circling in all directions, so swift that at times they looked like a streak of black, shooting across the sky. As I was looking at them, I saw a dozen of these shooting objects give chase after another, and soon overtook it, when their flight was less rapid. Circling around, they came near the ground and stopped on the tassel of a stalk of corn, which stood about a rod from where I lay. I got up at once and proceeded to the stalk of corn, but before I was half way to it, one flew off, which looked to me like a queen honey bee, and the other fell to the ground. Upon picking it up, I found it to be a dead drone. Although at that time I knew little of bee lore, still I had solved the mystery of the humming noise, no longer believing it to be flies which made the noise, but knowing it to be made by the drones of the honey bee.

I now believe that this was a place where the drones and queens congregated, but the facts only show that drones are numerous which fly two miles from home, and from the next fact which I give, I believe that there were drones there from hives five or more miles away.

When I first kept bees there were no Italians nearer than five miles distant, yet occasionally I found that some of young queens would produce "now and then" a yellow bee. My bees were all black when I bought them, and the Italians were introduced five miles away, after I had bought the blacks. The next season a man four miles distant Italianized his whole apiary, and the year following I found nearly one-third of my young queens producing from one-twelfth to one-third of their bees with yellow bands.

Being pleased with the work done by these hybrid bees, I introduced the Italians into my apiary the next year, which, of course, put a stop to my observations, as to the distance queens will mate.

From the above facts I am positive that queens of one race will mate with the drones of other races of bees, unless such are kept more than five miles apart.

Nature has so ordered things that the best results possible to be secured are accomplished by the instinct which she prompts, and thus the queens from one apiary are fertilized by drones of a distant apiary, which secures a cross that prevents in-and-in breeding, and gives us a race of bees capable of doing the best of work. That it would be more to the queen-breeders' interests if it were otherwise, I am well aware; but for the honey-producer and for the perpetuation of a hardy race of bees, the Creator has ordered things aright, in this as well as other matters.

Borodino, N. Y.

For the American Bee Journal.

Iowa Central Convention.

The Iowa Central Bee-Keepers' Association met at Winterset, Iowa, on Nov. 2, at 10:30 a. m. There being but few of the members in yet—adjourned to 1 p. m., when the Convention was called to order by the President, A. J. Adkinson.

The minutes of the last meeting were read and approved. The roll of members was called, and a fair number responded to their names.

The Secretary's and Treasurer's reports were read and approved.

Then came the President's address on Improvements in Bee-Culture; and then the enrollment of members was made, which now numbers 28.

The election of officers resulted in the re-election of all, viz.: A. J. Adkinson, President; J. W. Graham, Vice-President; J. E. Pryor, Secretary, and Mrs. Mary Pryor, Treasurer.

The reports of the different members were given. Although there was not reported as large a honey yield as last year, the bee-keepers of Central Iowa have nothing to discourage them. From 327 colonies, spring count, there was an increase of 148, and these colonies produced 8,115 lbs. of extracted, 1,551 lbs. of comb honey, and 92 lbs. of beeswax.

The plan of wintering was discussed to some extent.

Mr. Thos. Chantry, of Casey, Iowa, being present, was called on to give his plan of wintering in clamps, which was very interesting to all present. He has had very good success so far, wintering on this plan.

Motion was made that our next meeting all bring their dinner baskets, well-filled, and have a general good time, socially.

Adjourned to meet at the Court House in Winterset, on Friday, April 18, 1884.

J. E. Pryor, Sec.

For the American Bee Journal.

Pollen Theory, Bees in Winter, etc.

JAMES HEDDON.

In reply to Mr. Pond, on page 560, I will say that I never meant to claim, when using the word "strain," that I had a "fixed" race or strain of bees. I do not think I have, and I will say here to all, that I am constantly fixing and trying to improve my stock, and always expect to be doing so, whether I use German blood with my dark Italians, or the latter alone. For the production of extracted honey, the dark Italians are good enough, and, all in all, perhaps are excelled by none, but in the production of comb honey I cannot think of parting with a mixture of the German blood. There is no need whatever of bringing in any ill-temper by any such mixture, if properly directed. I fully appreciate Mr. Pond's honest earnestness. I have been right there myself.

I can see no propriety in carrying the pollen discussion any farther. I am, at present, preparing such tests as will satisfy me perfectly in regard to the correctness or incorrectness of the theory, and trust that my simple reports, next May or June, will be all the reader will care to hear from me further upon the subject. Every one can experiment for themselves.

Dr. Tinker opened an attack upon this theory. I see nothing new in his last article worthy of much argument and space. As I am entitled to the last word, I claim the right to correct his mis-statements, etc. Regarding my replies in "What and How," I confine my tone of answers more to what I know than any theory, belief, or hypothesis of mine which I may argue strenuously in favor of, for the sake of getting at the facts underlying our winter disasters, while most bee-keepers are still spending their time telling how many latins they lay over the frames, and which way they are laid, etc., etc. Should the pollen theory prove the correct one, I presume the Doctor will be sorry he has found out the truth, simply because it was not *his* theory.

I have never fed glucose to bees, but if I am rightly informed regarding the results realized by those who have, it has had no influence toward killing bees by any poisonous action, but has produced dysentery, and according to my theory, glucose ranks as much below honey as honey does below sugar syrup, in point of its greater proportion of nitrogen or vegetable substance compared with its oxygen or heat-producing powers.

Regarding packing inside or outside of hives, I have tried both, several times. Neither one prevents dysentery, but the heavier out-side packing giving much better protection, has that much more tendency to prevent and alleviate the disease, and saves lugging about such useless loads all summer.

Yes, I have said for years that I believed that I could winter any one colony of bees with as much certainty as my cow, but cost and trouble being greater than the risk, I have preferred

trying to find out the true cause of dysentery, and then is the time to devise cheap and practical methods of wintering bees successfully with certainty.

I have read, re-read and studied Mr. Cornell's last effort, and think that he deserves the greatest credit for that article. I am of the opinion that he is wrong, and that I am right, and I am further of the opinion that if I am wrong, he is certainly right. I greatly rejoice in feeling that at last we are coming to knowledge of some value. After first admitting that by observation and reading, we are conversant with many facts that seem to coincide with Mr. Cornell's theory, yet I wish to append a few that look rather dark.

Now, first, regarding Mr. Balch's bees, I think he will agree with me that this dampness had been with them for weeks, and that they showed no signs of disease whatever, and from what we know of getting bees out "just in time to save them," we would say these bees could have staid in another month with, perhaps, no signs of disease whatever. I think Mr. Cornell makes a weak point when he ignores our ability to tell the difference between extremely damp and dry cellars "without instruments." Knowing the extreme dampness of Mr. Balch's cellar containing the perfectly healthy bees, I will venture to say, without knowing, that the 149 colonies dying out of 150 were better ventilated than the healthy bees above referred to. We are simply after facts, and through them success. Mr. Balch, will you not let us hear from you upon the subject.

If I am mistaken in regard to the humidity during our warm winters, here is something I am not mistaken about. While bees are dying by whole apiaries in this and other sections of the country, there were dotted here and there individual colonies and whole apiaries that wintered perfectly, showing no signs of disease, without any upward or excessive lower ventilation whatever. Does the "signal service records" show that humidity thus runs in streaks through apiaries and districts? The quality of and bad position in which pollen may be placed in hives, does vary in districts and apiaries.

Mr. Cornell says, "that humidity, cold and confinement, as factors in wintering bees, are based on facts in physical science ascertained and established long before he and I appeared on the scene." If he means these are main causes, which he must, does it not seem strange that we have not yet learned to winter our bees? Pollen as a factor in producing dysentery, was not ascertained and established before Mr. Cornell and I appeared upon the scene, neither is it yet, but I propose to agitate it till I find out whether it is a factor or not, and if it is, establish it; if not, drop it at once and continue the search farther.

Regarding the moisture passing from bees by transpiration and exhalation, perhaps Mr. Cornell has justly corrected me. I took my cue from the

writings of professed scientists, or, perhaps, I may say older writers upon the subject. However, this point does not alter the correctness of either theory, as far as I can discover.

When I said that bees "would not eat pollen when in normal condition," I meant that their instincts would guide them to the proper food for the season, provided they were not environed by opposing influences. To illustrate one such influence: Bees will eat the honey from over and among bee-bread, and leave the nitrogenous tissue-making food and pass on to the more heat-producing food, honey, if too much influence be not brought to bear against such removal. But let cold, intense and steady, surround the cluster, thus making such removal painful or impossible, then, when hunger begins to gnaw, a lesser instinct gives way to a greater one, and bee bread is eaten. This consumption takes into the system matter that rapidly loads the intestines. A strong instinct not to void in-doors, causes the bees to hold this feces until the return of warmth will permit them to go out, and if it does not come disease ensues.

I believe that honey contains vegetable matter in such shape that if cold forces consumption of greater quantities, and confinement prevents frequent voiding that dysentery may result from its consumption alone. Honey differs in that respect, and glucose, no doubt, is worse than any honey. Humidity plays the part of conducting heat, and thus assists the cold (so to speak) in intensifying its effects.

The carbonic acid gas question, I know but little about, but I have known bees to winter so perfectly crowded into little, poorly ventilated apartments that I am of the opinion that that question is our "gnat," and that the "camel" is something else entirely foreign to it. Does it not seem strange that Mr. Cornell should demand immediate experimental proof that the pollen theory is correct, when his theory, that is older than he or I, should have been as yet of no practical value to bee-keepers generally?

We now come to the case of the 10 colonies dying while the 32 left behind all lived. If my pollen theory is correct, the agitation of moving these bees just at that time started them to breeding, which, according to my observation, would be productive of dysentery, because it would rear a lot of young bees late in the season, which would be more inclined to consume pollen, and repeat the fatal mistake of breeding out of season, and would also consume stores that ought not to be consumed. But some one says, "I moved my bees in the fall, and they wintered well." Moving bees does not always stimulate them to breeding, but in some cases it does.

In regard to the excessive dampness found in colonies having died of dysentery, it will be found, upon close examination, together with more extended observation, that the wet, moldy condition is the *effect* of the death, and not the cause.

The excessive death rate which occurred in my dry, well-ventilated and capacious cellar, as before narrated, occurred alike with bees that had and had not upward ventilation. The atmosphere in this cellar, however, was so dry that no wet or moldy combs were found in any of the hives, not even those with the least ventilation. Several hives of bees were tried upon the plan of no upward, but excessive lower ventilation; every one of those died; the only one that came through in perfect, or even good condition, of the three survivors out of 49, was one summered at a distance, and brought into the cellar in mid-winter. This colony sat on a large box with three others, in the same kind of hive, with precisely the same kind of ventilation; and while the other three died with dysentery in its worst form, weeks before spring arrived, this colony came out in perfect condition, with about one-half dozen bees dead on the bottom board. I cannot yet see how the humidity theory can cover this case, and many others well-known to the readers and myself.

Have our readers not noticed that dysentery and breeding are very apt to keep company with each other? Does humidity, cold and confinement, "producing dysentery" and "moldy combs," induce bees to breed in winter? Is it not reasonable to suppose that the handling and consumption of pollen might induce breeding, or that a disposition to breed, necessitating the manipulation of pollen, would be productive of dysentery?

Mr. Cornell slurs my use of the term "guess." Is it not as modest to use that term as to assert that his theory of the production of dysentery is old and well established, and yet we all lose our bees with that disease whenever it rages in our locality? Should he, or both of us, turn out to be mistaken, would it not be as well if he had used the same expression?

Mr. Cornell's request to put the bees on combs of sugar, came too late, and after my bees were all prepared for winter, but, fortunately, I have over 40 colonies prepared just in that way, and if one of them have the dysentery that will end the matter with me, and I will cheerfully join Mr. Cornell in doing all I can to find the disease ambushed on the road he is following.

Last winter, with some 25 out of 50 hives, some 14 inches deep, I tried the experiment of boring holes in the back end, producing a circulation of air across the bottom-board, placing the hives above snow level. I succeeded in getting the circulation, but it seemed to make no difference regarding disease—some had dysentery, and some had not. For more than eight years I experimented on no small scale with different methods of ventilation, both in-doors and out, and could never see that that was the cue to the malady.

Dr. Southard, of Kalamazoo, a clear-headed, close-observing, and quite extensive honey-producer, experimented two or three years with out-door packing, between leaving the board cover tight upon the hives, packing over this with straw and chaff, and removing

the cover, in its stead using burlap with the same packing over this. There is quite a difference in the humidity in the interior of shallow hives where in the one case it has only loose cloth and chaff to obstruct its egress, and in the other an inch of wood, two coats of paint, and bee-glue promiscuously distributed over its surface and to seal the joints.

The Doctor is radically in favor of the tightly sealed hives, and so uses them. Two or three years before I tried the same experiment during two winters, and while colonies died both ways, I fancied I preferred the upward ventilation. Does it not look as though these experiments on our part missed the true cause altogether? I would be pleased to hear from the Doctor on the subject. The ordinary reasoner will see at a glance that comparing one man's success with another in a different field, must be short-sighted or unfair. In this locality, bordering Indiana and the marshy region, we have an excess of bee bread in our hives nearly all the year around, and especially in the fall, from various fall weeds, and dysentery rages in its worst form, there having been but one season in fifteen when our apiary was entirely clear from it. This has given me a good chance to study its nature, though, after all, I may be mistaken.

Mr. Cornell's article, like its predecessors, is prized by me, for whether he has the true theory or not, I always feel as though I know something more of the laws governing human health and proper ventilation after reading them.

The Cause of Swarms Absconding.

W. H. STEWART.

Under different circumstances, how different is the behavior of honey bees. At times, it would seem that their knowledge was almost complete. At other times, and under the most favorable circumstances, it would seem that they were void of even the least degree of discretion.

For many years, many of the most careful and close-observing men have studied their wants, habits and mode of living; and have prepared for them almost every conceivable form and size of hive, in some, of which the bees find more and greater advantages than they can find in any hollow tree, or among the rocks; yet we often see them leaving a hive of the most approved style—turn fugitives, and abscond for the woods or caves in the rocks, where we often find them laboring under the most discouraging conditions.

Sometimes we notice that young swarms of bees seem to gladly accept of an old box or nail keg, and at other times will, in a few hours after being hived in one of our best hives, come whirling out with a perfect rush, and leave in spite of all that we give them.

Now, the question is, why do they thus behave?

I will give a little of my experience with bees, and in doing so, will give one reason why bees thus behave—a reason that I have never noticed in bee books or papers.

I began to try to keep bees about 40 years ago, but many times I failed to keep them. When we only knew how to increase by natural swarming, and using only the box hive, many times two or more young swarms would cluster together on the same limb of a tree, and all would have to be hived in the same box together. That, of course, would fill an ordinary hive. That style of hive usually had two, or perhaps three cross-sticks through near the center of the hive—not for the purpose of supporting this heavy mass of bees, but for a support of the heavy combs that were to be built from top to bottom of the box, which were sometimes quite tall.

But hold! here comes a fine young Italian swarm rushing out of a Langstroth hive, in which they were hived yesterday. Well, we went to stop them, and thought we were smart enough to do so; I have detained other swarms in days of yore, by getting to them before the queen had got out, and lifting the hive from the bottom-board, and setting it down, tight on the grass, and thus detaining what remained in the hive, until those that were out began to come back pretty lively; then I put the hive in place again, and all would go well. But this was a young queen with wings not clipped, and she was out before I got the hive closed (as above), and away she went for the woods with her half of the swarm, and I put the half that I detained in their old original home. They were hived on one frame of young brood from their original home, 4 frames of empty combs, and enough more frames of foundation to fill a one-story Langstroth hive, new, clean, nice, shaded, and with plenty of ventilation at the bottom! Why did they leave? Had they a plurality of queens?

I was going to tell why young swarms leave their new home, and, as I am writing here on my porch and watching the bees at the same time (doing double duty), out comes those crazy bees—the first swarm that I have thus lost in the last 16 years. This is the first swarm that has ever left a hive that I had furnished with a full set of combs of foundation, and I was about to express an opinion that they would not leave a hive thus furnished. I never had one leave where all the frames were filled with foundation, but this had one brood comb.

Sometimes we think that we have become masters of the situation, and then some little circumstance turns up that satisfies us that there are some things that we have not yet learned. But I have learned one reason why young colonies leave their hive, and I will tell it.

Some 16 years ago, on July 4, I stood near a colony of young bees that I had hived the day before. It was very hot weather, and I was fearful that my bees would leave. It was a very large colony, and I had found that those

large colonies were much more apt to leave a hive, than lighter colonies.

I had only been watching them about 5 minutes, when down came a mass of bees (about a quart), making quite a thump on the bottom-board, which was hung to the lower end of the box hive with wire hooks, and open $\frac{1}{2}$ an inch all around, similar to the Oliver Reynolds Vermont hive. As the bees struck the bottom-board they came rushing out, and I thought they would leave; but they soon went back and became quiet. I stood watching about 10 minutes longer, when down came the whole colony at once, and out they went with a perfect rush, and this time they left none behind except the queen, whose wings were clipped at the time that I hived them; she came hopping around on the edge of the bottom-board. I caught her and held her about 5 minutes, while the swarm were gone, quite out of my sight and hearing. I began to think that they had another queen, and had gone to the woods for sure; but they missed their queen, and back they came, and entered the hive again. I gave them their queen, and then all went well.

I began to study over the matter, and came to the conclusion that it was for the want of proper support, which caused the bees to fall from the top of the hive, and that the fall frightened them and made them leave. Only one tier of bees could come in contact with the top-board, and they must start the first comb-building, and at the same time, sustain the weight of the great mass of bees that hung to them, and, as it was very warm, the task was more than they could endure; and when their strength was exhausted, they let go, and all came down together.

I made up my mind that if bees had ample support until they had plenty of combs to hold to, they would stay in almost any kind of hive.

I then got some green bushes, stripped off the leaves and filled the top half of the hive so full, that there was no place but that the small twigs came within 2 or 3 inches of each other. I fastened the limbs of the brush to the sides of the hive with small nails. I hived the next swarm in a box thus rigged and all went well; also, the next, and kept it up until I had, in after years, thus hived over 300, and had no further trouble with absconding swarms.

When foundation came into use, I obtained a mill and began using frame hives. I gave full sheets of foundation, and, as I had no trouble with swarms leaving, I concluded that foundation answered the same purpose in supporting the cluster, that the brush did.

Since I began writing this, I have read a letter in the *Gleanings* for August, by Mr. Doolittle, in which he gives it as his opinion; and also that of Mr. Betsinger, that bees are more apt to leave a hive having a card of brood, than one having only foundation.

Before I used the brush, I had for 20 years lost a majority of my heaviest swarms by absconding, and now, if

the trouble is to come up again, it will be rather a serious matter. Has any one lost bees that were hived on a full set of full sheets of foundation? Let us hear from them.

For the American Bee Journal.

The Improvement of Bees.

L. C. JOHNSON, M. D.

Previous to the introduction into England of the Godolphin and Darley Arabian horses, the breed of English horses was as celebrated for its worthlessness as it has since become (by judicious crossing and selecting) for its splendid qualities.

By breeding from that grand horse, Eclipse, who never was beaten, and whose power of speed seemed unlimited, the English brought up their sluggish breed to be a race of "racers."

By careful crossing, and selecting from the hardy and strong, though not large, Suffolk Punch breed, they have produced the monstrous draft horses of London, which are the wonder and admiration of lovers of horses the world over.

By a long course of careful selecting and crossing from the old domestic cattle of Europe, whose best steers weighed but little more than 1,000 pounds, cattle men now rear steers weighing 3,000 pounds and more. And what is true of horses and cattle, is equally true of other kinds of domestic stock. The magnificent Cochins, the beautiful Spanish, and the tender, luscious Dorking, attest the success of intelligent skill in the crossing and select breeding of the barn-yard fowls.

No successful farmer could be induced to feed for market the long-legged, slim-nosed, slab-sided, empecklers, formerly sold for hogs.

Turning to our fruits and vegetables, we find that high culture, with careful selecting and crossing, has produced marvelous results. From the *Solanum lycopersicum*, common wild tomato, we have developed the magnificent garden tomato which is so justly regarded as one of our very finest fruits. Likewise the potato has been brought up from a worthless hard-woody tuber, to be a food-staple for millions of Earth's people to almost live upon. The strawberry, from a berry no larger than the end of a finger, has developed the monstrous Sharpless, and many other varieties, measuring six inches and more in circumference.

These results have been obtained, not by opposing Nature's processes, but by selecting and perpetuating her best products. The very essence of improvement in either animals or plants, is to develop the good points and banish bad ones.

There is neither animal or plant that offers greater facilities for this than does the honey bee; for, if we have a single choice queen, we may, in a few short weeks, have the entire apiary to consist of her offspring. To accomplish this, we have only to destroy queens whose bees possess bad qualities, and substitute queens reared from our better strains.

If we are to improve our bees, we must first have clear conceptions of the qualities to be desired, in our ideal or perfect bee. Then, bearing in mind the character and qualities of the different races we have to begin with, we are prepared to so manage our apiaries as to produce a better strain of bees than any we now possess.

The "ideal queen" should be large, strong, active, and very prolific, as it depends upon her to keep up a population of from 40,000 to 70,000 insects, whose average life is less than two months during the working season. A strong colony should have at least 60,000 bees, during the June and July honey harvest, and, if their average life is two months, the queen must lay 1,000 eggs per day to keep up the strength of the colony, to say nothing of the thousands that are to be reared for swarming.

The "ideal bee," that such a queen should rear, must possess, in the highest degree, the qualities of energy, hardness and gentleness. Energy sufficient to induce it to gather and store honey, whenever and wherever it is to be found. But some may object, that if we get bees full of energy and vim, they will pounce upon and rob their weaker neighbors. I tell you, nay; for it is not the busy, energetic colonies whose workers go to the fields early and late, and who store up for us 100 pounds and more of nice comb honey who do the robbing. The danger is from those colonies which have thousands of idle bees, lying around all day long. They, like idle people, find some mischief still to do.

Hardiness is an essential quality for this typical bee; its life is a life of labor; joyous and happy it may be, flitting from flower to flower, sipping nectar, "the food of the Gods," from the beauteous cups of Nature's own laboratory, yet the labor is severe and constant, taxing the powers of the insect to the utmost, during the honey harvest. Bees, weighing but $\frac{1}{14}$ grains, often carry home to the hive 2 grains of honey, dropping almost exhausted at the portal of home, only to rest for a moment, then to hasten in, unload and again go to the fields to renew the burden.

Gentleness is a quality only necessary for man's convenience; it is true, we can handle them in spite of their crossness, but it is so much more pleasant, and more conducive to a serene frame of mind, to handle kind and gentle bees. So much for our "ideal bee." Let us now consider some of the qualities possessed by the different races of bees.

There are now, in this country, at least five distinct races of our common hive bee, the Syrian, Italian, black or German, Egyptian and Cyprian. The Syrian queens are wonderfully fertile. I have known them to lay nearly 6,000 eggs in 24 hours; on one occasion, I placed a frame of foundation in a Syrian colony, at 9 a. m., and at 5 p. m. of the same day, I found the cells drawn out, but no eggs; at 2 p. m. of the next day, I removed it and placed it in a queenless nucleus, where it was proven to contain no less than 5,500 eggs, all deposited by one queen

in less than 21 hours! These queens are exceedingly strong and hardy, often being able to fly from the cell as soon as they cut their way out, which occurs in from 12 to 14 days, or from 2 to 4 days earlier than the Italian or German bees.

Their bees come out of the cell in 17 days from the time the eggs are deposited in the cell, or 4 days earlier than do Italians or Germans. This, I think, to be due more to the abundance of food furnished to the larvae, than to any essential difference in their natural time of development. These bees give food in such abundance to the larvae, as almost to cover them, like the queen larvae is covered and floated in the royal jelly, so prodigally supplied in the queen-cells. The Germans and Italians are poor nurses, leaving the larvae to become hungry, until at times they may be seen with their necks stretched and mouths gaping, mately pleading for more of the food which brings them life.

The Syrian bees are possessed of wonderful energy, working early and late, flying far and wide in search of stores; they come rushing from the hive, and are off like a flash to the fields, returning heavily burdened from the fields of toil, they hasten past the threshold of home as though the fate of nations depended upon their speed; and this tremendous activity is kept up all day long. This race has the reputation of being more cross than Italians. This, I think, to be due to their being more irritable on the first opening of the hive, and to the fact that they are more sensitive to any jarring of their hives or frames than are the Italians. The latter stick closely to their combs after a jar, which would send dozens of the Syrian bees upon the war-path.

If proper care and gentleness is used in opening the hive and handling the frame, they are not, I think, any more irascible than are the Italians. In rearing queens, they will often build from 30 to 50 cells upon a single frame of brood. Their fighting qualities abolish all danger of robbing, as they not only seize an intruder before he gets inside of the hive, but they will often dart upon an intruder while a foot or more from the entrance.

The Cyprians are very similar in every respect to the Syrian bees, except they are, possibly, a little more irritable and nervous. They have the same intense energy and combativeness. When once aroused, it is almost impossible to subdue either of these races by smoke. They are, I think, longer-lived than the other races.

The Egyptians are quite similar in appearance to the Italians, only they are somewhat smaller and lighter-colored. Their queens are wonderfully fertile, "breeding all the year around," and, without very judicious management, their owner will get all bees and no honey.

The Italians are the beautiful golden bees which revolutionized our bee-keeping, and, by their gentleness and docility, made scientific apiculture pleasant and profitable. Their queens are more fertile than the Germans,

but less so than the Syrians. The same is true as to strength and hardiness, they, in common with the Syrians and Cyprians, being able to drag out and fly off with the larva of the bee-moth, which was formerly such a pest to bee-keepers. As honey-gatherers, they are almost equal to the Syrian and Cyprian bees; that is, a full colony of Italians and a full colony of Syrians or Cyprians would probably gather nearly equal amounts of honey, but the greater fertility of the Syrian queens give them the advantage by enabling them to have a full hive at the beginning of the honey harvest. In gentleness, the Italians are undoubtedly ahead of any other race, yet this gentleness has a limit, and they may be aroused into a perfect frenzy of ungovernable rage. If attacked by robbers, they form a cordon of guards about the entrance, which effectually bars it.

As to the German or black bees, it is difficult to name any one point in which they excel the yellow races, and yet there are men of no small experience in apiculture, who maintain that they are equally as good as any yellow race. It is claimed by their friends that they are less apt to winter-kill, and that they are better comb-builders and make finer-appearing comb honey.

Now, as to the method of securing the "ideal bee" from these different races, I should recommend that a pure Syrian queen be fertilized by a hybrid drone from the Italian and German races; that is, the drone should be from the egg of a queen whose mother was a pure Italian, mated with a German drone. This would produce a bee one-half Syrian, one-fourth Italian, and one-fourth German.

I would have this much of the German blood, not because I think the German superior or even equal to the yellow races, but because I believe it to be demonstrated fact, that, other things being equal, this admixture of the German blood greatly increases the honey-gathering qualities of our bees.

Another point of equal or even greater importance than the race we breed from, is the character of the queen from whose brood we rear our queens; she should be our very choicest in every respect: size, beauty, fertility, strength and activity; her bees should be tested and proven to be strong honey-gatherers, good comb-builders, full size, and gentle, (the color is a matter of no importance, though I must confess that, other things being equal, I greatly prefer the beautiful golden-banded fellows.)

The drones with which our queens are to be mated, is a matter we cannot absolutely control, unless we succeed in getting queens fertilized in a closed room, which I intend giving an extensive experimental trial next summer; without this, we can, by careful management, control it to a very large extent, unless we have neighbors within a very few rods who have bad bees.

My plan is to select a choice queen or queens such as I desire to breed from, and very early in the spring to place a section of drone comb in the

center of the brood chamber of their colonies, (and I usually have no difficulty in getting them filled with drone eggs.) I then remove them and put some sections in such colonies as I do not want drones from. The bees in this colony now care for the drone larvae, and in due time the drones are hatched and the sections removed. The colony is thus supplied with the right kind of drones, and are satisfied without rearing drones from their own queen. If they attempt to do so, their drone larvae are removed, and more drone brood given to them from a selected queen. I thus have my apiary supplied with selected drones, and very rarely have I had a mismatched queen, although there are dozens of black colonies within half a mile of my apiary. I think if an apiary is properly supplied with drones, a very large majority of its young queens will find their mates from the home yard.

In rearing queens, I place a strip of foundation in a frame, and hang it in the center of the colony containing the queen I wish to breed from, and allow it to remain until drawn out and partially filled with eggs. In the mean time I prepare a strong nucleus of four frames of young Syrian bees, with plenty of honey and pollen, but no unsealed brood. In the center of this nucleus I place the frame of eggs from my choice queen. I thus get the whole attention of my nucleus concentrated upon a comparatively few eggs, and the queen larvae are kept abundantly supplied with royal jelly from their hatching and before, until they are capped over. On the 11th day from the laying of the egg, I remove the frame of cells, without any bees, to a lamp nursery, where, if I happen to be unable to attend to the queens as fast as hatched, they will live peaceably together for several hours. The young queens are at once introduced to queenless nuclei, previously prepared for them, where they remain until fertilized and ready for use. All the small, sluggish and feeble queens are destroyed, and I think I thus secure the best possible results.

If this weeding-out process were rigorously persisted in, other things being equal, I think we would get more uniform results from our colonies, and not have one colony yielding 100 pounds or more of surplus, while another by its side gives only 10 pounds, or even nothing; in other words, perfect, strong, active queens should give us strong, active honey-gatherers.

Finally, whatever race or races of bees we keep, let us breed both our queens and drones only from our very best queens.

Fountain City, Ind.

Straight Combs without Separators.

W. Z. HUTCHINSON.

The width of the sections has much to do with getting straight even combs. To get straight even combs in sections 2 inches wide, separators are needed. The nearer combs approach to the thickness that bees naturally build them, the more perfect they will be. Why are not separators needed between brood combs? Instead of attempting to answer, let producers take a hint and make their sections accordingly.

It is my opinion that $1\frac{1}{2}$ inches is about the best width for sections used without separators; that is, to obtain the straightest combs. The sections that I used last season were 11-16 inches wide; no separators were used, yet every section was crated. Let no one suppose, however, that every section was perfectly true, and would fit anywhere, as would sections built with separators; occasionally a comb would be "plump" or "bulged," but, of course, the adjoining ones would be "thin" or concave; hence, by the exercise of a little care, all was crated without trouble. If a plump section was found finished, and the adjoining ones unfinished, the plump section was removed and its place filled with a partly finished section, or a section filled with foundation, and, in crating, a lookout was kept for "lean" sections; by thus putting together the thick and thin sections, there was no trouble. Nine-tenths of the sections would fit anywhere, and truth compelled me to say that the "bulging" was done by pure Italians. The sections filled by hybrids were like so many "bricks," no crookedness, no bulges, no bear combs, while the cappings were of a snowy whiteness. So marked was the difference in the workmanship of the Italians and the hybrids, that, after the cases of sections had been removed from the hives, and stacked up, my brother or myself could look them over and tell which cases had been filled by hybrids and which by Italians.

I use an 8-frame Langstroth hive, and the Heddon case. The sections stand parallel with the brood frames, and I am careful to have the hives stand perfectly level, except that they are slightly raised at the back end. I have tried putting a small piece of foundation in each section as a "starter," have filled the sections partly full, and have filled the sections entirely full, and I am decidedly in favor of filling the sections full, leaving $\frac{1}{8}$ of an inch at each side of the foundation, and $\frac{1}{4}$ of an inch at the bottom. When the section is filled full of foundation, the cells are drawn out full length next to the wood, and the comb is well fastened in all around the outside, being built out nearly even with the edge of the wood; while, if the section is only partly filled, the cells decrease in depth as they approach the side of the section, and are fastened with only a thin strip of bear comb that is easily broken. The top and bottom bars of sections should be

$\frac{3}{8}$ of an inch narrower than the side bars, instead of only $\frac{1}{4}$, as usually made. This is a greater help in securing straight combs without separators than one would suppose. It seems to induce the bees to leave a greater space between the combs.

There is one other point. The bees should be given the proper amount of room, neither be crowded nor given too much room. When too much room is given, the bees are liable to work first upon one side only, of some of the foundation, and, as a result, it warps and bends. By the way, Dr. Miller, at the Northwestern Convention, said that he thought foundation made upon a roller mill was more liable to warp or curl than that made upon a press, and I am inclined to agree with him. I used the Given foundation, last year, and ask for nothing better.

In regard to the queen being more liable to lay in thin than thick combs, I would say that there is a stay in the growth of even the thickest comb when the queen would be able to lay in it, and if she enters the surplus department, she makes it her business to be on hand with eggs just as fast as the combs are drawn to the proper depth, and it should be remembered that she is capable of laying in a cell that is not much more than $\frac{1}{8}$ of an inch in depth. It is my opinion that the width of sections has nothing to do with influencing the queen in regard to her entering the surplus receptacles.

To recapitulate: Have dark Italians with a dash of the brown German blood, use narrow sections, fill them with Given foundation, have the hives level, and keep the surplus department full of bees.

Rogersville, Mich., Nov. 10, 1883.

For the American Bee Journal.

One of My Experiences.

C. THEILMAN.

On page 542 of the BEE JOURNAL, Messrs. Youngman and Trussell state that their bees have reared drones and queens from worker eggs and larvae, upon which the editor remarks that "it will be very generally disbelieved, that bees can and will rear drones from worker eggs." I have had this summer (for the first time in 14 years of bee-keeping), an experience which I will give, and which satisfies my own mind, that some theories do not always prove correct.

One day in July, I hived a large swarm of pure Cyprians, but on the next day I found that a good many of the bees went back to the old hive, which left the colony weaker than I wished to have them; so I concluded to strengthen them with a second swarm that came out on the next day, knowing that the Cyprians would not be willing to accept them, as I had some sad experience before. On account of their being in the hive for 2 days, I used peppermint, giving them a good spray after shaking them from the frames in front of the hive, uniting the second swarm with them. Before

they were all in the hive, the expected fight had commenced; therefore I renewed the same "shaking-off" performance, without better results; then I gave them a good spray in the hive and let them be, as I had other things to do. The next day I looked for the Cyprians, but found the hive empty with two pieces of worker comb of the size of a hand; one of them was nearly filled with eggs, so I put a swarm, that had just issued, into this deserted hive. The new colony seemed to be contented, as they were working lively.

About eight days after hiving them, I examined and found no brood, except in the piece above described, where there were three queen cells and about 25 capped drone cells (enlarged worker cells), and about 150 to 200 worker cells nicely capped over. About two weeks after, I looked into the hive again and found the brood all hatched; at least the cells were empty and a young queen had just commenced laying.

Now, I leave this case of experiment to the readers of the BEE JOURNAL to judge, whether or not bees can, at their will, rear either workers, drones or queen bees from the eggs laid in worker cells, for the possibility of other eggs being deposited in this piece of comb, other than from the queen of the first swarm, is almost excluded.

The last swarm, of course, was queenless, and therefore provided for a queen and drones.

Thielmantion, Minn., Nov. 7, 1883.

For the American Bee Journal.

Description of My Bee-Feeder.

DR. J. S. MC ALLISTER.

As there has been several descriptions of bee-feeders published in the BEE JOURNAL of late, I thought I would describe one of mine, which I think is very practical, and one that can easily be made by all, especially those who use the American or square frame, with tight top-bars, or bars $1\frac{1}{2}$ inches wide. It can be made either one-half the depth of the frame, or use the whole frame, which I think is best, and then let the bees build comb or draw out foundation in the same, and fill with honey for winter use, the same as any other frame; place it in the center of the brood nest for winter, and use it at any time a feeder is needed. To make the frame and feeder complete, nail a bottom-bar about one-half way up the frame or a little more, which is the same width at the end-bar, which is generally made of $\frac{3}{8}$ stuff. Then take two top-bars and shorten them a little, and nail one on each side of the middle-bar, to form a trough the length of the frame; now bore a hole (about one-half inch hole will do), through the top-bar, and in the hole place a hollow tin tube, long enough to reach very near the bottom of the trough, and your feeder is complete. Very thin stuff for the sides of the trough is the best, as it will not take up as much room. I like it the best of any device that I have ever seen.

By placing a funnel in the hollow tube when filling the feeder, there is no need of spilling a drop. It can be made a ventilator or corked up, when no ventilation is needed, by having the tube run close to the bottom of the feeder; the bees will not pass through it. There seems to be no need of any float, and the bees will not fill the trough with comb.

I think I was the originator of what is now known as the pepper-box feeder, and had some gentleman (I do not remember his name), take one to the Vermont Bee-Keepers' Association, about 15 years ago. I used it with a rim that fit over wire gauze that had been stamped to fit upon the rim, so when used over a hole in the honey board, the feeder could be removed without letting out the bees, similar to the Van Dusen feeder.

Allen Pringle's article on Wintering Bees (page 547) gives many good ideas, and I often wonder why so many recommend doubling-up in the fall, unless they have too many bees or more wealth than they know what to do with, for I never think of destroying a nice Italian queen, if I can find at least four good, full frames of bees to winter her in.

I live in so much of a honey district, that I hardly ever feed. I have increased from 18 to 40 this season, and took about 2,000 lbs of honey. I shall winter on the summer stands, as usual.

Columbus, Neb., Nov. 9, 1883.

For the American Bee Journal.

The Best Bees, Winter Packing, etc.

E. P. CHURCHILL.

This has been one of the best honey seasons here for years, though rather wet and cold in the spring, yet with proper care in early stimulative feeding, I got my bees strong for apple bloom, which they improved; and, as I am in an orchard section, they took in a good quantity of nice honey.

One very important question (which is often asked), is how to control swarming? I know of but two ways, and that to only a certain extent; first, get away from Italians, and work for extracted honey; for when we apply the sections to the Italians, out they go, even often without cells, and when they once get on a swarming rage, who can stop them? And when we come to extract from Italians, they cling to the combs so closely that it is no small job to go through a number of them. Does it not look as though we had gone a little too much for color? I think it has been over-done, many times, though I would not condemn the yellow bees, for they have some desirable points. They are so gentle to handle, beautiful to look at, and stay on the combs remarkably; yet, when we come to shake them over the hive, what then? Instead of dropping off (as some complain that the blacks and hybrids do), they scatter all around the hive, and will not gather in half as fast as others.

It is claimed by some that they breed later in the season than others, but I

fail to see any difference in that respect. Again, the honey capped by them is not as nice as by others (even if they stay to cap it). So, why can any one say they are so far ahead of others?

I have reared queens for my own use from my best hybrids, and until I am more dissatisfied with them, I shall uphold them for their good qualities. The bees are easy to handle, and when I give them a case of sections, I am quite sure to know where to find them.

I believe we are working to disadvantage by using such wide boxes, and also too light foundation. If any one doubts this, let him try a few sheets of thin foundation in brood frames, and see if they will not leave it until they are obliged to use it or go without. I have experimented considerably in this matter, and shall use thicker foundation for boxes, in the future.

I shall also try a few cases with sections only a little more than one inch. I do not believe we know what can be done, any more than Mr. Scoville did, before he tried feeding bees all winter, and reported that they came through wonderfully well, for it has been the old story that bees must not be disturbed in winter. Who knows but that the Italians have more good reasoning powers than to think of accepting those thin sheets of foundation. This may be the reason that the other bees do the best in boxes.

I have been told by a large breeder and dealer in bees, etc., that he paid \$8.00 for a queen, and, after testing her, sold her and a good strong colony for \$9.00, and said they were the laziest bees he ever saw, and the yellowest.

I started with 11 colonies last spring; took 200 lbs. of extracted honey, and as much or more of comb honey, reared 34 queens, and now have 33 good colonies. I have packed most of my bees in a new manner, and will tell you how it is. I slant a good shingle or board, not more than 10 inches wide, in front of the hive, so as to reach up about to the upper story; then I shake bedding or meadow hay all up about the hive, most in front; then I stand a few evergreens, not much taller than the hive, about this; then I tie the butts of two long, slim sticks together, then take these around the whole, and have the tied cords come at one corner of the hive, and then tie the tops together. Now, I have a stay for the whole. I tuck under more boughs, and hay enough to make it perfectly dark, then roll in a few clusters of hay about the upper part, below the cover, and I feel that I have one of the best packings extent. No cold can get into the entrances in windy weather, nor snow to clog the entrance, nor is it so close as to smother them. I open the entrance about 3 inches.

I am using mostly leaves for packing over the bees, and instead of a crooked stick over the frames. I make a rack of two pieces across the frames, one inch from the ends of the hive, then I nail strips on these, so as to hold up the packing. The end strips are about an inch high. These will not throw the division boards out of place. I al-

low the one in at each end for room to crowd down packing, as it is always coldest at the ends, in a movable two-story hive, but I use mostly two-story chaff hives of my own make, and like them best of all.

In this way of packing we can take off the covers, feed the bees, etc., if we wish, and it does away with the great loss of bees by flying, for they are so cool that they do not know what the weather is outside. I think it next to a snow drift, only better, and the packing will hold some of that when it comes. I do not say I know this to be an improvement, but I certainly think so.

North Auburn, Me., Nov. 5, 1883.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

In reply to Mr. A. J. Fisher, on page 564, I will say that after considerable experimenting the past season, we prefer our sections $1\frac{1}{2}$ inches wide to be used without separators, especially with the smaller-sized sections. No doubt half size starters or pieces of foundation will guide them in sections as straightly as pieces of full-size, but no more so, if the full-size pieces are properly adjusted. A great reason for using full-size pieces in sections, is to prevent the building of drone comb there, in which the queen is very apt to lay, if we have none, or very little comb in the brood chamber, which is the case now with more progressive bee-keepers, who are using full sheets of worker foundation in all the brood frames. I do not think there is much, if any more danger of the queen breeding in thin than in thicker sections, as she deposits her eggs at or previous to that point in the growth of the comb, when it is $\frac{3}{8}$ thick. What prevents her from occupying it, is the tendency on the part of the bees to fill it with honey as fast as built.

Yes; we find the thinner combs built straighter.

Cellar Ventilation.

I intend to winter my bees in a room partitioned off in the cellar, and intend to have a $2\frac{1}{2}$ inch pipe to go through the floor and connect with the stove-pipe. Will Mr. Heddon please answer through the "What and How" department of the BEE JOURNAL if it would be better to have a branch from the main pipe in the room, and have the main pipe go within a foot of the floor, and the other near the ceiling of the bee room,

so as to warm the air from the bottom and top of the bee room?

Hamilton, Ont. A SUBSCRIBER.

ANSWER.—Your stove above your cellar will not "warm" the air in any part of your bee room at all. Should that word warm not be draw? Changing it thus, I would say that I would not use any branch to the main pipe; I would run the main pipe to the bottom of the cellar, resting it up on legs, 5 or 6 inches, and I would prefer a pipe 5 or 6 inches in diameter.

SELECTIONS FROM OUR LETTER BOX

Good Qualities of Cyprian Bees.

As they are often condemned for stinging so readily, I will enumerate their good qualities: 1. They never volunteer an attack on anything. You can pass the hive, and they may alight on you, but they do not sting. 2. They are superior honey-gatherers. 3. They winter better than any others. When at the St. Louis fair, all thought them "the coming bee." When they are pure, you can handle them with pleasure by using a little smoke. This is the second year that I have kept pure Cyprians, and I think them ahead of all others. I started the last season with 26 colonies—increased to 53, mostly by natural swarming. Though there was no fall honey, they go into winter quarters in good condition. On Oct. 7, two swarms of bees came to my apiary from a neighbor 4 miles away, who kept them on the old-fogy plan. I hived them and they are doing well. What caused them to swarm? Casey, Ill. D. R. ROSEBROUGH.

[They were evidently dissatisfied with their surroundings, and, being disgusted with their condition, they concluded to seek other quarters.—ED.]

Bees Buried in a Clamp.

My bees have done very well, this season. I have 33 colonies in fair condition. I am burying them in a clamp. W. W. TRUSSEL.
Colby, Mich., Nov. 12, 1883.

Wintering Bees in Northern Kentucky.

The way I winter my bees, here in northern Kentucky, has proved a perfect success every time, so far. I simply make a shed long enough to hold my bees, and about 6 feet wide, three sides sided up as tightly as possible, leaving the side facing the southeast open. I then place on the ground about 3 feet of straw, then set the bench on top of the straw, which will sink down about level with the top of the straw, in a short time; I then put on the hives, with the entrance facing the southeast. This may not do in a colder part of the country, but here in Kentucky it does

well, or at least it has done so with me. I have 3 colonies as good Italians as I can get; the rest in my apiary are hybrids; although I am partial to the Italians, I must confess that the hybrids are the best honey gatherers; at least, mine are.

ADRON B'HYMER.
Kenton Co., Ky., Nov. 11, 1883.

Special Premium.

Your correspondent H., in his report of the St. Joseph Inter-State Exposition, omitted to mention the special premium for the best 30 pounds of comb honey on exhibition (\$29.00), which was awarded to me. I think the report, as it stands, is hardly just to me. The entry upon which I took a second premium required quantity as well as quality.

J. B. STANCLIFT.
Brookfield, Mo., Nov. 7, 1883.

Too Large.

At our Fair a "Monarch" bee hive was exhibited, but it is not a practical hive at all. 1. It is too large to be carried around—and would require 2 men to move it at all. 2. It is too large for one colony to keep up the required heat. 3. A man should be made of iron to manage an apiary of such. 4. The brood-chamber is large enough for 2 colonies; it has apartments for extracted honey on top, and at one side of the brood-chamber it has 144 sections, quite enough for 2 hives. Beginners should be careful not to use such a hive.

W. R. STIRLING.
Fairfield, Ont., Nov. 12, 1883.

Lath Hives.

My bees are all packed in sawdust in hives, which neighbor Clow and I use; we make them of laths, and put 2 colonies in a hive. We use the Gallup frame, and can extend the hive, when the packing is removed from the sides, making room for 13 or 14 frames. When the honey season is over, we take out the side frames, and put in the division boards, which are made of laths, to make the hive porous; that leaves the hive 12x14 inches inside. I leave 9 frames for winter, and crowd the bees on to them. I then put some ½ inch strips on the top of the frames, and cover all with burlap, then put sawdust on the top of the whole hive, to the depth of about 3 inches. The hive is 2 feet high, to receive surplus boxes. The space is all open up to the roof, which is made of shingles, which makes a good roof. Bees did not do very well this season; we only had about half a crop. Two of my colonies gave 150 pounds of comb honey in one-pound sections; the others did not do so well. One of these queens was a cross between the Cyprian and Italian; the other a cross between the Cyprian and German or brown bee. They are both tolerably fiery. The one with the German blood makes the whitest combs; the other has the most delicate and docile bees. I have but 22 colonies. I might have had more if I had let them swarm. I use racks holding 30 pound boxes in each, which fills the top of the brood-

chamber. I have no trouble in knowing when sections are full, and no trouble to speak of in taking them off.

D. C. McLEOD.
Pana, Ill., Nov. 14, 1883.

Honey Crop, Red-Headed Drones, etc.

My bees are hybrids from Syrian, Italian and blacks. This year I commenced with 28 colonies; increased to 54, and extracted 2,800 pounds of honey. The least, from my poorest colony, being 30 pounds; and the most, from my best, a pure Syrian colony, was 160 pounds. This is the best I have ever done, with any kind of bees. The most serious drawback to the Syrians, is that it takes about 10 days before the young queen begins to lay. The bees go into the sections with a will. Syrian queens need 2 more brood frames than any others. I could have had 5,000 pounds, this summer, if I had extracted every 4 days; I only extracted 3 times in as many weeks. During the basswood bloom, I took 900 pounds in one day, just what the boxes held. I have 62 colonies in the cellar in good condition. I have sold my honey at home at an average of 11 cents per pound. I have a number of colonies which had red-headed drones. Where did they come from? I had 2 with white eyes. The queens are from a pure Syrian colony, and have half black and half red heads.

FAYETTE LEE.
Cokato, Minn., Nov. 7, 1883.

[Red-headed drones, as well as grey-headed ones, have been often mentioned. It is simply a freak of nature.—ED.]

The Independent.

The ablest religious and literary newspaper published. One-quarter to one-third larger, but the same price as its contemporaries.

It has twenty-two distinct departments, all good, many of them of superior excellence.

Its literary department, embracing reviews, criticisms and notices of all new books published, contains 10 or 12 columns weekly, and has no superior in journalism.

During the next few months THE INDEPENDENT will publish stories by William D. Howells, author of "Their Wedding Journey," "A Modern Instance," etc.; W. E. Norris, author of "Matrimony," "No New Thing," etc.; F. Marion Crawford, author of "Mr. Isaacs," "Dr. Claudius," etc.; J. S. of Dale, author of "Guernedale"; Edward Everett Hale, author of "Ten Times One is Ten," etc.; Julia Schayer, author of "Tiger Lily and Other Stories"; Rebecca Harding Davis, Sarah Orne Jewett, Fred. D. Story, Kate Upson Clarke, and others. Our readers who do not now subscribe for it should read the advertisement in another column, which gives subscription rates in full. Every one should at least send 30 cents for a month's "Trial Trip," and make its acquaintance. Address THE INDEPENDENT, New York City.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper, shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter, on your label, notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a statement of account every week.

Our New List of Premiums.

Getting up Clubs for 1884.

To increase the number of readers of the BEE JOURNAL, we believe, will aid progressive bee-culture and help to elevate the pursuit. We, therefore, offer the following premiums for getting up clubs:

While no subscription to the BEE JOURNAL will be taken for less than the regular advertised prices (viz.: Weekly, \$2.00; Monthly, \$1.00),—any one getting up a club of two copies, or more, may select from "OUR BOOK LIST" anything therein named, to the amount of 15 cents for every dollar *they send direct to this office*, to pay them for the trouble of getting up the club; and these books will be sent, postpaid, to any address desired.

For a club of 3 Weekly or 6 Monthly and \$6.00, we will make an *additional* present of a Pocket Dictionary, bound in cloth, containing 320 pages.

For a club of 5 Weekly or 10 Monthly, (or a mixed club of both,) with \$10, we will, in addition to the 15 per cent. present a copy of the AMERICAN "POPULAR" DICTIONARY, comprising every word in the English language that enters into speech or writing; it contains 32,000 words and phrases, 670 illustrations and 512 pages; it is nicely bound in cloth, and will be sent by mail, postpaid, to any address desired.

For a club of \$20, for 10 Weeklies, or an equivalent in Monthlies, we will present, besides the 15 per cent. in books, a tested Italian queen, by mail, postpaid.

Announcements for larger clubs will be made hereafter.

Subscriptions for two or more years for one person, will count the same as each year for a different person.

☞ To give away a copy of "Honey as Food and Medicine" to *every one who buys a package of honey*, will sell almost any quantity of it.

☞ Have you ever thought how much entertainment might be had at home evenings, if you could only find some way to use your chromo cards, photographs, scrap pictures, etc., in a magic lantern, instead of the old familiar stock of glass slides? It seems almost like wishing for the impossible, and yet a cheap instrument has been invented for the purpose, called the *Polyopticon*, and you can learn all about it by enquiring of the Murray Hill Publishing Co., 129 E. 28th St., New York City.

Hope for the Deaf.—In another column will be found an advertisement with the above head. We have seen the descriptive book coming from this house, and judge from the testimonials therein contained that it is a very successful device to restore hearing. The book is sent free. It will well repay a perusal. Send for it.

Bee Pasturage a Necessity.—We have issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for ten cents.

THE AMERICAN POPULAR DICTIONARY.

CONTAINING
EVERY USEFUL WORD IN THE ENGLISH LANGUAGE.

With its Correct Spelling, Proper Pronunciation, and True Meaning.

ALSO, A VAST AMOUNT OF
ABSOLUTELY NECESSARY INFORMATION
UPON
Science, Mythology, Biography, American History, Constitutions, Laws, Growth of Cities, Colleges, Army and Navy, Rate of Mortality, Land Titles, Insolvent and Assignment Laws, Debts, Rates of Interest, and other Useful Knowledge.
BEING A PERFECT LIBRARY OF REFERENCE
IN ONE HANDY VOLUME.
512 pages; Cloth; Gilt; Illustrated.

This Dictionary is our Premium for a Club of 5 subscribers to the Weekly (or its equivalent to the Monthly), in addition to other Books selected from our Catalogue to the amount of \$1.50; all by mail, postpaid.

A POCKET DICTIONARY

Containing 320 pages, and over
25,000 Words, Rightly and Plainly Defined.

To make the pronunciation easily understood every word is phonetically re-spelled, and the syllables and accents made perfectly plain, so that no one who consults this book can miss the proper word to use, and giving it proper pronunciation.

☞ This Dictionary is our Premium for a Club of 3 subscribers to the Weekly (or its equivalent to the Monthly), in addition to other Books selected from our Catalogue to the amount of \$1.00; all by mail, postpaid.

To Every Subscriber

TO THE PEOPLE'S

FIRESIDE JOURNAL

Watch

Free!

The PEOPLE'S FIRESIDE JOURNAL of NEW YORK now in its SIXTH YEAR, is determined to lead the race in premiums, as it always has done, by giving the best paper for the money. In order to get the paper into every home in the land, we give an inducement which cannot fail to accomplish our object. We have decided to make the following princely and magnificent offer to each and every reader of this paper. It is the common practice of the gold and silver refiners of England and Switzerland to purchase from the pawnbrokers of their respective countries all the gold and silver watches which have been unredeemed, simply for the sake of the gold and silver cases. The works are then sold to a celebrated watch firm who have made a specialty of this business. The firm places the works in the hands of skillful workmen, who set to work and put them in as good condition as possible. These works embrace every variety of movement, some of them being very fine and perfect time keepers, all handsomely cased. WE HAVE NOT PURCHASED THE ENTIRE STOCK (25,000) of a bankrupt concern of the above described watches at less than the first cost of the raw material.

ON RECEIPT of \$2.50 we will send THE PEOPLE'S FIRESIDE JOURNAL for one year, and one of these watches prepaid to any address in the United States or Canada. WATCHES AND PAPER MAILED SAME DAY AS ORDER IS RECEIVED. These watches are not sun dials or solar watches but genuine, good time-keeping watches, and they will only be supplied to subscribers to the FIRESIDE JOURNAL. Only ONE WATCH TO EACH SUBSCRIBER, and you must cut out this advertisement and send it to us as a voucher that you are entitled to the same. If you send 50 cents extra, we will send you a handsome chain and charm. We have THOUSANDS of TESTIMONIALS, but have no space to print them. Our reliability is undoubted, as the paper has been well and favorably known for six years. If you are not ENTIRELY SATISFIED when you get the paper and watch, we will RETURN YOU THE MONEY, or you can send 50 cents, and have the balance collected. C. O. D. if you choose. If you will get 15 subscribers a \$2.00 each, all of whom will get the above watch, we will in addition send you a HANDSOME GOLD WATCH for your trouble, either for lady or gent.

Our profit in this transaction is not going to come from this trade, as we lose money on it; but when we get subscribers to our paper they like it so well they will always take it. Send postal note. Address,

PEOPLE'S FIRESIDE JOURNAL, New York

No. 48.

THE AMERICAN
BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Call Things by their Right Names.

For a long time we have contemplated writing an article on the above subject, but deferred it, because of the labor necessary to cover the entire ground. Mr. F. L. Dougherty lately gave the following, on this subject, in the *Indiana Farmer*, which we quote as an introduction to what we wish to say. He says:

"Do not call a frame, a 'rack' or a 'sash'; call it a frame. When filled with comb, it may be called a comb. A rack is a form which rests on the hive, to hold sections. Sections are for surplus comb honey. A hive is a box or other receptacle for bees. A hive full of bees is a colony. When a colony is on the wing or clustered, it is a swarm."

That is the whole thing in a nutshell; but to reform this extensive abuse of language, we think will require more than a passing remark. The nomenclature of bee-keeping is sadly out of harmony, and it needs a thorough over-hauling to induce correspondents to use proper terms, when writing on bee topics. Quite often it is very difficult to determine what idea is meant to be conveyed, because of this habit of calling things by their *wrong* names.

Some writer astonishes us with the remark that he "wintered" his "stands in the cellar," and that "they came out in bad shape." The "stands" are the supports upon which the hives rest, and as they may be left on the places where the hives stood in the summer, we cannot think that the writer meant that they were taken into the cellar at all, so we have to *imagine* that he meant that his colonies of bees were "wintered in the cellar," though he does not say so!

He also says that his "stands" "came out in *bad shape*!" What! Did the "stands" change their shape? If the pieces of wood were nailed in a rectangular form, did they change, of their own accord, to a square "shape?" or, What was the matter?

Again, if we *suppose* that he meant the "colonies of bees" when he said "stands," we are "just as much at sea" to determine what is meant by their "coming out in bad shape!" Did his bees change their *shape*? Were they bees, when put in the cellar, and were they of the shape of mice, rabbits or birds, when taken out? As this cannot be what was meant, we are called upon again to *imagine* that he was speaking about their *condition*. Now, all this confusion would have been averted, if he had simply said that his bees were wintered in the cellar, and when taken out were weak, diseased, or dead, as the case might have been. Such language would have conveyed an intelligent idea, but to say that his "stands" came out of the cellar in *bad shape*, conveys no intelligent idea at all!

Another correspondent assures us that "Mr. — wintered in his cellar." Did he? Poor fellow; what a pity that he did not have a dwelling house over that cellar in which to live during the winter! We admit that there are thousands in crowded cities who live, both in summer and winter, in cellars, but, alas, "their days are few and full of disease!" But our correspondent evidently did not mean to convey that idea at all—he only *meant* to say that Mr. — put *his bees* in the cellar to winter *them*! Then, why did he not say so, and convey an intelligent idea?

Another writer astonished us with the assertion that four of his "hives ran away to the woods!" It would have been worth a trip of several miles to see hives running over fields, fences, and perhaps rivers "to the woods!" But he evidently meant to say that four swarms came out of the

hives, and *flow* away to the woods. That robs the matter of all obscurity!

Scores of similar nonsensical expressions are used to confuse the reader. We have, for years, studiously avoided using many of such expressions in the *BEE JOURNAL*, by correcting all manuscripts before giving them into the hands of the printers, and we already notice a very marked improvement among our correspondents, and to encourage further reform, we invite the attention of the reader to the following explanations of terms used in the pursuit of bee-keeping:

Abnormal Swarm.—Bees leaving a hive, from some unnatural cause.

A Colony of Bees.—An organized body of bees; and, when complete, having a queen, a few hundreds of drones, and many thousands of worker bees. Improperly called a swarm, stock, stand, hive, gum, skep, etc.

A Swarm of Bees.—Bees issuing from the parent colony for the purpose of increase.

After-Swarms.—Those issuing subsequent to the first swarm.

Alighting Board.—A board at the entrance, for the bees to alight on.

Apiarist.—An expert bee-keeper.

Apiary.—A place where bees are kept.

Apiary Register.—A book in which to keep a record of both queens and colonies.

Apiculture.—The pursuit of bee-keeping.

Balling a Queen.—A cluster of bees around a strange queen, trying to sting her.

Bee Bread.—Pollen.

Bee Diarrhœa.—A disease of bees, improperly called dysentery.

Bee Gum.—Part of a log which wild bees have inhabited.

Bee Hive.—A box, with suitable fittings, to hold a colony of bees. Improperly called a gum, skep, etc.

Bee House.—A house to hold several colonies of bees.

Bee Moth.—A miller which preys upon the combs.

- Bee Pasturage.**—Honey-producing trees, plants or shrubs; improperly called artificial pasturage.
- Beeswax.**—A substance made by bees for building comb.
- Broad Frame.**—A wide frame for holding sections.
- Brood.**—Larvæ in all stages.
- Brood Combs.**—Combs used for breeding purposes.
- Cases.**—Wide frames to hold sections for surplus honey.
- Cells.**—Hexagonal birth-place of bees and depositories for honey.
- Chaff Hives.**—Double-walled boxes, filled in with chaff, for bees, both in summer and winter.
- Cluster of Bees.**—A festoon of bees clinging to one another.
- Comb Basket.**—A basket to hold combs in a honey extractor.
- Comb Foundation.**—Sheets of wax on which the base of cells have been imprinted by a machine, mill or press. Improperly called artificial comb.
- Comb Guide.**—Small pieces of comb foundation, to guide the bees in building combs in frames or sections.
- Comb Honey.**—Honey in the comb.
- Cushion.**—A bag filled with chaff or something porous, to be placed over or at the sides of the frames in cold weather.
- Cyprian Bees.**—Bees from the Island of Cyprus.
- Dividing.**—A method of increase by dividing two or more colonies.
- Division Board.**—Used for contracting the brood-chamber of the hive.
- Drones.**—Male bees.
- Driving Bees.**—Drumming on the outside of a box hive, to drive the bees up into an empty box on top.
- Entrance.**—A passage way for the bees to enter the hive.
- Entrance Blocks.**—Used for contracting the entrance.
- Extracted Honey.**—Honey taken from the combs by centrifugal force. Improperly called strained honey, which was obtained by mashing up the combs and straining through cloth.
- Granulated Honey.**—Honey formed into grains. Improperly called candied and crystalized honey.
- Hatching Brood.**—That just emerging from the cells.
- Honey.**—Nectar gathered by bees from flowers.
- Honey Board.**—A board or slats used over the frames, to support the surplus receptacles.
- Honey Extractor.**—For extracting honey from the combs by centrifugal force.
- Honey Gate.**—A faucet for drawing honey from the extractor.
- Honey House.**—A place for storing and extracting honey, etc.
- Honey Knife.**—Used for uncapping the cells, before extracting.
- House Apiary.**—A building having double-walls, in which to keep several colonies of bees.
- Hybrids.**—A cross between two species of bees.
- Italian Bees.**—Bees from Italy. Sometimes called Ligurian, because they were imported from Liguria.
- Introducing Queens.**—Inserting a strange queen in a colony.
- Lamp Nursery.**—Used in rearing queens.
- Larva and Pupa.** (plural, Larvæ and Pupæ).—Unsealed brood. The first stage is the egg; the second is the larva; the third, the pupa; the fourth, the imago, the last stage of insect life.
- Laying Workers.**—Those workers that lay eggs, which produce drones.—Improperly called fertile workers.
- Mandibles.**—The bees' jaws.
- Manipulation.**—The handling of bees.
- Metal Rabbits.**—Strips of folded tin, on which the frames rest.
- Movable Frames.**—Frames enclosing the breeding combs, by which they can be handled. Improperly called sash, slats, etc.
- Natural Swarm.**—One that issues naturally.
- Nucleus.** (plural, Nuclei).—The foundation for a colony, with a queen or eggs from which to rear one, and one or more frames of bees and brood.
- Nursing Bees.**—Young bees whose duty it is to care for the brood.
- Observation Hive.**—Having a side or sides of glass, for observing the work of bees.
- Overstocking.**—When there are more bees in a locality than there is pasturage for their support.
- Piping of the Queen.**—Notes of anger produced by a queen, who is prevented from killing her rivals, by the bees who intend to swarm.
- Pollen.**—The farina of flowers, when mixed with honey, the food of young bees.
- Pollen Baskets.**—A cavity on the hind legs of the workers in which to carry pollen.
- Propolis.**—Bee glue, a resinous substance gathered from trees, etc., and used by the bees in cementing and filling up cracks, etc., in hives.
- Queen.**—The mother of the colony.
- Queen Cage.**—A cage used in shipping or introducing queens.
- Queen Cells.**—Large cells in which queens are reared.
- Queenlessness.**—Colonies having no queen.
- Queen Rearing.**—Rearing of queens. Improperly called raising queens.
- Quilt.**—A cloth covering for frames.
- Rendering Wax.**—Melting combs, and clarifying the wax.
- Ripe Honey.**—Honey that is ready to be capped.
- Robbing.**—Bees stealing stores from other colonies.
- Royal Jelly.**—Food of queen larvæ.
- Sections.**—Small receptacles for surplus honey in the comb.
- Separators.**—A strip of tin or wood, placed between sections, to insure straight combs.
- Spring Dwindling.**—Decimation of a colony of bees in spring.
- Starters.**—Small pieces of foundation or comb fastened to the top of sections, to induce the bees to work in them.
- Sting.**—The bees' weapon of defense. Drones have none.
- Super.**—A rack to hold sections on the hive.
- Syrian Bees.**—Those from Syria or Palestine. Improperly called "Holy Lands."
- Tested Queen.**—One whose progeny, when tested, is found to be pure.
- Transferring.**—A transfer of bees and combs from one hive to another.
- Unripe or Green Honey.**—Honey extracted before being capped, and not evaporated or ripened.
- Untested Queens.**—Those not tested for purity. Sometimes improperly called "dollar queens."
- Virgin Queens.**—Queens which have not been fertilized.
- Warranted Queens.**—Not tested, but guaranteed to be purely fertilized.
- Wax Extractor.**—For rendering wax, by the aid of steam.
- Wedding Flight.**—An excursion of a virgin queen to meet a drone.
- Wide Frames.**—Frames 2 inches wide, to hold sections at the side of the brood-chamber, or in the second story.
- Wild Bees.**—Those in the woods or rocks, etc.
- Wind Breaks.**—Hedges or fences to break the force of the wind upon the apiary.
- Worker Eggs.**—Eggs laid by a fertile queen, which may, at the pleasure of the bees, produce either workers or queens.
- Workers.**—Undeveloped females, who do the work of the hives. They are improperly called "neuters."

We hope that all who write for publication, or talk at Conventions, will carefully consider this matter, and, in future, *call things by their right names*. It will save much embarrassment by the "confusion of ideas," as well as the annoyance of being misunderstood, when confounding terms. "A word to the wise is sufficient."

Bees in Oregon.

The Northwestern *Farmer & Dairyman*, of Portland, Oregon, gives the following historic account of the introduction of bees into Oregon:

Strange as it may seem, there were no wild bees to be found in Oregon, and not even on the Pacific coast prior to the introduction of tame ones here. On careful inquiry, we learn from some of the early pioneers that a man named Buck, and at latest accounts still living in California, made the first successful importation of bees into this country, landing with several colonies in Portland during the summer of 1853. These bees were principally purchased at the apiary of John I. Wood, of Sullivan County, New York. Mr. Jas. Terwilliger, of South Portland, had the good fortune to receive the first colony sold by Mr. Buck in Oregon, paying \$125 therefor. Mr. Thos. Stephens bought the second one sold, paying the same price. These bees were brought to this country by way of the Isthmus route and San Francisco, where, after a stoppage of some considerable time, they were re-shipped to their destination—Oregon.

Mr. Gideon Tibbetts, of East Portland, is authority for the statement that his son-in-law, Dr. D. S. Baker, now of Walla Walla, purchased a colony of bees in New York or Pennsylvania, about the year 1852, and started with them for Oregon, coming by way of Panama. On reaching San Francisco, the bees were found alive and well. They were then re-shipped to Portland, and came on the same steamer in which Dr. Baker was himself a passenger. While on the way hither from the Golden Gate, the bees were robbed of their honey by thieving sailors or passengers on board, and, on the arrival of the vessel at this port, were all found dead, having perished through suffocation at the time of the robbery, or succumbed to hunger afterwards.

In 1858, Mr. Chas. Knowles brought 30 colonies of bees from California, on the old steamer Columbia, and located with them on the Tualatin Plains. In a season or two his colonies increased altogether to about 100, which he sold for \$125 each, and afterwards moved to the lower Columbia river and made a fresh start in the business.

When bees were first introduced into Oregon, they were objects of much curiosity to the Indians, and to many of the native young people among the whites, and there were many persons who traveled long distances to see them at work.

From a small beginning, a few years ago, bee-culture has made great developments in this Northwest land, and we hope, at no distant day, to see it made one of the chief industries of this State and Washington. To those of our citizens who have given the careful and intelligent attention demanded, bee-culture has always returned handsome profits.

Be Courteous, even if you Cannot Approve.

We are having considerable discussion in the BEE JOURNAL now. This is all right, if it is written kindly, and without sarcasm. Discussion is the royal road to progress and improvement, and should at all times be encouraged. But unkind personalities are never welcome, and only show a lack of argument by the person using them. We are more than pleased with many controversial articles contained in several late numbers, and hope the same kind words, but strong arguments will characterize those that are to follow. One of our correspondents, in a private letter, gives his views of the subject in the following language, which we heartily endorse:

"I trust that my opponents, if I have any, will try and be courteous, as while I am ready at any time to give blow for blow, and sarcasm for sarcasm, I much dislike so to do, for the reason, that no good comes from it. It may please some readers to find articles, from time to time, where some one vents spleen, but the majority of bee-keepers, if 'wedded to their idols,' still are gentlemen, and dislike fights where paper bullets are used."

Owing to the death of our Secretary, Mr. T. Brookins, please announce in the BEE JOURNAL that the annual meeting of the Champlain Valley Bee-Keepers' Association, will meet in the parlors of the Addison House, Middleburg, Vt., the second Thursday in January, 1884.

J. E. CRANE, Pres.

The editors of the *American Agriculturist* claim that the November number is not only superior to any other issue of that periodical issued during its 43 years of existence, but is far superior to any number of any similar journal in the world. They certainly have presented an amount and variety of matter which, considering the price of the periodical, is remarkable.

Do not let your numbers of the BEE JOURNAL for 1883 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

Honey and Beeswax Market

OFFICE OF AMERICAN BEE JOURNAL.
Monday, 10 a. m., Nov. 25, 1883.

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The market is slow; arrivals exceed the demand which, however, has improved some. There is a better demand for comb honey, and supplies are short, which, no doubt, is temporary, as usual. Last year at about this time, comb honey was at its highest, when our sanguine friends very naturally held on, expecting more. However, large supplies commenced to arrive, and prices kept coming down steadily. Bee-keepers in general bent their energies on the production of extracted honey last season, more than ever before. We had a large crop, and extracted has been dull so far, not only because of the large supply, but because manufacturers complain of dullness in their business. Consequently, we have reason to believe that the present slow market is temporary.

The present state of the honey market gives our bee-keeping friends another chance for a disappointment, to-wit: That of over-production of comb honey another season. This is merely an idea of my own, and our friends may take it for what it is worth.

Extracted honey brings 7@9c. on arrival. Best comb honey, 16@17c.

BEESWAX—Is of ready sale at 28@30 on arrival.

CHAS. F. MUTH.

NEW YORK.

HONEY—White clover and basswood in 1 and 2 lb. sections, 17@21c. Dark and second quality, 14@15c.; extracted white clover in kegs and barrels, 9@10c.; dark, 8c.

BEESWAX—Prime yellow, 27@29c.

H. K. & F. B. THURBER & Co.

CHICAGO.

HONEY—The market remains without change from that of last week. Dealers and retailers buy only enough to supply the demand for present use. It is impossible to place lots, or entire shipments, owing to the reluctance of dealers to buy in advance of immediate wants. Prices obtained for white comb in 1 lb. sections, 18@20c.; 1½ lb. and 2 lb., 15@18c. according to beauty of assay. Extracted honey, 8@10c. per lb., according to color, body and flavor.

BEESWAX—Yellow, 33c.; medium, 28@30c.

R. A. BURNETT, 161 South Water St.

SAN FRANCISCO.

HONEY—Market is well stocked with ordinary qualities. Inquiry for the same is not active. For fancy comb it is an easy matter to secure custom. White to extra white comb, 16@18c.; dark to good, 12@14c.; extracted, choice to extra white, 7@8½c.; dark and candied, 6½@7c.

BEESWAX—Wholesale, 27@28c.

STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Choice comb in light supply—fair demand and firm, at 15@17c.; dark, brood and partly hand, dull at less. Strained and extracted steady at 6½@7½c.; choice in fancy packages more.

BEESWAX—Better, at 28c. for prime.

W. T. ANDERSON & Co., 104 N. 3d Street.

CLEVELAND.

HONEY—Choice honey is in excellent demand now. Every lot received thus far in good order, has been sold on arrival; best 1 lb. sections bringing 18c. quickly, occasionally 19c.; 2 lb., 17c. with an occasional sale at 18. Second quality and broken lots are very hard to sell. Extracted honey not in demand.

BEESWAX—28c.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—Our market is very quiet on honey. We quote 16@18c. for best 2 lb. sections—18@20c. for best white 1 lb., and 10c. for extracted.

BEESWAX—We have none to quote.

BLAKE & RIPLEY, 57 Chatham Street.

KANSAS CITY, MO.

HONEY—Receipts of comb honey has been more liberal for the past week, but the demand still keeps everything that is of fair quality well cleaned up. Choice 1 and 2 lb. sections are taken on arrival at 18c.; larger sections and dark honey 16@17c. Sales of extracted for the past week about 4,000 lbs., mostly at 8 cts. The feeling for extracted is a little better, and I look for a firmer market.

JEROME TWICHELL, 336 Delaware Street.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

CORRESPONDENCE

For the American Bee Journal.

Pollen—Now for the Facts.

G. M. DOOLITTLE.

For the past three years much has been said by the press and otherwise about pollen as being the agent of, if not the direct cause of our wintering troubles with bees. Most writers on the subject claiming that the eating of pollen was the cause of dysentery, for in order to become the cause, or an agent of, the bee must eat the pollen, as all will admit. In all of these discussions (which I have watched very closely) about the matter, I have failed to see any proof given that old bees *do* eat pollen.

After carefully reading all Mr. Heddon (who has been the main agitator of this question) has written on the subject, I fail to find anything which shows why he believes the theory he advocates, unless it be on page 283 of the BEE JOURNAL for 1881, when he says, "I have not found a dead colony, where there was not plenty of bee-bread, showing signs of late work with it, or brood in all stages, and generally both, but nearly always brood." But it will be noticed he does not tell us what those signs were, or whether he saw the signs in the absence of brood.

On page 560, present volume of the BEE JOURNAL, Mr. Kohnke is very positive about the matter, and says regarding dysentery: "If Mr. Heddon had omitted one word in his reply to Rev. L. L. Langstroth when he says, 'But they are sometimes compelled to eat it' (pollen), he would have given the sole and only reason for bees dying with it. Drop the word 'sometimes,' and you have the whole thing in a nut shell." Here, again, the reader will notice that no proof is given to support the assertion.

Since Mr. Heddon's article appeared on page 283 of the BEE JOURNAL for 1881, I have tried several experiments to make old bees eat pollen when there was no brood in the hive, all of which have resulted in the starvation of the bees without a bit of pollen being consumed, as far as I could see. The first experiment I tried was this: I had a colony which had a queen which produced bees of a bad disposition, so much so that I did not care if they died. From these I took away all their honey as soon as they had ceased brood rearing (which was about Oct. 12), and substituted frames of pollen with little or no honey in them. The result was that as soon as they had consumed all the honey they had in their sacks, when I shook them from their combs of honey, and the little there was in the combs given them, they died. The pollen was carefully marked, and the combs examined every other day, as I wished to ascertain the facts in the case. As long as a cell containing a little honey

could be seen, the bees were as active and lively as any bees, but soon after there was no honey to be seen, the bees became drowsy except in the centre of the cluster. In a few days those on the outside were apparently dead, having most of them dropped to the bottom board, or crawled into an empty cell where such could be found among the cells of pollen, while those in the centre of the cluster were sleepy as were those outside a few days previous. At this time the queen was still quite active with, perhaps, a dozen bees near her, but the most of the bees could hardly cling to the combs, while every available cell was filled with bees, too drowsy to back out upon being touched.

The next examination found them all apparently dead, but I succeeded in bringing a few to life by warming them and giving some honey as soon as they would take it. During all this process I could not discover that a particle of pollen was eaten, although I watched very closely. Many interesting facts were brought out, however, such as which bees succumbed first, that the queen was held precious to the last, and that bees could be brought to life after apparently dead, etc., but it would be out of place to dwell on them here.

Other experiments were tried "not unto death," but all to no avail as regards forcing the bees to eat pollen without the presence of brood. This fall I experimented, to see if it made any difference whether the pollen was covered with honey or not, giving a colony frames having a little patch of pollen covered with honey, all the rest of the honey being extracted from them. Although I held the bees to the experiment till I starved $\frac{3}{4}$ of the colony, still none of the pollen was eaten. In no case did I ever know old bees to eat pollen except where brood was being reared. If pollen is used while brood is being reared, and at no other time, then the brood becomes the prime cause of dysentery (if dysentery is thus produced) and the pollen secondary. That old bees are kept from starving during times of scarcity in spring and summer by eating pollen when there is plenty of brood in the hive, I think I have abundant proof of, but in this case the old bees do not partake of the pollen, only as it is partially digested in the stomach of the nurse bees and formed into chyme, when it is fed to the old or field bees the same as it is fed to the larvae.

By placing frames of pollen in hives containing no honey at such times, I have had the pollen rapidly consumed, and the bees kept lively, while those beside of them would eat up all their brood and starve as soon as the pollen was gone, unless fed. It may be possible that as soon as brood-rearing begins in the hive in the winter, that the old bees are fed pollen in this way, with plenty of honey in the hive, but I have my doubts about it. But if we admit this to be a fact, and that dysentery can be thus produced, then, as I said before, pollen can become only secondary as to producing dysentery.

From all the facts brought out by my experiments, I am convinced that pollen eating is not the cause of dysentery, and here venture the assertion that old bees will not eat pollen except as there is brood in the hive, and shall hold to it until it can be proven that they do.

Now, for the proof, gentlemen, and if you cannot furnish it, there is no need of dwelling upon the subject. We do not want any theories, or any guesses about it. Simply tell us just how you know that old bees eat pollen when the hives contain no brood, and if you prove they do, tell us also how you know that by eating it, dysentery is produced. I wish to here thank Mr. Cornell for his very clear and able article on page 557. He there gives us facts, which are of far greater import to the bee fraternity than a multitude of well-spun theories.

Borodino, N. Y., Nov. 13, 1883.

For the American Bee Journal.

Packing Honey for Shipment.

JEROME TWITCHELL.

I have a great many letters from all parts of the country asking how to pack honey for shipment, and for the benefit of all, I would like to make the following suggestions through the BEE JOURNAL:

All honey-producers will, of course, know that in packing the sections in the case, they must be so arranged that the combs will not touch each other, nor touch the sides of the case, and that they must be wedged in, so that they are absolutely immovable by the ordinary jar of handling the cases.

I would recommend always the use of the paper pan in the bottom of the case (heavy manilla paper folded at the corners in the form of a pan). It catches all drippings, and preserves the cleanliness of the case. The cases should be of clean new lumber, well fastened together with a panel of glass in one side any how, or even in two sides would be all the better, the glass serves the double purpose of revealing the contents to the handlers of it on the railroads, thereby making them more careful, and also affording the retail merchant a neat and convenient package from which to sell the honey.

Next, as to the size and shape of the cases. These should be as nearly uniform among all packers as possible, and I would suggest as follows, viz.: One-pound sections put 4 lengthwise and 6 across in a one-story case, or double in a two-story, making say about 20 pounds in one and 40 in the other. Two-pound sections, put 3 lengthwise and 4 across, making either one or two stories, and about 20 and 40 pounds in a case.

Larger sections than 20 pounds I do not recommend at all; so I have nothing to say about size of cases for them. Secure the lids with small nails, and not too many. There should always be hand-holds in the ends of the cases to insure the careful handling of them. Mark the weights on the end of

case; never on top, as they become blurred. The net weights are not essential, but the weights of the cases or tare must always be plainly given.

In marking for shipping use a very small stencil or card. If the above suggestions are adopted, comb honey may be shipped any reasonable distance by freight with perfect safety, and will bring better prices and quicker returns than the usual slipshod cases in all sizes and shapes.

Kansas City, Mo., Nov. 17, 1883.

For the American Bee Journal.

Marshall County, Iowa, Convention.

The Marshall County Bee-Keepers' Association met at the Court House in Marshalltown, Iowa, Oct. 6. The Vice-President, G. W. Keeler, in the Chair. The minutes of the previous meeting were read and approved. Mr. C. A. Hasken and Mr. M. M. Fuller were received as members of the society.

The subject for discussion, "Fall and Winter Care," was then taken up.

Mr. Keeler stated that his bees are wintered in a cellar, but he made no fall preparation for them, more than to put them in when it turns cold. He puts one above another. So far he was very successful in wintering.

Mr. Hosken winters his bees in the cellar, and preferred it to out-door wintering.

J. W. Sanders, being called for, said that we should see that all were made ready for the winter, in the latter part of the honey season. This is done by seeing that all have plenty of young brood, late in the season, so as to go into winter with plenty of young bees. This can be done by placing empty combs in the centre, if the queen lacks room, owing to an overflow of honey, or by feeding, if there is a lack of honey in the fields. He thought that many colonies of bees were lost in the latter part of the winter and early in the spring for the want of plenty of young bees late in the season. For the life of a bee is short when on the wing, and if it has spent one-half or two-thirds of its life in the field, it will naturally die before another season comes in. Therefore, he advised to have plenty of young bees to take the place of the old, to prevent what is called "spring dwindling." Fix all up for winter after the honey season is over by contracting the size of the hive, with division-boards, so that only enough combs remain to be occupied by the bees. This will make less space for them to keep warm. I prefer two boards, one on each side. The extra combs can be placed away for use in the spring, as needed. If any colonies are short of stores, add to them by taking from those that has plenty and some to spare. He prefers a good quilt to a honey board, for a quilt allows the escape of the moisture and retains the heat of the bees. He had seen hives with honey boards damp and moldy, while in others, close by them, the quilts were dry, and the bees in prime condition. He made quilts from old worn-out clothing or carpets, or anything that will

make a good warm quilt, the size of a honey-board. After all are thus prepared, let them remain until winter begins, then put them in the cellar, leaving the entrances open full width; place them a foot or more above the bottom of the cellar, with the back end of the hive, 2 or 3 inches higher than the front. Keep the cellar above the freezing point, say about 40° to 45° Fahr., and give them plenty of fresh air.

The following report was then made: Mr. Hasken had 15 colonies in the fall of 1882, 13 in the spring of 1883, and has 32 now (sold 2), and 300 lbs. of surplus comb honey; Mr. Fuller had 5 colonies in the fall of 1882, 4 in the spring of 1883, 12 now, and 100 lbs. of surplus comb honey; Mr. Keeler had 42 colonies in the fall of 1882, 37 in the spring of 1883, 62 now, 838 lbs. of surplus comb honey and 2,880 lbs. of extracted; Mr. Sanders had 11 colonies in the fall of 1882, 11 in the spring of 1883, 25 now, 100 lbs. of surplus comb honey, and 350 lbs. of extracted; Mr. Brown had 2 colonies in the spring of 1883, and has 10 now, and 100 lbs. of surplus comb honey.

The subject for discussion at the next meeting, was "Promotion of Bee-Keeping."

The Secretary stated that the President of the Marshall County Agricultural Society requested all parties interested in bee-culture to meet with the Society at their January meeting, and assist in making out a programme for apiculture for the Fair of 1884.

The meeting then adjourned until the first Saturday in January, 1884, at the Court House in Marshalltown.

Conditions of Wintering.

J. E. FOND, JR.

The question of frames is one that excites the ire, or arouses the sensibilities of many to such an extent that I propose to avoid it entirely in this article, and confine myself wholly to discussing the general conditions in which a colony must be placed in order to most safely withstand the inclemencies of a northern winter. In the first place I shall assume (and I confidently assume without fear of opposition) that the nearer our bees can be kept to a state of absolute quiet, the more successfully will they be enabled to withstand, not only excessive cold but sudden changes of temperature, both from warm to cold, and *vice versa*.

To attain this state or condition of things, has been the aim and object of scientific apiarists for many years, and in their efforts in this direction, many experiments have been tried, with more or less success, but in none of which have such positive results been achieved, as to absolutely warrant any one in asserting that an absolutely correct method has as yet been discovered. In theorizing on the subject, the various questions of ventilation, moisture, excess of heat,

or want thereof, and various others considered of more or less importance have been discussed, but without as yet deciding anything satisfactorily, at least, the discussion still continues, and the experiments show that with all these points well fortified against, and also without any regard to any of them, bees live in some apiaries and die in others, no matter how much or how little care is taken in their protection. That this is so, proves conclusively that there is an error somewhere in our calculations, and that as yet we have not hit upon the right idea. I may be as wild in my opinions as any one, yet when I find that no matter what the conditions are, some apiaries are saved and some lost. I am emboldened to give my views publicly, and if nothing more comes of it, than to start discussions and experiments upon a new track, I shall have accomplished some little good, perhaps.

I am of the opinion that in our efforts so far, we have been laboring under the idea that bees need as much oxygen for their support, as we do ourselves, and our lack of success is caused by the incorrectness of that idea. As I stated in beginning, I believe that when we so prepare our bees that they will remain in a passive state, a state of nearly absolute quiet, an almost-dormant state, during the whole winter. No matter what changes of temperature may take place, then and then only shall we overcome the chief obstacle that exists to successful wintering. The fact that a hive of bees completely submerged under a snow-bank, during a long and changeable winter, will come out all right in the spring, is one strong proof in this direction.

This, I believe, is owing to the evenness of temperature which necessarily prevails where the colony is completely submerged in so had a conductor of heat as a snow-bank certainly is. No heat can get in, and none can get out; but it is not owing to this alone, but to the fact that excess of oxygen is kept out also. Snow is sufficiently porous to admit of the passage of sufficient air to enable one to live, still it will not allow of any excess of air to pass through it.

Excess of oxygen will, as a matter of course, excite human life, why not our bees? Any exciting cause produces a bad effect on our bees, by starting them up from that state of quiet so absolutely necessary for their preservation, at a time when they cannot fly freely from the hive. Oxygen must be an exciting cause to our bees as well as to ourselves; now is it not a logical deduction, and one that is presumably correct, that if we contract the entrances to our hives, so as to give our bees the least possible quantity of oxygen necessary for their support, we shall aid more largely in keeping them quiet, than by giving them a larger, and as some advise, as large an entrance as the width of the hive will allow? I ask the question in all honesty and sincerity, and desire an equally honest and sincere answer.

Foxboro, Mass., Nov. 19, 1883.

For the American Bee Journal.

Ohio State Convention.

The Ohio bee-keepers will hold their annual convention in Columbus, O., Jan. 14, 15 and 16, 1884. All interested in bee-culture are invited. The following subjects will be discussed: "How to winter bees successfully." "Are the new races of bees a success?" "What can we do to prevent adulteration of honey?" "How to create a home market for honey." "How many colonies can be kept in one locality?" "Can we do without separators?" "Which are best, deep or shallow frames?" "What shall we do with second swarms?" "How many brood frames are necessary in a hive?" "Which is the most salable section, one-half, one or two pounds?" "Is it advisable for all bee-keepers to adopt a standard size of frame?" "What is the most desirable width of sections?"

The above questions will be discussed by eminent men, such as Rev. L. L. Langstroth, Dr. Besse, S. D. Riegel and others, and in addition to the above, Prof. Lizenby, of the Ohio University, will deliver a lecture on "Honey-producing plants;" also Mrs. Jennie Culp will read an essay.

C. M. KINGSBURY, Sec.

Hamilton, Ont., Convention.

The bee-keepers of Hamilton district met in Convention at the Dominion Hotel, on Saturday, Nov. 10.

Officers elected for the ensuing year: W. J. Whitefield, Dundas, President; R. L. Patterson, Lynden, Vice-President; A. Robertson, Carlisle, Secretary-Treasurer.

The discussion on the best means of wintering bees on summer stands, was well sustained. The plan received with most favor was to permit free circulation of air beneath the hives, provided the tops of the hives are air-tight.

A question was raised as to the best food for bees at the present time, when the apiary held insufficient stores. In reply, it was suggested to feed comb filled with honey, and if without that, to suspend frames in the hives filled with sugar candy.

W. J. Whitefield offered a prize of one colony of bees for the best means of wintering bees. The conditions of the competition are: Entrance of 50 cents, to be applied to a second and third prize; colonies to be entered at date; prize to be given to the one having the largest percentage of numbers entered in best working order, May 27, 1884. The prize winners will be expected to make a statement in writing, for publication, to the judges of the mode of packing, character of hive, size of frame, winter and spring management. The parties getting the bees to furnish Mr. Whitefield with hives not later than June 10, 1884, and to remove them when notified. Competition confined to Wentworth county. Messrs. Whitefield, Patterson and Knowles were appointed a committee to meet the directors

of the Central Fair to arrange prize list, etc., for next year.

A committee was appointed to arrange for matters for discussion at the next meeting.

The Convention adjourned to meet again, April 12, 1884.

Wintering Bees on Summer Stands.

J. F. LATHAM.

Wintering! yes; that is what we all—veteran, novice, specialist and amateur, are supposed to be thinking about at present; and admitting that nothing new can be added to the *modus operandi* pertaining thereto, I will wave the plea of originality—that not being the import of my caption—and as what I write embodies my very humble opinions concerning the requisites of a successful wintering preparation, I submit them for what they are worth.

CONDITION OF THE BEES.

Bees should be healthy and embody all the other requisites of good colonies. We do not want bees that are constitutionally predisposed to ailments, that are liable to develop a deranged secretion when subjected to the aggravating changes atmospheric, dietetic, etc., that they must necessarily submit to, from the time they cease outside activity in the fall until they resume it again in the following spring. As to quantity, I am not radical. If I do not have bees enough to occupy six frames of comb, I can put up with four. I have wintered colonies from small late swarms, that were not crowded on three frames as successfully, and received as good returns from them the season following as from others that were a hive-full, all doing well, comparatively. The latter extreme I would not advocate as a status of strength; accepting it as a condition, allowable only, when obliged to submit to a stress of circumstances. Large colonies lose more bees in wintering, in proportion to numbers, than quite small ones, if the small ones are properly cared for.

Could I be allowed to decide the strength of my colonies for wintering, those of medium size, covering about six combs would be my standard for selection. Such consume less stores, proportionately than large ones, exhale less moisture, are less liable to create an abnormal condition during confinement, and, conditions alike, they will swarm as early and cast as strong swarms! Giant colonies, with 30 pounds of stores, "are not to be frowned at," but when the same results can be accomplished by a minimum, with two-thirds of the stores, and an extra five minute's care while preparing it for winter, the advantage to the bee-keepers seems to favor the latter. I would not divide the maximum, nor "double down" the minimum.

THE HIVE.

The kind of hive suitable to winter a colony of bees successfully, appears

to be of less decided importance than is generally purported, but as the movable-comb hive only is admissible in bee talk, I will admit all kinds in general, with their accompanying sized frames, and venture the assertion that no style of hive will alone winter a colony of bees. One of my colonies has passed the three preceding winters in a box-hive in as good condition, excepting the loss of more bees, as those in the movable-comb hives, I caring for both alike.

POSITION OF THE CLUSTER.

As soon as possible, after the bees have done storing surplus, I commence to prepare them for winter; my first steps being to locate the cluster at one end of the brood-chamber on combs, $\frac{1}{2}$ or $\frac{2}{3}$ of the lower portion of which is composed largely of empty cells. I then prepare a passage for the bees over or through the combs, close up what space I deem necessary with well-filled combs of capped stores, ending, if required, with a division-board. If the space left, after removing empty combs, or those not needed, is quite large, I fill it with chaff. By the foregoing described arrangement, the cluster is not liable to get divided, and the bees can move *en masse* in the direction of their stores, as they are all above, or on one side of them.

STORES.

For food I supply new capped honey, or sugar syrup, fed during the month of September, and as early in that month as possible. After feeding, I inform myself of the status of each colony, by a thorough examination. I then arrange everything inside of the hive satisfactory, tuck the quilts down snugly, or screw down the honey boards, and let the bees propolize to their satisfaction. During the remaining days in which the bees can fly, I feed sugar candy over the brood-chamber, or outside. This final feeding I have found to operate admirably; it attracts no attention of robbers, and supplies the bees with an excellent food which they will consume in lieu of their winter stores, while they are making their natural preparations, after having their domicils disturbed by over-hauling in the fall, when there is no nectar in the fields.

PACKING.

As soon as the severe frosty nights give warning of winter's approach, I fill the caps of the hives with chaff and straw, about $\frac{2}{3}$ chaff and the remainder straw, putting the chaff in first. I then put a few handfuls of straw on the quilts or honey-boards; put on the well-filled cap, and crowd all down as closely as possible.

This done, I surround the hive with a box having an opening in front. With a passage for the bees, and allowing them to become familiarized with their surroundings, I next pack chaff or straw around the backs and ends of the hives, leaving the fronts until steady cold weather demands further care—when all is completed by crowding the packing around the whole hive, about a foot in thickness.

To give a passage for air from outside, I bore two or more one-inch auger holes in front of the box, and high enough to prevent strong gusts from blowing directly into the entrance of the hive. A board closes the entrance to the box and completes the process.

UPWARD VENTILATION.

Unless the colony is above medium size, I give no ventilation over the brood-nest. If below the medium, I place a folded paper over the quilt, before crowding the cap down. When the colony is a large one, occupying eight of ten American or Gallop frames, I roll the quilt back, the distance of the space between combs, or bore three one-inch holes through the honey-board, at the end of the brood-chamber, opposite from the cluster, and cover the openings with a single thickness of burlap. To facilitate the escape of moisture from the caps, I have a $\frac{3}{4}$ inch auger hole in each end. As the processes described in the foregoing embody the "seven requisites" of a safe wintering, I cannot make a better conclusion than by stating that, having tried them five winters, I have not "found them wanting."

Cumberland, Me., Nov. 12, 1883.

For the American Bee Journal.

Different Varieties of Bees.

W. Z. HUTCHINSON.

The most exhaustive, and, to my mind, the most impartial and best article upon the comparative merits of the Italian and German varieties of bees, appeared in the April and May numbers of *Gleanings* for 1881. It was from the pen of the Rev. L. L. Langstroth. As many of the present readers of the BEE JOURNAL probably have not seen the article in question, I hope I may be pardoned for quoting the decisions therein recorded:

1. When late forage is scarce, the Italians stop breeding much earlier than the blacks.

2. The Italians, unless stimulated by judicious feeding, do not resume breeding as early as the blacks.

3. The Italians are much more inclined to build drone comb than the blacks.

4. The blacks are more ready than the Italians to work in surplus honey receptacles not closely connected with the main hive.

5. The comb honey made by the blacks from light-colored supplies, is usually more attractive than that stored from the same sources by the Italians.

6. With a queen of the current year, the blacks will hardly ever swarm, while, long after the usual swarming season, young Italian queens will often lead off swarms.

7. Black bees are much more sensibly affected by the loss of their queen than the Italians.

8. In building, an Italian colony seldom begins as many combs as the blacks, and, therefore, work them

more compactly, squaring them out, as it were, as they proceed.

9. Black bees will readily build between guide frames, worker combs, while it is very difficult to get any satisfactory result, in this line, from Italians.

10. The Italians, both young and old, adhere with much tenacity to their combs when they are lifted from the hive, while the blacks, more especially those newly hatched, tumble off so readily as to annoy the operator by crawling up his clothes, or exposing themselves to be trodden upon.

11. When the hive is opened, the Italian queen and workers are disposed to remain quiet, and when they are lifted out, the workers spread themselves over the combs.

12. Under adverse circumstances, the blacks are far more easily discouraged than the Italians.

13. The Italians, will, in some seasons, from the second crop of red clover, build new combs, and store them with honey, when black colonies, in the same apiary, are losing weight.

14. Italians suffer little, when compared with the blacks, from the ravages of the bee moth.

15. Italians are far less likely than the blacks to rob or be robbed.

16. The Italians, by their superior energy and greater length of proboscis, will, on an average of seasons, gather much larger stores of honey than the blacks.

After each of the above propositions Mr. Langstroth proceeded to enlarge, illustrate, explain, and go into details as only Mr. Langstroth can, and any one who cares a fig about the matter should send for the papers containing the article.

It will be seen that each of the above varieties possess superior qualities not possessed by the other, and that, upon a summing up, the Italians come out ahead, and for the production of extracted honey, they have no superior. It will also be seen that, for the production of comb honey, the German variety has some characteristics that cannot be successfully ignored. Now, if we can have a strain of bees possessing the good qualities of both races, with the undesirable traits left out, would it not be an upward step? Mr. Heddon asserts that by a judicious crossing of these two varieties, and a careful selection in breeding, he has obtained such a strain; and so well satisfied am I of the truthfulness of this assertion that I commenced, the past season, to stock my apiary with the "Heddon strain." I arrived at this conclusion from an actual trial of the bees. I am well aware that all over this broad land there is a genuine and worthy love for the Italians. I have felt this love, and know what it is, and only those who have "been there" know with what reluctance and real "heart aches" I give up the pure Italians, but self-interest compels me to.

With the Syrians my experience has been short and bitter—they are so irritable. It will be remembered that at the Northwestern Convention, a gathering that represented the largest number of large, practical,

successful honey-producers," that Mr. Langstroth had ever seen, the inquiry was twice repeated before any one could be found who had gentle Syrians, and then only one person was found, and he only knew that he had bought a selected, tested queen of a reliable dealer; the bees had the same appearance as the Italians. Somebody at the Northwestern Convention remarked that the Syrians had no good qualities not possessed by the Italians, while they had the unpleasant one of extreme irritability. But their admirers tell us that, if we will handle them properly, they will be gentle, and I presume they tell the truth, but who wishes to be obliged to approach the hive upon tip-toe, very slowly remove the cover, then sit down and wait for the bees to become accustomed to admission of the light, and then handle the frames so carefully that there is not the least jar? I will tell you who it is; it is the man who is not dependent upon bee-keeping for his bread and butter, but not the man who raises honey to support his family, and to whom minutes, at some times, may almost be dollars. I am heartily sick of that old saw. "If you will only handle them carefully, they are all right." No doubt of it, but we want bees that we do not have to handle with care; there are times when rapid manipulation, and a little thumping of frames, is absolutely necessary. The next count against the Syrians is, that they do not properly ripen and seal their honey. They are something like the Egyptian bees, whose honey sometimes looks very much like honey which has "sweated" from being kept in a damp place. I am aware that this complaint against them is not universal, but some of our largest producers have discarded the Syrians, and this point was one of the principal ones that influenced them in their decision. "Yes," says one, "but what have you to say to their wonderful prolificness, you do not doubt that do you?" No, I do not doubt it, but I dislike it; in my estimation it is a fault, and a very undesirable one at that. As some one said, at the last meeting of the Michigan State Association, "They will rear brood as long as a drop of honey remains in the hive." Is this a desirable quality? Their propensity to rear large quantities of brood at all times, and to build large numbers of queen-cells, just suits the queen breeder and the bees-by-the-pound man, but does it please the honey-producers? It is quality of bees that suits them, not quantity.

As A. R. Kolnke says, on page 560, "The prolificness of queens and the industry of colonies do not necessarily go together." We prefer bees that fill their hives with honey and then stop breeding (if the honey flow stops), to those that gather honey only to rear more bees that these bees may gather more honey to rear more bees. In other words, bees, not honey, is the great object aimed at by the Syrians; their philoprogenitiveness is greater than their acquiescence.

But, says another, "If they breed late in the season, they go into winter with a hive full of young bees." True,

again, but this is an undesirable state of affairs; and if this article were not already too long, I would demonstrate the fact; as it is, I will simply point to the fact that the Syrians die in winter just the same as other bees. But I will accord to the Syrians one good quality, and that is, they can be shaken from the combs "like shot from a shovel." To the gentleman of leisure this may not be an advantage, but to the man with aching back and arms, who shakes off a barrel or more of bees per day, this quality is quite an object.

Rogersville, Mich., Nov. 12, 1883.

CORRECTION.—In my article on page 594, third line from the bottom, "A thin strip of *bear* comb" should read: "A thin strip of *bruce* comb." The same mistake occurs in the 36th line from the bottom. In the second column, same page, 25th line from the top, "stay" should read *stage*.—W.Z.H.

Prairie Farmer.

Bee Fever, Selling Honey, etc.

MRS. L. HARRISON.

Bee-keepers, as a class, are very enthusiastic in their calling, and, as the science is continually advancing in the way of new discoveries and appliances, this tends to keep them so. All students of the profession have to be acclimated, as it were, for all beginners, whether young or old, are sure to be attacked by a malady known to veterans as "bee-fever." Some persons are subject to occasional returns of it, during their natural life, while others get entirely cured.

We love to call to mind our own experience with it. A minister, who combined bee-culture with preaching, seeing how badly we were affected, kindly laid his hand on our shoulder, saying, "Take care, take care, Sister Harrison; you are getting the bee-fever too bad." Poor soul, we have it yet, and are likely to have it as long as we are an inhabitant of a land of flowers and sunshine. Our partner in the sweets and stings often remarks, "If I ever get to heaven, I expect to see you coming around with a bee-hat on."

The best known remedies for this fever, are losses by wintering, poor honey seasons, and an unreliable market. Losses by wintering have become obsolete in the hands of a few skillful bee-masters, and they reap returns, even in a poor season, by an intelligent use of the extractor whenever a flow of nectar occurs for a day or two, and yet they fail to obtain "tip-top" prices for the product.

Novelties in the way of labels are the fashion now, its advocates claiming that in order to sell honey, it must be pleasing to the eye, look attractive, and be adorned with bees, flowers, and streamers gay. While it is true that goods should be attractive to sell well, there is a limit to adornment. Bolts of muslin are adorned with pretty lithographs of pearls, grapes, etc., but what sensible house-wife examines these when she is seeking a

good fabric for wear. She may say they are pretty, but then she directs her attention to the goods, holds it up to the light, examines the threads with a magnifying glass, and looks for the name of the mills. If we were wishing to purchase a package of honey to-day, in the market of Cincinnati, it would not be a novelty in the way of a label that we should seek, but the name upon it. C. F. Muth, of that city, has sold more honey than any person living, and it has not been by his labels either, but by putting upon the market pure unadulterated goods under their own name. Buckwheat honey is not sold as white clover, nor dog-fennel as linden. Mr. Muth has so educated his producers that they keep each kind separate and intact, and that enables him to call each by its Christian name. Where to-day are the dealers who, a few years ago, flooded the West with beautiful glass packages of pure glucose, adulterated with a piece of comb honey swimming in it, and labeled White Clover in gold letters? Are they to be seen adorning the shelves of grocers, with their gold-embossed labels? Bee-keepers do not need a monkey and hand-organ to attract attention, but their name stamped upon the white wood of the package of comb honey, or upon the keg, can, or barrel of extracted.

Honey that is shipped to cities is produced almost entirely in one and two pound packages, and shipped in crates with glazed sides. We lately saw one of these pretty crates in a grocer's window, and thought "beauty unadorned is adorned the most." Would it cater to the wants of the consumer if the white wood of these packages was covered with gayly tinted paper? Does he want to pay for it? Some one must, for it will come out of some person's pocket-book. These crates should be graded, and the same in the middle as shown next to the glass, and have the producer's name stamped on each one. A producer who has a reputation to maintain, will not be likely to put in the center of a crate stamped packages that are black in the center from being used as cradles for a generation of bees, and then filled in the fall with the juice from apple and sorghum mills, and honey from frosted buckwheat fields.

White clover honey has no superior, and should be graded as such, but linden, goldenrod, buckwheat, etc., are produced and relished by many, and should be graded and sold under their own name. A home market is necessary, in order to keep bees for profit, and if the producer has none, he should make one. Milk routes have a money value, and are sold according to their merits, and honey routes will have a pecuniary value when they are better understood.

We have noticed that when a family eats honey at all, considerable is consumed; while another family cannot be persuaded to buy a pound. Some bee-keepers canvass their own neighborhood, and leave a small package at each house, and build up a trade in this way. All undesirable lots can be worked off at home and better prices

obtained for it, than by shipping to distant cities.

Bee-keepers, as a class, have a mania for shipping to large centers, and the business has been injured in that way, as honey is sold there for less than in small towns. We have known of grocers in adjoining towns ordering honey from here, when we knew of producers near them that should have supplied them, and saved transportation.

Peoria, Ills.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Feeding Bees in Winter, etc.

1. What is the best way to feed our bees in winter, when we have them in a cellar, and know they have not enough to keep them through until spring? Many that were late swarms in this section, will be short of stores where they have not been replenished from stronger colonies; and, unless fed some during the winter, many colonies will starve. There was only enough fall honey to keep up a good brood.

2. Will the division-board feeder, as described in Prof. Cook's work, do for a winter feeder, or would it be best to feed from cups covered with cloth, bottom upwards, and placed over the frames? Please state the best and safest way, and oblige many, who from necessity or neglect, have deferred this great necessity until now.

J. W. SANDERS.

Le Grand, Iowa, Nov. 16, 1883.

ANSWERS.—1. I have never yet been able to feed bees in winter, or at any time, when they could not fly for a considerable length of time, to my satisfaction.

2. I have never tried Prof. Cook's feeder above referred to, but from my experience with those working upon the same principle, I should not dare to depend upon it nor the cups covered with cloth. A good feeder should combine the following qualities: It should not leak a drop, whether the bees desert it or not. It should not daub the bees. It should not waste heat, nor excite robbing. The great trouble with all feeders, with cloth attached, is that they do not hold the feed, when from cold or any other reason the bees abandon it for a time, then daubing and robbing follow. It is best to do all feeding necessary before the bees cease flying, but in your case I should use one of the three feeders I have devised, called a "Winter feeder." It differs from the other two I use, inasmuch as

the opening is very large, and the feeder very shallow. If the feed consists of pure cane sugar syrup, the bees will take it down to the combs in winter, if in the cellar and the feeder covered warm.

Moving Bees, etc.

Please answer the following questions through the BEE JOURNAL:

1. Can I, without loss, put my bees in a new yard (adjoining the old one) in the spring, when I take them out of the cellar, and what precautions will have to be taken.

2. Can extracted honey be shipped in barrels without waxing the same, and if they are waxed, how much wax will be required? M. E. DARBY.

Dexter, Iowa, Nov. 10, 1883.

ANSWERS.—1. Certainly you can, and that, too, without any precaution, nine times out of ten, though it will be well to remove all land-marks from the old apiary that you can conveniently, and place a board partially in front of the hives, but so as not to shade the entrances when you put them out for their first flight.

2. My experience in waxing barrels is that the wax costs as much or more than the barrel, and is not needed at all. A good wooden-hooped pork barrel, made tight by a good workman, will hold honey nicely. Mrs. Spades, the ex-lady honey dealer of Chicago and New York, told me that she was convinced that wooden-hooped barrels would hold honey better than those iron-bound. I, at once, changed to the cheaper barrel, and found her opinion correct in my case. Before filling a barrel, I always see that the hoops are driven tightly, and the outside ones nailed; the "outside" in each group. Pour in a gallon of hot water, and shake until it saturates each part. Pour out, then weigh the tare, and fill with honey, and weigh and mark all on the head of the barrel, and you are ready for an unexpected order.

A meeting of the bee-keepers of Des Moines Co., Iowa, will be held on the second Tuesday in January, at 10 a. m., for the purpose of organizing a county bee-keepers' association, at Middleton, Iowa, in R. C. Crawford's Hall. JOHN NAU, FRANK MELCHER, A. M. BALDWIN, W. R. GLANDON, Committee.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

SELECTIONS FROM OUR LETTER BOX

Seed of an Aster.

I enclose a package of seed that I obtained from a plant that is making its appearance here. It grows from one to three feet high, and blooms from the middle of August until frost kills it. The flowers are small; the outside being white and the centre yellow. The flowers look very much like the flowers of the May weed. The plant is very hardy, increases rapidly, and stands drouth better than other honey plants, and appears to stand next to sweet clover for secreting nectar. Sow the seed almost any place in the spring, and the plant will be apt to take care of itself; it is very hardy and will not winter-kill.

M. MILLER.

Scott Co., Iowa, Nov. 12, 1883.

[The plant is evidently an aster, but from the seed alone, nothing very certain can be said of it. Seed will be sown and report made, if favorable, next year.—T. J. BURRILL.]

No Fall Honey.

We had an exceptionally bad season in our immediate neighborhood. April opened, promising fine weather, but soon the cold set in, and in connection with raw winds, increased my winter losses to about 80 per cent. We had a very fine stand of white clover, but the bees did not gather any surplus until the latter part of July, and then it lasted but a few weeks. There was no fall honey. I received about 70 pounds of mostly extracted honey, per colony, spring count; but they are pretty well supplied with stores of white clover and Alsike honey.

G. E. T. KYBER.

Green Bay, Wis., Nov. 19, 1883.

No Surplus Honey.

The season of 1883, for bees in this section, has been a peculiar one. The spring opened very favorably, but May was so very wet and cold that the bees could not gather enough for brood-rearing. June was somewhat more favorable, then swarming commenced, and, by the time that was over, the drouth was here with cold nights; during August, on account of the cold nights and dry weather, no buckwheat honey of any account was stored, and the early frost in September cut all prospect for surplus out of the question. I do not think there was one pound of surplus, when last season there were ten pounds. Bees are now in winter quarters with honey enough, but weak in bees, and we are having a perfect blizzard here; it is already 18° above zero, and the wind blowing a perfect hurricane. Bees unprotected will suffer from this cold snap. I got but little surplus on account of selling nuclei, and using my bees for queen-rearing.

H. H. BROWN.

Light Street, Pa., Nov. 15, 1883.

Early Frost Cut off the Fall Bloom.

I commenced the season with 42 colonies; 5 were rather weak, and owing to the cold wet spring, they were all rather weak, when the white clover came. I extracted 4,000 pounds of extra fine honey; and increased to 80. The frost came early and cut off the fall honey. I sold one, and have the rest in the cellar (all Italians).

JOHN DEWAR.

Tiverton, Ont., Nov. 17, 1883.

Cellar Wintering of Bees.

In the fall of 1882, my 23 colonies were stored for winter, viz.: Seven were packed in chaff on the summer stands, and 16 were put in the cellar. They wintered well, and had plenty of honey left. I kept the cellar at a temperature of 35° to 45°. In one instance the thermometer fell to 32°, on which occasion the bees became very restless. Thinking the weather would continue cold for some time, I began to warm the cellar, by putting a bucket full of live coals on the cellar floor, several times a day. I noticed a great deal of dampness, and after using the coals, this dampness was removed, and the bees became quiet again. Before this was done, the moment the bees heard a noise, when we entered the cellar, they began to fly out and stir up things lively. In regulating the cellar, as above stated, I think bees will winter every time. I have 60 colonies packed into the cellar this winter. I began the spring of 1883 with 23 colonies; increased to 70; obtained 1,055 pounds of extracted, and 1,075 pounds of comb honey; in all 2,130 pounds; and average of 93 pounds per colony, spring count. My best colony, Cyprian, yielded 212 pounds of extracted honey. The fall season was rather poor; the bees did not do much after July 15, on account of dry weather.

JOHN NEBEL.

High Hill, Mo., Nov. 19, 1883.

Foul Brood.

Several packages of discolored bee-comb have been received in response to request. All except one are found to contain the same micro-organism. The exceptional one I do not know who sent; but it came in a piece of pine, and with a bored inch hole, and outside made octagonal. A few cells of the comb were wrapped in a strip of muslin, and put into the place provided in the piece of pine wood. In this specimen nothing of a living character has been found. Another specimen, sent in a stout paste-board box about 2½ by 3 inches, and labeled "Cobalt" was accompanied by a letter which I am sorry to say has been misplaced without reply. The indications are that in this latter there is genuine foul brood. Should be pleased to know again the correspondent sending the specimen. So far there is nothing to indicate a difference between so-called malignant and mild types of the disease. Private replies have been sent to most of the receipts, but I here return many thanks for the specimens sent.

T. J. BURRILL.

Champaign, Ill., Nov. 17, 1883.

Bee-Keepers Produce the Beeswax.

They are now the greatest consumers of this one of their own production. In getting their wax to the foundation mills and back home, does it pay them to have the grocer, peddler, commission merchant and general dealer in wax, etc., each take a margin out of them? Just think the matter over, and form correct conclusions.

JAMES HEDDON.

Dowagiac, Mich., Nov. 17, 1883.

Poor Season for Bees.

This has been a poor season for bees here. We have had only a quarter of a crop of honey, and very little increase. It was so very dry that bees could get no nectar. Enclosed I send a plant on which bees work every morning. What is it? G. HILLJIE.

Sohnlenburg, Tex., Nov. 17, 1883.

[It is figwort, or the Simpson honey plant.—ED.]

Strange Bees.

A negro man lately came to me and asked me to buy a bee tree he had found, near my house. I bought the tree for 50 cents, and went to cut it. As bees had done so poorly, and had so little honey, I thought the combs would not break down, but every comb broke down, being so full of honey, and, to my astonishment, I noticed they were a strange kind of bees, being larger than the common bee, and having one and two yellow bands around their bodies, and had between 30 or 40 lbs. of honey; nearly twice as much as my home colonies have. I put them in a clean hive, and I am feeding the honey back to them for winter. They must be splendid honey-gatherers to get so much in such a year as this. They were no nearer the swamp than my bees. I know that bees have gathered all their honey from the swamp, this year.

W. S. DOUGLASS.

Lexington, Tex., Nov. 10, 1883.

Explanation, and Report for 1883.

On page 548, of the present volume, you will see that I obtained 75,000 pounds of honey from 60 colonies of bees, spring count. That is a mistake, omit one cipher and you will have the correct amount. That Dr. J. C. Thom, of Streetsville, Ont., on page 563 of the present volume, did not understand how that was done, is no wonder. I can only say it was done, by adding a cipher. I will give my brief report for the season, just passed. After coming through the spring, by loss and selling, I found myself the possessor of 60 colonies of bees, most of which were in good condition. By the last of May, some of the hives were filled with bees to overflowing, and ready to swarm. Not being in favor of swarms on fruit blossoms, I commenced to equalize them by taking from the strong and giving to the weak: in this way I kept back swarming until June 15, when out came four swarms, followed by from one to five swarms a day, until June 28, when I made what swarms I thought best by dividing. July 4

found me with 100 colonies, 90 of which were given sections, and 10 prepared for extracted honey (4 new and 6 old). The bees worked hard on clover, but the nectar was very thin and they did not gain very fast. On July 20, basswood blossomed, and then the bees worked early and late, rain or shine, for 24 days, when all was over; after which they hardly got as much as they consumed. Sept. 1, honey all taken. I find that I have 2,500 two-pound solid sections of white honey, and 2,500 pounds of extracted, making a total of 7,500 pounds of honey from 60 colonies in the spring. This fall, I made by doubling my nuclei, 6 more. So that now, in all, I have 106 colonies in good condition, packed in chaff for winter.

J. H. KENNEDY.

Little York, N. Y., Nov. 19, 1883.

My Report for 1883.

As I did not make a spring report, perhaps it would not be out of place now. The first of June found me with 30 fair colonies, out of the 45 put in the cellar on Nov. 20, 1882. The second day of March was the only day between Nov. 20 and April 5 that the bees could fly. At that time every colony I had was suffering badly from dysentery, and a number of them were dead. As the day was warm and pleasant, I set them all out, and such a mess! In a few minutes the snow was completely discolored, and you could smell it 10 or 15 rods from the yard. After an hour's flight, I began feeding them sugar-syrup, which I prepared and warmed by tipping up the front of the hive and pouring it in at the entrance, giving each colony 5 lbs. of syrup, which was all taken up before I set them in, in the evening. I saw no more of the disease during the rest of the winter. I set them out on April 5. Now for the results of my season's work: I took 2,000 lbs. of comb honey, in two-pound sections, and 1,250 lbs. extracted; all from the Alsike clover and basswood. I increased to 56. The honey is mostly sold in my home market, at 15 and 20 cents per pound. My queens are all bred from Mr. Doolittle's best strain.

WM. BERRYMAN.

Geneva, N. Y., Nov. 18, 1883.

My Surplus Arrangement.

I have been a reader of the BEE JOURNAL for one year, and think every one that keeps bees should have it, for it will more than pay. I see that most of the bee men use a case to hold sections. Some say I have the case, and no doubt of it; others seem to doubt it considerably. I do not use a case at all, nor separators either, and I have not had enough crooked or bulged sections for table use, this season. I do not say that I have the best surplus arrangement in existence, but one that is cheap, and any one can test it for themselves. I use a slot honey-board, Langstroth hive, and one-pound sections. The honey-board prevents the bees from gluing the outside of the section, except at the entrances. I place seven sections in a row. I have glass cut

the size I use, 4 $\frac{1}{2}$ x4 $\frac{1}{2}$; I place one at each end of the row; then take a common rubber band or cord and stretch it around a row of sections and glass, and you have the arrangement complete. I use four rows or 28 sections for one tier, and I tier them up 2, 3, and 4 high, using 112 sections on a hive at once, if needed. Bee men from several counties have visited my apiary this season, and all like the arrangement first rate, and went home and tried it. One said, "It is the nicest thing I have ever tried." Another said, "I will never use another case, as long as I keep bees."

FRANK E. THOMPSON.

Tiskilwa, Ill., Nov. 16, 1883.

From 8 to 20, and 500 lbs. Comb Honey.

I commenced the season with 8 colonies of black bees; increased to 20, and got 500 lbs. of comb honey in two-pound sections; for which I found ready sale at from 15 to 18 cents per pound, near home, and could have disposed of much more at the same price, if I had it to sell. I procured a tested Italian queen from Henry Alley; introduced her early in July, and Italianized one-half my colonies later in the season. J. A. BLACK.

Pleasant Mound, Ill., Nov. 19, 1883.

A Question for Mr. Stewart.

On page 576 of the BEE JOURNAL, is a very interesting article by Mr. W. H. Stewart, entitled, "Shall we Clip our Queens' Wings?" at the close of which he says: "If I were offering queens for sale as superior stock, I would compel the brood mothers to fly often, even if I had to toss them up to give them a start." I wish to ask him a question to illustrate the matter in a different light. Suppose that he had a brood mare from which he wished to rear colts noted for speed, would he consider it necessary or advisable, during foal, that she be driven at a high rate of speed, with a view of transmitting that quality to the offspring? W. N. HOWARD.

Derby, Vt., Nov. 19, 1883.

The Michigan Convention.

DEAR MR. EDITOR:—May I ask you to call special attention to our next annual meeting to be held in Flint, Dec. 5 and 6, of the Michigan Bee-Keepers' Association. We expect to have by far the best meeting ever held in the State. It is expected that the Rev. L. L. Langstroth will be present. To see and hear him will pay any one for the trouble and expense incident to the journey. We also expect D. A. Jones, A. I. Root, C. F. Muth, and hope to have C. C. Miller and T. G. Newman. From what I hear, Michigan bee-keepers are to be out in force. Hotel rates are to be \$1.00 a day. Further particulars as to programme, will be given soon. We expect to get reduced rates on the railroads. To aid in this, and that I may know how many certificates on railroads to ask for, will every one in this or other States who expect to come, drop me a card at once to that effect?

A. J. COOK, President.

[Sorry we cannot attend.—ED.]

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper, shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter, on your label, notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a statement of account every week.

Our New List of Premiums.

Getting up Clubs for 1884.

To increase the number of readers of the BEE JOURNAL, we believe, will aid progressive bee-culture and help to elevate the pursuit. We, therefore, offer the following premiums for getting up clubs:

While no subscription to the BEE JOURNAL will be taken for less than the regular advertised prices (viz.: Weekly, \$2.00; Monthly, \$1.00),—any one getting up a club of two copies, or more, may select from "OUR BOOK LIST" anything therein named, to the amount of 15 cents for every dollar *they send direct to this office*, to pay them for the trouble of getting up the club; and these books will be sent, postpaid, to any address desired.

For a club of 3 Weekly or 6 Monthly and \$6.00, we will make an *additional* present of a Pocket Dictionary, bound in cloth, containing 320 pages.

For a club of 5 Weekly or 10 Monthly, (or a mixed club of both,) with \$10, we will, in addition to the 15 per cent, present a copy of the AMERICAN "POPULAR" DICTIONARY, comprising every word in the English language that enters into speech or writing; it contains 32,000 words and phrases, 670 illustrations and 512 pages; it is nicely bound in cloth, and will be sent by mail, postpaid, to any address desired.

For a club of \$20, for 10 Weeklies, or an equivalent in Monthlies, we will present, besides the 15 per cent. in books, a tested Italian queen, by mail, postpaid.

Announcements for larger clubs will be made hereafter.

Subscriptions for two or more years for one person, will count the same as each year for a different person.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

Bee Pasturage a Necessity.—We have issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for ten cents.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

A Chance for Fun.—The "latest thing out" in the way of something to afford home amusement for winter evenings, or a side show for church fairs, consists of a sort of Magic Lantern that does not require pictures on glass. The Polyopticon, as it is called, because it will show up so many different things, makes use of ordinary newspaper pictures, family photographs, chromo cards, home-made sketches, etc., and thus affords a new use for the collections of pretty cards, which so many have been industriously making. Though patented, it can be made and sold at one-fourth the price of a good Magic Lantern.

Descriptive circulars can be obtained of the Murray Hill Publishing Co., 129 East 28th St., New York City.

It would be a great convenience to us, if those sending us Postal Notes or Money Orders, would get the issuing Post-master to make them payable at the "Madison Street Station, Chicago, Ill.," instead of simply "Chicago." If they are drawn on Chicago, they go to the general office, and we have to make a trip of six miles to get them cashed; but if they are drawn on the Station as above, it is only a few steps from our office. When sending us money, if you will please remember this, you will much oblige the publisher.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

We need the numbers of the BEE JOURNAL for August, 1866, and April, 1876. Any one having them to spare, are requested to send us a Postal Card. We will give 25 cents for each. Do not send them without writing, for we want only one of each; and, if we are not already supplied, we will take them.

Speak a word for the BEE JOURNAL to neighbors who keep bees, and send on *at least one new* subscription with your own? Our premium, "Bees and Honey," in cloth, for one new subscriber to the Weekly, or two for the Monthly, besides your own subscription to either edition, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

It must be understood that, should an advertiser desire to cancel an unexpired contract, he can do so only by paying regular rates for the number of insertions his advertisement has had.

SPECIAL PREMIUM!

Five Octaves, four sets of Reeds of two and one-half octaves each, eight hand and two knee stops, as follows:

DIAPASON.
CELESTE,
TREBLE FORT,

MELODIA.
ECHO HORN,
BASS FORTE,

VIOLA.
DUCKET,
KNEE SWELL,
GRAND ORGAN.

Height, 5 feet 11 inches; width, 4 feet 2 inches; depth, 2 feet; weight, boxed, 350 lbs. This Organ is unexcelled for purity of tone, durability and beauty, and is fully warranted for five years.

This Organ will be shipped to the order of any person sending us a Club of **One Hundred Subscribers** to the **Weekly BEE JOURNAL**, accompanied by **\$200.00 Cash**, or its equivalent of Monthly and Weekly Subscriptions combined.

This liberal offer will remain open until June 1, 1884, and presents a fine opportunity to energetic persons to secure a handsome Organ without cost.

Subscriptions and remittances may be sent in at any time, and will be credited to this Premium, when so stated.

FOR SALE.

Barnes' Combined Foot-Power Saw,

Gig Saw, 2 Mandrels, 2 Emery Wheels, 3 Cutter Heads. Total cost, \$52.00. I will sell at 40 per cent. discount. Also one Mandrel, for power, \$5.

THE AMERICAN BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Northwestern Convention—Hints.

We have received the following letter from Mrs. L. Harrison, the Vice-President of the Northwestern Bee-Keepers' Society, offering a few hints concerning the next Convention:

DR. NEWMAN.—*Dear Sir:* I feel as though I was indebted to you for the pleasure and profit derived from the late Northwestern Convention. The air of the hall, at one time during the first day, became so impure that I was obliged to leave the room, and I thought, as I had seen Mr. Langstroth, I would take the first train for home, and say nothing about it, as I would only be laughed at, and called hysterical if I did. You then opened the windows, and relief came.

It must be apparent to you, as well as others, that after discussions have been prolonged from an hour and a half to two hours, that the audience becomes dull and lifeless, but if a recess of 15 minutes occurs, and the door is opened, which forms an excellent draught, the hall is cleared of impure air; and when business is again resumed, all engage in it with a keen zest. On the second day of the Convention, the air was as pure in the hall as it was out of doors.

Permit me to say to those who were not in attendance, that they missed a rare treat, by not being there. All present seemed to have come to get and impart information, and a universal good-fellowship prevailed. More ladies were present than at any Bee Convention I ever attended; and it is to be hoped that all those who were not able to bring their wives and daughters with them this year, will keep a few more bees another season, for the express purpose of paying their expenses to the re-union of 1884.

When we are having blanks printed—for to save time in the election of officers—would it not be well, to have some printed for statistics?

LUCINDA HARRISON.

Peoria, Ill.

The points made by Mrs. Harrison are well taken. On the second day of

the Convention we had one or two of such recesses, and noticed their good results. It will be well for the officers of the many Conventions, which will be held within the next few weeks, to take the hint. A few minutes for recreation and social conversation among those present, in every hour during the sessions, will be productive of more good than long and continuous sessions, without such a recess.

We second the motion for blanks to be circulated in the meeting upon which the statistics can be taken from all in attendance. Several were not present at the session when the statistics were taken at the last meeting in Chicago, and they were not, therefore, included in the table. This suggestion, if carried out, will enable the Secretary to obtain all the statistical information desired, from all those who are in attendance.

Pure air is also an essential element of a Convention—and we certainly favor "upward ventilation" in a hall when filled with a "swarm of bee-keepers." Impure air affects us very much in the same manner as it does Mrs. Harrison, and many others. We cannot endure it.

Small Sections for Honey.

Mr. F. L. Dougherty, in the *Indiana Farmer*, gives his opinion of the one and two pound sections thus:

That the larger sizes of sections for comb honey must go, we think is no longer a question of doubt. One pound sections are selling to-day in the market for 2 cents more per pound than the larger sizes. In fact, the larger sizes are a drug on the market, while the one pounds, 4½x4½, find ready sale at the 2 cents advance in price. We have struggled hard against this result, as we believed more honey could be secured per colony with the larger than with the smaller sections, and, in the absence of the smaller sizes, we have always disposed of the larger ones very nicely, but one lot of small sections would disturb the market for many days at a time. The laws of trade are invariable, and must be conformed to.

Two Little Bee-Keepers Gone.

A letter from Mr. E. L. Fredenburg, Fentonville, Mich., informs us that his two little sons (Roy and Freddie), were attacked by that direful disease, diphtheria, and both are now numbered with the dead. The BEE JOURNAL sympathizes with the bereaved parents, and offers its condolence. Mr. Fredenburg, with a heart full of grief, says:

"Oh! dear editor, you no doubt received my card, informing you that I was called home on account of the sickness of my family. When I left home I kissed my little 'Roy' for the last time, for he was dead when I arrived home again, and Freddie died the next day. Both had that dreadful disease, diphtheria. Roy was two years of age, and Freddie five. They were always delighted to help their 'Papa' when I was working among the bees, handing me different things I may want. They would watch the bees, going to and from the hives, with the greatest enthusiasm. But these two little lovers of the honey-bee have gone to their rest, in Heaven, forever. My heart is full of grief. Please make a note of this in the BEE JOURNAL, so that my bee-keeping friends may know of my sad loss."

It is not Dead, but Sleeping.—Not having received a copy of the *Illustrate Bienen Zeitung*, of Zurich, Switzerland, since June, we supposed it dead, and so mentioned the matter on page 539. Last week we received the September number, and, just as we go to press, we have the one for October.

✍ A correspondent asks if any one may select a Binder for the BEE JOURNAL, among the books given as Premiums for getting subscribers we reply, yes; any book or binder we keep for sale, may be selected by those who get up clubs.

✍ The semi-annual meeting of the Keystone Bee-Keepers' Association, will be held at Scranton, Pa., on the second Tuesday of December (11th). Our present membership is 36.

Popular Ignorance about Bees.

Mr. S. H. Clark, of Delavan, Wis., has sent us the following item from a New York paper, which shows very clearly the popular ignorance about bees. It is headed:

AN IMPORTANT DISCOVERY.

DECKERTOWN, Sussex County, N. J., Aug. 4.—A great quantity of honey is made in this and the adjoining counties. The principal producers are Mr. T. L. Babcock, of Vernon, this county, and Mr. Wisner Utter, of Amity, Orange County, N. Y. The production of honey, this year, will not be as large as was anticipated; the season having been too wet. The bees had an early and good start in the spring on apple, peach, pear and cherry blossoms, and more recently worked on basswood and sumac. During the past month they should have been actively working on white clover. The latter has been plentiful, but the season has been so wet that this flower has not yielded its usual harvest of sweetness, and, as a consequence, the bees of late have been nearly idle, except in the work of making wax—which is the employment of bees during idle seasons—and the slight work which they have been enabled to do on other flowers....

A discovery which Mr. Babcock claims to have made, is of great interest. It is the cell, and not the egg, that determines the sex of the bee. This summer, wishing to stop the excessive swarming from one particular hive, he cut from the combs all the queen-cells, leaving those for the drones and neuters. Soon afterward he discovered that the bees were converting some of the neuter cells into queen-cells, the egg that had been previously laid in each for a neuter remaining. He let the bees go ahead. When the time came for hatching out the eggs, he cut out the cells and they hatched out queens while he was watching them. Two days before

these queens were hatched out, he heard the queens calling each other. This is something that he had never before noticed.

The idea of bees "making wax" during "idle seasons!" Bee-keepers will enjoy a hearty laugh at the folly of Mr. B. and that newspaper reporter who was gulled by him!

The *best joke* is that important discovery!! It is truly wonderful, and Mr. B. is entitled to a "leather medal" for making it! To use the language of the reporter, Mr. B. actually "discovered that the bees were converting some of the neuter cells into queen-cells; the egg that had been previously laid in each for a neuter, remaining. He let the bees go ahead, and when the time came for hatching out the eggs, he cut out the cells, and they hatched out queens, while he was watching them." Had Mr. B. troubled himself to read the bee literature, he would know a great deal more about the habits of bees, and would have been saved the *ludicrous* position he now occupies, while trying to palm himself off as a "discoverer" of that which has been known for ages! and that, too, which the merest novice is quite familiar with.

Of course he made a *discovery*; he heard the queens calling each other—"something" never before noticed!" Such ignorance is inexcusable in this Nineteenth Century, under its full blaze of intelligence! Had it been written a thousand years ago, there *might* have been some excuse for it, but now there is *none*.

Prof. Hasbrouck should send a missionary down to that benighted locality, in his State, to save the wonderful "discoverer" from making himself a *laughing* stock for a world!

 The annual meeting of the Cortland Union Bee-Keepers' Association will be held in Cortland, N. Y., on Tuesday, Jan. 8, 1884.

M. C. BEAN, Sec.
McGrawville, N. Y., Nov. 23, 1883.

 To all *new* subscribers for the Weekly BEE JOURNAL who send us \$2.00 for 1884, we will send the remainder of this year *free*, from the time the subscription is received. So, the sooner they subscribe, the more numbers they will get *free*.

 We regret to learn that Mr. Jerome Twitchell, of Kansas City, Mo., was severely injured last Thursday by a falling wall.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL.
Monday, 10 a. m., Dec. 3, 1883.

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY—The market is slow; arrivals exceed the demand which, however, has improved some. There is a better demand for comb honey, and supplies are short, which, no doubt, is temporary, as usual. Last year at about this time, comb honey was at its highest, when our sanguine friends very naturally held on, expecting more. However, large supplies commenced to arrive, and prices kept going down steadily. Bee-keepers in general bent their energies on the production of extracted honey last season, more than ever before. We had a large crop, and extracted has been dull so far, not only because of the large supply, but because manufacturers complain of dullness in their business. Consequently, we have reason to believe that the present slow market is temporary.

The present state of the honey market gives our bee-keeping friends another chance for a disappointment, to-wit: That of over-production of honey another season. This is merely an idea of my own, and our friends may take it for what it is worth.

Extracted honey brings 7@9c. on arrival. Best comb honey, 16@17c. in small sections.

BEESWAX—Is of ready sale at 28@30 on arrival. CHAS. F. MUTH.

NEW YORK.

HONEY—White clover and basswood in 1 and 2 lb. sections, 17@21c. Dark and second quality, 14@15c.; extracted white clover in kegs and barrels, 9@10c.; dark, 8c.

BEESWAX—Prime yellow, 27@29c.
H. K. & F. B. THURBER & CO.

CHICAGO.

HONEY—The market remains without change from that of last week. Dealers and retailers buy only enough to supply the demand for present use. It is impossible to place lots, or entire shipments, owing to the reluctance of dealers to pay in advance of immediate want. Prices obtained for white comb in 1 lb. sections, 18@20c.; 1½ and 2 lb., 13@18c. according to beauty of same. Extracted honey, 8@10c. per lb., according to color, body and flavor.

BEESWAX—Yellow, 33c.; medium, 28@30c.
R. A. BURNETT, 161 South Water St.

KANSAS CITY, MO.

HONEY—Receipts of comb honey has been more liberal for the past week, but the demand still keeps every thing that is of fair quality well cleaned up. Choice 1 and 2 lb. sections are taken on arrival at 18c.; larger sections and dark honey 16@17c. Sales of extracted for the past week, about 4,000 lbs., mostly at 8 cts. The feeling for extracted is a little better, and I look for a firmer market.

JEROME TWICHELL, 535 Delaware Street.

SAN FRANCISCO.

HONEY—There has been some attempts at negotiation in comb honey on Eastern account this week. The market for extracted is dull, and it is doubtful if more than 7½c. could be realized for choice water white in a wholesale way. White to extra white comb, 16@18c.; dark to good, 12@14c.; extracted, choice to extra white, 7½@8c.; dark and candle 1, 6½@7c.

BEESWAX—Wholesale, 27½@30c.
STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Choice comb in light supply, fair demand and firm at 15@17c. per lb.; dark, broken and poorly handled, dull at less. Strained and extracted steady at 6½@7½c.; choice in fancy pkgs. more.

BEESWAX—Salable at 28c. for prime.
W. T. ANDERSON & CO., 104 N. 3d Street.

CLEVELAND.

HONEY—Choice honey is in excellent demand now. Every lot received thus far in good order, has been sold on arrival; best 1 lb. sections bringing 18c. quickly, occasionally 19c.; 2 lb., 17c. with an occasional sale at 18. Second quality and broken lots are very hard to sell. Extracted honey not in demand.

BEESWAX—28c.
A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—Our market is very quiet on honey. We quote 16@18c. for best 2 lb. sections—18@20c. for best white 1 lb., and 10c. for extracted.

BEESWAX—We have none to quote.
BLAKE & RIPLEY, 57 Chatam Street.

Ventilation of Cellars.

W. Z. HUTCHINSON.

Before the ventilation of my cellar, the air in it had a close disagreeable odor, and if bees were placed therein, the disagreeable odor was increased, and especially so if the bees suffered from dysentery. Two years ago I made arrangements for a thorough ventilation of the cellar, and since then the air in it has been as pure and sweet as it is in any part of the house. Last winter 14 colonies of bees died from dysentery, in the cellar, and yet, upon entering the cellar, not the slightest odor could be detected.

To remove the impure air, a 2½ inch pipe connected with the kitchen stove pipe was extended down through the floor to within 4 inches of the cellar bottom. That part of the pipe below the floor, and ¾ of that above, was made of wood, the remainder of iron. The pipe was furnished with a damper, which could be opened or closed at pleasure. When first starting the fire, or if at any time it burned low, and we wished to start it up again, the damper was closed, which increased the draft in through the stove. At other times the damper remained open, and the draft that otherwise would have passed through the stove, passed through the pipe; and, as there was less draft through the stove, there was a saving of fuel. The draft through the pipe was often strong enough to carry up light pieces of paper when placed under its mouth.

Please allow me to digress long enough to say that the coal stove, in my sitting-room, is furnished with a similar pipe, only larger, that extends down to within 2 inches of the sitting-room floor. When this pipe is open it ventilates the room by drawing the cold air from the floor, and also effects a saving in fuel. A neighbor, who has a similar stove, but without the ventilating arrangement, burns a ton more coal during the winter.

To furnish the cellar with pure air, the cellar drain was opened to a distance of about 70 feet, and 6-inch tile substituted for the small size. At the point of junction between the two sizes of tile, there was built up, with brick, a sort of "well," which was covered with a wooden ventilator similar to those built upon barns. When the outside temperature was down to zero, the air blowing in through the six-inch tile would be warmed to above the freezing point.

While I consider the ventilation of cellars and houses an excellent thing, I very much doubt its very materially affecting the health of our bees. For two years I have successfully wintered bees in clamps, where there was no ventilation except what came through 18 inches or 2 feet of earth. It is my

opinion that the primary cause of dysentery is in the food.
Rogersville, Mich.

For the American Bee Journal.

New Jersey and Eastern Convention.

Reported by J. Hasbrouck, Sec.

The meeting was called to order at 11:30. Roll called. By vote, the Secretary's report was dispensed with, as it had been read by all present. President Thompson delivered his address. He reported that his daughter, who had manipulated his bees, was greatly in favor of the Cyprian and Syrian bees. She finds them much gentler to handle, and more easy to get off the combs. She can manipulate at the rate of 10 colonies of these races to 7 of the Italians. Four Syrians yielded 247 lbs., 4 Cyprians 297 lbs., and 4 Italians 142 lbs.

Mr. L. C. Root, who was present, was elected an honorary member, and invited to take part in the discussions of the meeting.

Mrs. Thomas, of Tacony, Pa., was received as delegate from the Philadelphia Bee-Keepers' Association, and was also elected an honorary member of the Society.

The very interesting report from the President's apiary was then discussed.

Mr. Cook said, he understood that the new races were remarkable for productiveness, and believed that their chief advantage would be in crossing them with our best Italians. He had a Syrian queen, and intended to try these crosses.

Much interest was manifested to hear the opinions of Mr. Root, who responded by saying that we had claimed too much for the Italian bee, but yet, in his opinion, the Italian still stands at the head of races. The principal reason was, that they had been improved in this country by great care in breeding them. His experience with Cyprians had not been good. They breed so late in the fall, and hold drones so late, that they used up too much honey uselessly. The tendency to late breeding, in bees, was good, but the Cyprians overdid the business. He had no doubt that the introduction of this new blood, crossed with Italians, might result in improvement.

Mrs. Thomas was quite in sympathy with the views of the last speaker. There was something good in each race. She felt an attachment to the black bee, but not for honey. She had learned, in a visit to Mr. Alley, that he considers them best as nurses for queen-rearing. She thought the Italians, Cyprians and Syrians were very similar. She had seen the Italians in their own homes, and she had noticed that they do much better in this country. She reported that she had taken an average of 100 lbs. to the hive, the past season, and 150 pounds from each of 2 colonies. She thought the honey industry in its infancy, and thought that its importance ought to be brought to the attention of the public, particularly at fairs. She said

the managers of fairs needed to be informed, so that they might know what arrangements to make to insure proper exhibitions of bees and honey. She had been judge for a long time in the Department of Industrial Insects and their Products, such as honey-bees and silk-worms, of the Pennsylvania State Agricultural Society. Everything has more attention given to it than bees. To illustrate the want of knowledge in the managers of this industry, she said there was a premium offered for the best honey extracted in the presence of the committee.

The Secretary said that he was much interested in the President's report, and much surprised at it. He had had quite extensive experience with the two new races of bees, but found that they could carry only about half the load of honey of an Italian; that their tongues were shorter, and that they were exceedingly unpleasant to handle on account of their stinging ability. His queens were imported ones, direct from Mr. Jones. He believed that most of the stock sold for Cyprian or Syrian bees, were extensively crossed with Italians, and that they were good and desirable in proportion to the Italian blood in them.

Mr. Cunkey could substantiate the statement that the Syrians were easy to get off the combs, but they all went into the air, and directly for your face.

Mr. Cook had exhibited bees at the New Jersey State Fair at great trouble and expense, and loss of bees, with little competition, and without much encouragement. He had come to the conclusion that it was impracticable to exhibit bees at fairs.

Mr. Tompkins said that if the business were properly presented to the managers of the State Fair, he had no doubt but that the proper arrangements would be made by them for exhibits, that would be satisfactory and advantageous. He had read of bees being an annoyance, at a fair in Ohio, to those who kept confectionery stands. Provision ought to be made by the exhibitors of bees to avoid such things. The public ought to be instructed about the honey industry. Statistics ought to be gathered, and could be, and ought to be circulated so as to give the industry its proper influence.

Mrs. Thomas said it was perfectly practicable to exhibit bees in the midst of an exhibition, if the bees were given an outlet through a long tube, as she had seen it done, and it formed the most interesting part of the fair.

The President said the greatest difficulty in the way of proper encouragement by the agricultural societies, was that the business is not appreciated by the public. The managers would provide for anything in which the people were interested. The reason that horse-racing was the principal part of agricultural fairs, was because the public demanded them. We must begin with the people; we must educate them.

Mr. Cook moved that a committee of three be appointed by the Chair, to

draft a list of premiums and present them to the managers of desirable agricultural societies and endeavor to get them incorporated into the catalogues of those societies. Passed.

The meeting then adjourned, for lunch, till 2 p. m.

AFTERNOON SESSION.

The following new members were enrolled: P. E. Reiman, Pedricktown, N. J.; C. W. M. Burroughs, Hillsboro, N. J.; E. K. Dean, Amenia Union, N. Y.; W. B. Treadwell, Riverdale, N. Y.

The following was then read by Mr. J. H. M. Cook, of Caldwell, N. J., on

THE SPRING MANAGEMENT OF THE APIARY.

I select the subject of spring management because I believe that this is the season when our bees require the most careful attention, and that our crop of honey will depend very much on the skillful management of the apiary at this season. I use the term apiary because I think that a large number of colonies can be managed to better advantage than a few, and if I can be the means of eliciting your hearty discussion and severe criticism, I will not have written in vain. I will state that the object to be obtained, and for which the methods described directed, is the production of comb honey. I advance no idea, but such as I have put to a practical test, and proven successful.

We will suppose that our bees have been wintered on their summer stands, as is the usual practice in New Jersey, and are in fair condition. We cannot expect that they will all be in equally good condition—at least, I have never found them so. There are numerous causes to create this difference in our colonies, which we cannot control as we would like, and we must take facts as they are. I would make a general inspection of the colonies, about the 20th of March, or as soon as the weather is warm enough to allow the bees to fly and return to their hives, without being chilled, and ascertain their condition, making a note of it for future reference, and remove all drone combs, if any has been allowed to remain. If any are found short of stores, they should be supplied. This can be done by removing the empty combs, and replacing them with full ones, or combs filled with sugar syrup. If any are queenless, they must be supplied with queens in some manner, being careful to return the chaff or other packing to keep out the cold wind.

I do not think much of upward ventilation at this season. If we are sure that all have plenty of stores, we need not visit them again until the weather is settled and warm enough to remove the packing, and otherwise clean the hive, which we can generally do about the middle of April. We are then ready to commence the campaign. The old adage of the plowman, "To make haste slowly," is equally applicable to the bee-keeper, as it is very injurious to expose our bees to cold in early spring. We should now examine each hive about once a week, spread the brood and

place a comb of uncapped honey in the centre, which will cause the bees to feed the queen, and induce her to lay more eggs, and also give her an opportunity to lay in the centre of the brood-nest. But the spreading of the brood must be done with care and judgment, as the brood will get chilled, if the colony is not strong with bees.

I would not advise spreading it if there is not brood in four frames, and then not to place in more than one comb in the centre. The stronger the colony, the faster you can increase it. "Unto him that hath shall be given." By this means we will get our large colonies strong enough to receive the surplus boxes in fruit-blossom time. As the fruit-blossoms are beginning to open, I would put the sections on all colonies that have the brood-chamber three-fourths full of brood, and well-filled with bees. Place sections only on top, using only those sections filled with comb remaining over from last year, as we must not expect them to build much comb thus early in the season. If we feed a little just before fruit blossoms, it will be well, as the queen will lay faster, and the bees will fill the empty cells of the brood-chamber, and be compelled to store all the fruit-blossom honey in the sections.

I have, in this way, secured 25 pounds per hive of choice fruit-blossom honey in sections. If the prospect of fruit-blossom honey is good, it will, perhaps, pay to double up some colonies which are too weak to go into the sections. This I would do by taking one frame each from several strong colonies, and adding them to the weaker ones, that we wish to box, but, unless the prospect is good, it will not pay as it weakens the others very materially.

During the last of fruit blossoms, we may expect our first swarms from the stronger colonies, and I would allow them to swarm naturally at this season, as I wish to secure all the queen-cells fully matured as early as possible, in order to form nuclei for queens. When the early swarms issue, I hive them upon the old stand on frames of foundation, or, which is better, on combs, putting the surplus sections from the old hive upon the swarm, and removing the old colony, and I divide the brood and remaining bees into as many nuclei as possible, giving each a queen-cell and two frames of brood, and place them where we wish our increase to stand.

In this way I would manage all my early swarms until I have about as many nuclei as I expect increase of colonies, and as there is generally a scarcity of honey till white clover, it is well to feed the nuclei; and I will say here that I would not attempt to increase to more than one-half the number of old colonies, as we must keep our colonies strong if we would have box honey. When I have about enough nuclei formed, I continue to hive upon the old stand, placing the sections upon the new swarms as before, but instead of forming nuclei, I divide the brood among the stronger of the weak colonies, and if I have queens that are old and useless, I de-

stroy them and introduce my best queen-cells. The addition of the brood to the weaker colonies will prepare them for boxing.

As soon as my old hives are all well-filled with brood, I would continue to hive upon the old stand as before, and divide the brood among the nuclei, which, by this time, will have young laying queens, and if we add brood, we can build them up very fast, and soon prepare them for boxing also, and from these young queens and hives filled with brood, we may expect a fine yield of honey.

As the clover season is just opening, we should look over all hives which have not swarmed, and swarm all which have started queen-cells with eggs in them preparatory to swarming, putting on the sections, and dividing the brood among the nuclei.

After the fruit blossoms have past, I would not put the sections on until the colony had swarmed, or, at least, until the clover season is well advanced, for if we keep the sections off, they will swarm sooner, and I like to get the swarming done up before the height of the clover season.

The Secretary asked Mr. Cook if he was *really sure* that he had ever seen a great advantage to a colony whose brood was "spread" in the spring, over an equally good colony having plenty of honey, but which had been allowed to have its own way with arranging its brood.

Mr. Cook replied that he very decidedly had. The Secretary said that he could not be sure that he ever had, although he had practiced the plan of spreading brood. He had no doubt that uncapping honey in the hive, hastened the production of early brood.

Mr. Root was desired to give his opinion on this matter, and he said, that although we were sometimes apt to be too anxious to hasten bees in the spring, everything must be done that can be done judiciously to get the colonies very strong by the time the harvests comes on.

This was the most important part of bee-keeping. He could winter bees well enough. He did not ask to be able to do it better, but it was a subject of most anxious inquiry to him, how to get his bees strongest as soon as he needed them. The hive must be adapted to this purpose. He did not leave in all the combs, and the hive must be able to be closed up warmly to what was left. Here was the great importance of a correct size and shape of frame. There was a great disadvantage in the long shallow frame, now attempted to be forced upon the bee-keeping public as a standard. The frames must allow the bees to arrange the brood within a spherical cluster.

The cause of the distinguished success of Julius Hoffman, who was one of the most able bee-keepers in the country, was largely due to his frame, his division-boards, and his enameled cloth spread tightly over the tops of the frames. He uses a frame 11 or 12x14 inches, and eight of them in a hive—a grand hive.

A great disadvantage in the old Langstroth hive was, the shallow $\frac{3}{8}$ inch air-chamber over the top of the frames, allowing a circulation of air over the tops of the frames. Bees wintered better in box hives, and we ought to make movable frame hives resemble their good features as far as possible. In the box hive every comb makes a division-board, tightly fitting at the sides and top, so as to allow no circulation of air around or over the bees. To a question, asking if Mr. Hoffman left the enameled cloth on during winters, he answered that he did. He wintered in a very peculiar manner in a depository so warm that the bees hung out over the outside of the hive all the time.

He said, if Prof. Hasbrouck had asked him the same question he put to Mr. Cook, he would have answered, unquestionably he had seen very great benefit from spreading the brood. But it must be done with great care. If the bee-keeper could know certainly just when he would need the bees, there would be little difficulty by manipulating the brood to have just what he wanted on time. If one could see the pile of waxed barrels which he had prepared for buckwheat and fall honey, which were still empty, he would have some idea of the uncertainties of bee-keeping. He said honey ought to be kept in frames to feed in the spring. The capping should be broken, and then the frames should be placed between the brood.

There had been much talk about cheap food for feeding bees. Bee-keepers ought to step on the idea of feeding glucose. The public would get the impression that it was fed to make honey. A good thing about it was, that it does not pay to feed glucose. It does not pay to feed honey back, and he was glad it did not. He next referred to the position of Mr. Cook's paper on natural swarming. He said the box hive was years in advance of natural swarming, and if he used the box hive, he would not allow his bees to swarm naturally. Much was said about the extra energy of natural swarms. This reason of this was, that they had nothing else to do but to store honey. If you accept the motto, "give every hive a good prolific queen," you kill natural swarming.

To a question by Mrs. Thomas, he said, that honey just gathered contained 70 per cent. of water, and that if this was evaporated artificially, it was exactly the same as honey evaporated by the bees in the hive, while the bees were saved much labor. That Mrs. Cotton's feed undergoes no change in the process of its being stored by the bees. If the bees gather molasses, they store molasses. If glucose, they store glucose. It seemed a sad thing to him, when the editor of a bee paper of considerable influence said that "by feeding glucose you obtain honey—not something like honey—it was honey."

Being asked to explain further about his experience in the artificial evaporation of honey, he said that when Mr. Quimby first heard of centrifugal force applied to honey combs, he improvised an extractor imme-

diately, from parts of a fanning mill. At first they had practiced extracting from a small hive, and then letting it stand till it was again filled, and the honey capped. They next tried a large hive with many combs, allowing the bees to spread out the honey, over a large surface, with but little in a cell. They found that in that way they obtained a decided increase of honey. They next concluded that all the bees did to ripen the honey, was to evaporate the water which they noticed would be left hanging to the cover of the hives in large drops. The next step was to prepare an arrangement by which the honey taken from the hive as soon as gathered could be spread out to the air, while it was raised to a high temperature by an oil stove, so that the bees would be saved the great labor which was wearing them out rapidly. He found that he could thus secure a much greater quantity of honey. His machine was much in construction like the evaporators of maple syrup. He keeps the water under it at 75°. He runs it twice over the machine. He has honey thus evaporated which has been kept 2 years without candying.

Dr. Phil, editor of the *Journal of Microscopy*, asked in what way honey evaporated this way was less artificial than maple syrup evaporated in an evaporating pan? Mr. Root replied, that this honey was in no respect different from that ripened in the hive by the bees. Prof. Cook had said that the bees add an acid in ripening the honey, but had finally admitted that ripening was only a process of evaporation of the water contained in the honey. Although he had great respect for the opinion of Dadant & Son, yet he believed that his honey evaporated by his plan was not inferior to any produced by their system.

Mr. Cook asked how he would prevent swarming? He answered that there was no trouble in preventing natural swarms, when bees were run for extracted honey. When taking box honey, his aim is to have all the increase of bees he can in the hives without an increase of colonies, and prevent the desire for swarming. He accomplishes this by removing a card of brood and supplying its place with empty comb or foundation. A good prolific queen, one not already exhausted by laying, is a preventive of swarming. No system of practice in taking box honey will prevent swarming. He was glad that Mr. Cook advised allowing natural swarming at first to obtain queen-cells.

Mrs. Thomas, in speaking of the paper, said she never put on surplus boxes till the hive was filled with honey. Swarming comes to bees as blossoms to flowers. In contracting brood-nest in the spring, she used division-boards of card-boards, cut by machinery to fit the inside of the hive closely.

Mr. Hutchinson said that allowance must be made in adopting the practice of others, for the difference of locality, which was illustrated by the fact that the canal near Mr. Root opened May 10, while the one near himself opened on March 20.

The next paper was then read by the Secretary, on

HANDLING BEES.

This term is significant of the difference between the old bee-keeping and the new. Formerly there was no such thing as handling bees while alive, except to set them over the brimstone pit, but with the introduction of movable combs, bees have been "handled" and "handled," and often handled to death. I think I am safe in saying that "handling bees" is, in itself, always a detriment to them—more or less—and that a hive of bees should never be opened unless there be a positive necessity either to learn its condition, or to perform some operation which, in its effect, will benefit them more than the handling will do them injury, or to take away the surplus for which they are kept. Moreover, handling bees takes time and labor, and the bee-keeper must economize these by spending none which necessity does not demand.

From considerations of this economy of labor, if for no other reason, I would prefer natural swarming to any system of artificial increase. I am not a believer with Mr. House, in his part of "Alley's Handy Book," that a bee-keeper must be able to tell the condition of every colony from the outside appearance. I must confess that after a pretty extensive experience, my opinion passed in that way would be about as valuable as my estimate of the quantity of money in a trunk, by looking at the cover.

While I believe a man must look inside to see how it is with a colony, yet any man who is out for a bee-keeper must be able to tell by a rapid examination in the spring, accurately the condition of every colony then, and what help each needs, and afterwards by means of his record he must be able to judge just when and what kind of attention each colony will again need, and, except for that, I consider it necessary for their greatest prosperity, that they be left absolutely alone. It is a fortunate era for the bees of a beginner, when he gets so many colonies, that he is not able "to go through them" every few days for some imaginary purpose.

Admitting that it is necessary that a colony of bees should be over-hauled sometimes, let us consider the wholesome restrictions and limitations of this operation. First, I should say that bees ought not to be opened in cold and disagreeable weather. I am convinced that disturbance at such times, is one cause of that most annoying of accidents to a colony, the balling and killing of a queen by her own subjects. Several years ago a gentleman came to me one cold disagreeable day in April to get me to go and look at his bees, which he wanted to sell. He opened seven hives to show them. In just a week we had about agreed on the price, and I went to look them over to see that they were yet all right. Six out of the seven colonies had queen-cells which they had just begun to cap, showing that the queen had been killed on the

day of the previous examination. Again, early last spring, a gentleman called upon me on much the same kind of a day to get a queen. I opened colony after colony, at least five or six, and every time found the bees balling the queen. These are a couple of a great many instances which I could give, where I have found queens balled when the only explanation I could give was disturbance in bad weather. Mr. Doolittle has lately said that in exposing brood in cold weather, it is very easily chilled, so that the bees remove it. I have never observed the fact, but can readily believe that it is the case.

2. At times when bees are not getting honey rapidly, they should not be opened in the middle of the day, which is the time usually recommended by the books for working with bees. As soon as the frames of a colony are exposed at such times, a number of bees, industriously foraging around to find honest work, are attracted by the smell of honey. The smoke of the operator helps them to gain an entrance into the open hive, and a taste of the coveted sweets, and the mischief begins. Constantly increasing crowds follow him around, and force themselves recklessly into every hive he opens, exciting the bees with which he is working to fury in stinging, and going themselves to almost certain death. The whole yard is soon in an uproar, and a battle is begun which continues, at least, for the remainder of the day, and whose victims lay in piles of thousands at every entrance, and often include queens as well as subjects. I suppose, at such times, a movable tent is a kind of protection against robbing, but I regard it as an encumbrance which is perfectly useless, if a little care is observed to leave all necessary manipulations to the proper times of the day. The evening, I consider the proper time, *par excellence*, for handling bees. They are strict believers in the old adage, "Early to bed and early to rise." When the sun is yet a half-hour high they begin to knock off work and gather quietly at home, and it must be something extraordinary which will tempt them away much after this time, unless they are educated to bad habits. Home seems to have a soothing effect upon them as well as upon the human species. Now is the time to do with them what is necessary to be done, and by lively work, everything necessary in seasons of robbing, even in a large apiary, and even where queen-rearing is made an extensive speciality, can easily be done. Of course there would not be time in a large apiary, for putting on boxes and taking of surplus and extracting, but such work is done only when honey is coming in, when one can work at any time of day, without danger from robbers.

It is surprising to one who has never tried it, with what ease and success, queens of all kinds, virgin as well as fertile, can be smoked into the entrances of hives at twilight. Bees are not on the lookout for strangers at this time of day, and they are ready to accept anything put into their

hives, especially as the smell of all is made alike with a little smoke. I have not caged a queen of any kind for the last two years, and I have scarcely lost one in this time in introducing, and I have not found it necessary to use tobacco smoke either, as Mr. Alley recommends.

Bees may also be handled in seasons of robbers, early in the morning. There are few times in the summer when a little honey is not found early in the morning, enough to take the attention of the bees, and keep them away from the bee-master long enough for him to do what he cannot find time to do in the evening.

3. All necessary handling of bees must be done with the utmost rapidity, and with just a little disturbance of the arrangements of the bees as possible. To this end, all racks and boxes should be easily adjusted, so that in removing surplus, the bees may be exposed as little, and for as short a time, as possible. If a hive is kept open for a long time, while complicated gimcracks are torn apart and fitted together again, robbing is apt to be induced even in seasons of the best honey flow, and the workers soon find out that their attention is wanted at home, to protect their stores, and to re-establish the destroyed order of the hive, even if the demoralization is not communicated to all other colonies, and a consequent serious loss of honey is the result.

So any extensive manning of a large colony of bees for so little reason as, perhaps, to find a hybrid queen to put a pure one in its place, should be carefully avoided.

I have been in the habit, for a long time, if any of my neighbors come to me to get some bees, just to raise honey for their own use, to recommend them to keep them in a box hive, and to "take them up" in the fall, believing they will get more honey in this way than if their bees were mauled over every little while, as beginners are very apt to do. If the above precautions in handling bees come to be generally heeded, I would begin to feel that the movable-comb hive is a safe thing in the hands of beginners, but not till then.

Mr. Cook thought but few colonies could be kept by one man, if all the handling was to be done only in the evening.

The secretary replied that when honey was coming in, bees could be handled easily at any time in the day, but in a time of honey dearth, there should be need, even in a large apiary, of no more handling that could be done in the evening.

Mr. Root thought that an impression might go abroad from the paper, that would be undesirable. There were many now keeping bees in box hives, who were afraid to have their bees transferred, fearing injury to them, and it would be unfortunate to have them confirmed, in such opinion. The fact is, it is worth \$1 to a colony to be transferred. It would generally pay to drive bees out of a hive, and wash and scald it, and paint full the cracks, sometimes, to get rid of the parasites which were apt to trouble bees. He

had even known them to lurk in the grain of the wood, so minute were some of them.

Mr. Hahman transfers and prevents any trouble from robbing by closing other hives.

Prof. Kroeh had had great trouble the past season in introducing queens. He would like to hear Mr. Root's opinion on the subject.

Mr. Root said he was the most successful in introducing without a cage. He knew in an instant when a queen would be killed, but could not tell how. He thinks queens are killed, if at all, the instant they touch the combs. There is not much trouble if bees are well-filled with honey. He shakes the bees all out and then puts the new queen with them, and lets them run in.

Mr. Hutelinson said he introduces queens by Mr. Moore's plan, with a round cage. He places it between the combs, with corks, for 36 hours. He then takes the cork from one end and closes it with paper covered with honey. In a short time the bees eat through the paper and liberate the queen.

Mrs. Thomas objected to that method being called by the name of Mr. Moore, or any other man. She had used that method for 18 years, and never heard it called by any one's name. She never introduces queens to full colonies.

Prof. Kroeh preferred to introduce queens to brood, by putting the queen on a frame of brood, and then putting that frame into a wire-cloth box, and then into the hive. After a few days, when a quantity of brood was hatched out with the queen, let them out to the other bees. He had succeeded once when he did not expect to, by lifting a frame of bees with the queen from a nucleus and putting it into the middle of a queenless colony.

Mr. Cumkey had introduced a great many queens, and had come to the conclusion that the less trouble taken to do it, the better. He always used the Betsinger method, and was generally successful.

Mr. Hahman had visited Mr. Root, at Medina, Ohio, and had seen the man who introduces queens there do it, as if the bees had got educated to receive strange queens.

Mr. Root said, he did not like any method by which the bees liberated the queen. He wanted to see how the bees received her when they first had access to her. He had never seen any reason for thinking that it was dangerous to examine bees soon after a queen was introduced.

Prof. Kroeh asked Mr. Root what "balling" meant.

He answered that there was something very mysterious about it. He did not know the cause, but could easily tell a queen which had been balled. They have a smooth, shining appearance, and were worthless.

To a question as to whether he extracted from the brood nest, he answered, that he had no hesitation in extracting from combs with unsealed brood in them. He had seen brood started from the bottom of the cells by extracting, but he always found that

it was soon put into place again by the bees. There was a loss sometimes in extracting, as the bees were disturbed, so that they did not go to the fields for the remainder of the day, while other colonies standing on the scales were gaining 4 or 5 lbs. per hour.

The President said that his daughter who managed his apiary, had developed a method of introducing queens which was very satisfactory. She lifts a frame of brood out of the hive and puts the queen on it—puts it into a nucleus box for a couple of days. She then returns it to the rear of the hive (which is a Simplicity) with the combs running crosswise, and puts it behind a division board which does not reach quite to the bottom.

The Secretary said that he had only alluded in his paper to introducing queens. His method was this: At twilight, after the bees had stopped flying, he put the queen on the alighting board of the hive, and let her run in; at the same time smoking the bees briskly. He had even introduced virgin queens to full colonies, and queens to colonies with fertile workers, and he always put them in, with perfect faith that they would be all right, and had never lost one by that method. He used to be enthusiastic over the Betsinger cage, but the "twilight" plan was much superior.

Mr. Root said he would be afraid to risk it.

Mrs. Thomas asked if any one knew of a successful method of out-door wintering without chaff hives. This fall she had boxes made to put over her hives, and had packed them with leaves, and she wished to have the opinion of the Convention as to its safety. She had got the idea from a florist, who advised a similar method for covering half-hardy plants. She always laid over the frames of every colony a stick of rock candy. She considered it of the greatest importance.

President Thompson said that was the method he always used for wintering. He had permanent boxes around each hive, which were packed with chaff or a similar non-conductor, and then covered by a single pitch roof. There was no cover to his hives. He found the packing as useful in summer as in winter.

The President then announced the special committee to confer with the managers of Fairs. Mr. J. H. M. Cook, Mr. Hutchinson and Prof. Hasbrouck, to which was subsequently added, by resolution, the President himself.

The Treasurer was then directed, by resolution, to have 120 postal cards printed with the notice of the next meeting, one to be sent by the Secretary to each member.

It was resolved that the executive committee prepare a programme of the next meeting, at least a month previous, and that this be published with notices of the meeting.

A vote of thanks was extended to the visiting delegates from the Philadelphia Bee-Keepers' Association for their attendance and participation in this meeting, also to Mr. L. C. Root

for valuable assistance in the discussion.

It was then moved and adopted that the Society hold its next meeting for two days, on the second Wednesday and Thursday of March next, to which time the meeting was adjourned.

For the American Bee Journal.

I'll Never Mind what they Say.

J. M. HICKS.

I shall not worry or fret,
About what people think
Of my ways or my means—
Of my food or my drink,
If I know I am doing
My best every day—
With the right on my side,
I'll never mind what they say.

I'll lay out in the morning
My plans for each hour,
And I'll never forget
That old Time is a power.
This will I also remember,
Among truths old and new,
The world is too busy
To think of me and of you.

Then I'll garner the minutes,
That make up the hours,
And in my pilgrimage
I'll pluck in the flowers;
Should grumblers assure me,
My course will not pay,
With my conscience at rest
I'll not mind what they say.

Then let me forget, as I should,
The insensate drong,
That jostles me daily
While I'm marching along;
I'll press onward and upward,
I'll make no delay,
And though the people talk
I'll not mind what they say.

I shall trust in His cause,
And hope for the best,
Knowing, as I well do,
God is holy and just;
He gave us good laws
Which, if we understand,
We shall gather the sweets
He placed at our command.

Then we will guard and protect,
The good honey bee,
He so bountifully provided
For you and for me,
With the right on my side,
I'll not mind what they say,
But pluck in the flowers,
And make no delay.

My Experience with Bees.

WM. H. WESTON.

Last year, in my ignorance, I bought what I supposed was a colony of bees, but what I would now call a two-frame nucleus. Of course they did not live through the winter, although I fed them plenty, I having bought them late in the summer, and being put into my hive, they had nothing to start on; so, last spring, I had the hive with some empty comb with which to start the year.

As we had such a late spring, I did not buy any until May. I then bought a colony of common bees in an old hive, and transferred them on the 24th into the hive I prefer, and which, I think, is the best for this climate; I refer to the D. A. Jones hive. We then had cold, wet weather until the latter part of June; the bees gathering but very little, only enough to keep up breeding. About June 20, I divided and introduced an Italian queen to one of them. Shortly after that we had splendid weather for

gathering honey, and the bees appeared to realize the fact, by working to their fullest extent, and it being my first year, I had not enough experience to know how much honey a colony could gather, so I was not prepared for such a flow. They filled the hives full, and as I had not an extractor, I had to put in empty frames to keep them going until I could hire one. I had previously bought some comb foundation with which I filled the frames that I replaced the full ones with; so, of course, I was not so badly off, after all.

About the latter part of July, one of the colonies swarmed while I was away from home. As soon as I arrived, my wife informed me of the fact, and as it was my first attempt at hiving a swarm, I have no doubt I was very awkward about it, but I succeeded very well, although I had never seen any person do it. They had swarmed on the trunk of a small shade tree. At last I got them hived, but not knowing whether I had secured the queen, and wanting to be sure about it, I gave them a frame or two of brood from my Italian colony. In a day or two I found out that the queen was in the new hive all right, and was laying first rate. So I will winter 3 colonies, I think, as they are all strong and have plenty of stores to winter them. I have taken out all the frames, leaving five for each hive, which will crowd them up pretty well. I have packed the hive on the inside.

I secured from the one colony and its increase over 100 lbs. of honey, besides some that we used in the house. The most of it was extracted; part in one-pound sections, and the balance in frames, which I will feed to them in the spring. I think I have not done so badly, for my first year, with the small amount of time I had to spare.

London, Ont., Nov. 19, 1883.

Ohio State Convention.

The Ohio bee-keepers will hold their annual convention in Columbus, O., Jan. 14, 15 and 16, 1884. All interested in bee-culture are invited. The following subjects will be discussed: "How to winter bees successfully." "Are the new races of bees a success?" "What can we do to prevent adulteration of honey?" "How to create a home market for honey." "How many colonies can be kept in one locality?" "Can we do without separators?" "Which are best, deep or shallow frames?" "What shall we do with second swarms?" "How many brood frames are necessary in a hive?" "Which is the most salable section, one-half, one or two pounds?" "Is it advisable for all bee-keepers to adopt a standard size of frame?" "What is the most desirable width of sections?"

The above questions will be discussed by eminent men, such as Rev. L. L. Langstroth, Dr. Besse, S. D. Riegel and others, and in addition to the above, Prof. Lizenby, of the Ohio University, will deliver a lecture on "Honey-producing plants." Also Mrs. Jennie Culp will read an essay.

C. M. KINGSBURY, Sec.

For the American Bee Journal.

Size and Style of Frame, etc.

G. M. DOOLITTLE.

On page 563 of the BEE JOURNAL, I find these words: "I wish to ask Mr. Doolittle what style of frame, how placed, what size, one or two stories, would he adopt if starting anew into bee-keeping, for extracted and comb honey?" In answering the above, I could simply give my preference as to frames, how used, etc., but as this would only prove to the reader that Doolittle used such and such frames and hives, without reasons for so doing, I prefer to tell why I would and *do* adopt the style of frame and hive I use both for comb and extracted honey. This being done, the reader can compare my reasons with those of others using different styles of frames and hives than I do, and thus, after comparison, come to a definite conclusion as to what they will adopt. Mere assertions never help any one to a correct decision on any matter, but reasons are always helpful.

When I first began bee-keeping, I used the Langstroth frame, that being $17\frac{3}{8} \times 9\frac{1}{2}$. For the reason that my father had been more successful, years before, in producing comb honey while using box hives, when he placed his boxes at the sides of the hive in connection with top boxes, I desired to adopt the plan of both side and top boxing in connection with frame hives. That the above style of frame would not admit of this plan of working to the best advantage, was one reason why I dispensed with it and adopted another. However, even with the Langstroth frame, I was more successful in producing honey on the above plan than I was on the tiering up plan, recommended by many. Next I worked with the American frame, which was at that time (if I recollect aright) 12×14 inches, as used about here. This did not prove better than the Langstroth frame, for while the Langstroth hive gave the largest returns from the top boxes, the American gave the most at the sides.

To avoid these to extremes, I next tried the Gallup style of frame, which is $10\frac{3}{4} \times 10\frac{3}{4}$, inside measure. With this I found the bees would work in about equal proportions in both side and top boxes, and by adopting the single case system when section boxes came into use, and raising the part filled with sections (by the case) from the sides, and placing them on the top as full cases were removed, I found I could get an average yield of one-third more honey than by any method I had heretofore used.

Then, again, I reduced the size of the brood-chamber to $\frac{2}{3}$ the size recommended by Mr. Gallup, thus getting the brood in compact form, and close to the sections on both sides and top. The reason why the Langstroth frame is best adapted to top boxing, is because the brood comes nearer to the top than the sides, as a rule, and for the reason that the brood is at the

sides when the American frame is used, is why that is best adapted to side storing. The using of so few frames in the brood-chamber, that they shall be literally filled with brood, and then surrounding this brood with sections, is one of the great secrets of success as applied to comb honey, in my opinion.

During the past season I worked some hives with only 6 Gallup frames, instead of 9 as formerly used, or 12 as recommended by Mr. Gallup; and met with a success never before attained by me in the production of comb honey. If these colonies so worked, prove equal to wintering, I shall adopt the plan quite largely in the future. That the Gallup frame allows of being successfully worked on the above plan, and that the above plan is the one looking toward the greatest success, is my reason for using it, and the reason why I should adopt it, if I were starting anew into bee-keeping. Some will say that the tiering up plan will distance the above, as to labor required, by a long ways. Admitted, but which is considered the better farmer, the man who employs certain help to work 200 acres of land to secure a certain yield therefrom, or the man who uses the same help on 100 acres, and secures as large, if not a larger amount than does the other from his 200 acres. The greatest number of colonies kept should not be our ambition, but the largest yield possible from a given number. As in the above, our 200-acre farmer has double the capital invested on which he is getting only the same returns as the other with 100 acres, so if we secure the amount it would take to keep 100 colonies of bees for a year as a surplus, where only 50 are kept, we get the honey from our field in shape of surplus instead of feed for the bees, thus making a gain in our favor. As it takes at least 60 pounds of honey to keep one colony of bees for one year, this item is worth looking after.

But I have digressed. I am asked how the frames are placed. I have them run from front to rear of the hive, or endwise to the entrance, for where side boxes are used, the bees would have to travel under or through the boxes to get from the entrance to the brood-chamber.

For comb honey I use a cap or chamber to the hive 8 inches high, so as to cover the top boxes, and also to admit of chaff or sawdust packing for winter. So far I have only spoken of my preference for the Gallup frame as regards comb honey. I have equally good reasons for my adopting it for the formation of nuclei, queen-rearing, wintering, etc., etc., but time and space forbid my giving them at this time.

For extracting, I am as well pleased with the Gallup frame as with any other, and as I use it for comb honey, of course I prefer it for extracting. Were I working for extracted honey exclusively, I should not consider its advantages as great as I do for comb honey. That it can hang in the extractor the same as in the hive, is one reason for preferring it, and that the

Langstroth frame cannot so hang in the extractor, is an objection to it, in my opinion.

In extracting, I use two different plans, one of which is to use the hive two and three stories high, leaving the combs undisturbed until the honey season is over. The other is to place combs in the side storing apartments of my comb honey hive, and extract from them as fast as filled, ripening the honey in a warm room, in open-mouthed vessels. Each plan has its advantages and disadvantages. By the former I get a splendid article of honey with a little labor. By the latter I get nearly double the quantity, but it requires more labor, at a time labor is of the greatest value, and the quality of the honey is not nearly as good. If this reply is not satisfactory in all points to Mr. Molesworth, he will please call again, and I will try and make it so.

Borodino, N. Y.

The Michigan Convention.

DEAR MR. EDITOR:—May I ask you to call special attention to our next annual meeting to be held in Flint, Dec. 5 and 6, of the Michigan Bee-keepers' Association. We expect to have by far the best meeting ever held in the State. It is expected that the Rev. L. L. Langstroth will be present. To see and hear him will pay any one for the trouble and expense incident to the journey. We also expect D. A. Jones, A. I. Root, C. F. Muth, and hope to have C. C. Miller and T. G. Newman. From what I hear, Michigan bee-keepers are to be out in force. Hotel rates are to be \$1.00 a day. Further particulars as to programme, will be given soon. We expect to get reduced rates on the railroads. To aid in this, and that I may know how many certificates on railroads to ask for, will every one in this or other States who expect to come, drop me a card at once to that effect?

A. J. COOK, President.

[Sorry we cannot attend.—ED.]

The annual meeting of the Lorain County Bee-keepers' Association will be held in the Court House at Elyria, Dec. 19, 1883.

O. J. TERRELL, Sec.

North Ridgeville, O.

Owing to the death of our Secretary, Mr. T. Brookins, please announce in the BEE JOURNAL that the annual meeting of the Champlain Valley Bee-keepers' Association, will meet in the parlors of the Addison House, Middleburg, Vt., the second Thursday in January, 1884.

J. E. CRANE, Pres.

A meeting of the bee-keepers of Des Moines Co., Iowa, will be held on the second Tuesday in January, at 10 a. m., for the purpose of organizing a county bee-keepers' association, at Middleton, Iowa, in R. C. Crawford's Hall. JOHN NAU, FRANK MELCHER, A. M. BALDWIN, W. R. GLANDON, Committee.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Extracted Honey Production.

Mr. James Heddon: Please describe your $\frac{1}{2}$ -story box for extracted honey, in the BEE JOURNAL. How wide inside, how big, etc.

2. Is it necessary to glue sections?

3. Is glassed honey more preferable than tin boxes for retailing extracted honey in?

4. Is there any danger of loaf or granulated sugar being adulterated, and is the former any better for winter food for bees than the latter?

Sutton, N. H. F. M. CHENEY.

ANSWERS.—To produce extracted honey for sweet sauce, it should be well ripened, capped over before extracted, and I prefer to store it in $\frac{1}{2}$ story frames, otherwise the same size of the hive below, and upon the tiering-up system.

2. Not at all, if they are decently made.

3. I have never seen honey on the market in tin receptacles, where it could compete with that stored in glass; though tin is most advantageous to the producer, consumers do not like it.

4. Sugar agents tell me that granulated sugar has been adulterated with grape sugar, but that there are refineries that can be relied upon for the pure article. I have little fears, and see no difference between loaf and granulated, though loaf is usually considered a little more refined.

Why use a Honey-Board?

Will Mr. Heddon please answer, through the BEE JOURNAL, why he uses the skeleton honey-board at all? If the right bee space is observed between the brood frames and the bottom of the case, is this second space not worse than useless?

C. H. DIBBERN.

Milan, Ill., Nov. 33, 1883.

ANSWER.—The objections to the use of my honey-board are three: cost, manipulation, and storage when out of use. The advantages are: there are less bees in the way when adjusting and removing supers, less opportunity for robbers to get in their work at that time, the sections are much cleaner and freer from bits of comb, and when taken from the hive are never dripping from broken cells which have been built between them and the brood frames. It makes the queen less liable to go above to lay, economizes wax, by preventing these

brace combs. When one case is raised up and another one put under, no braces are lifted with the under sections, to be finished out and attached to the tops of those just put in their place. This bracing will not take place between sections and each other, but between the lower sections and brood frames, if the honey-board is not used; hence, only one honey-board is needed to each hive, and does not have to be moved through all the manipulations of the supers, only when we work in the brood-chamber, when it is as easily removed as a cover.

The honey-board has 9 slats, with $\frac{3}{8}$ spaces between them; the centre of each slat comes directly over the space between the brood-frames below, and the centre of each top-bar below is directly under the slots of the honey-board. The outer edges of the honey-board are bee-space higher than the top surface of the slats which forms the second space. You see that the supers of sections fit the hive perfectly without any honey-board, and the same with. You also see by what method we cut off this building of brace combs, and at the same time give perfect egress to the heat, odor and bees.

After careful experiment of no small dimensions, I can say that this honey-board is no hindrance whatever to the bees entering the sections. With an upper set of combs for the extractor, it is well-nigh a necessity, and in either case worth many times its cost and trouble.

Section Racks & Double-Walled Hives.

I wish those who speak of their honey racks, would describe them in detail, or else advertise them for sale, so that we could get them, or at least a sample for trial. I would also like to know which is the best way to manage bees in the spring to get the most comb honey? Is it to make them swarm early, and be ready for white clover? or, to undertake to stop them from swarming until white clover is over, which was the first of July, this year, and then divide them? I have 8 colonies now, and I wish to double them next year, if they winter all right, which they will do on the summer stands. I would like to know if Mr. Heddon will tell us why he objects to double-walled hives, as we contemplate making ours double, more particularly to keep them cool in summer than to keep them warm in winter, as our winters are not very cold, hardly ever below 10 degrees above zero.

S. M. HICKEN.

Delaware City, Del., Nov. 26, 1883.

ANSWER.—How to manage bees in spring to get the most comb honey,

though a short question, would demand too long an article for this department. I will write on that, some future time. Regarding double-wall hives, they can be no cooler, nor as cool in summer, as single-wall hives, shaded with a board. This is plainly seen when once thought of.

SELECTIONS FROM OUR LETTER BOX

Bees Prepared for Winter.

Bees are in very good condition this fall. One is almost lost to know what to do, as everybody seems to have a different way of wintering bees. In Simplicity hives, I turn over the bottom boards, fill with sawdust, give six good frames of honey, a division-board on each side, the upper story full of chaff, build a sort of straw-stack over the whole, and give them a good "letting alone" till spring returns.

C. WECKESER.

Marshallville, O., Nov. 20, 1883.

Honey Crop in Mississippi.

I am moving my apiary of 300 colonies 15 miles, and find it quite a job. It has been a poor honey season here, this year. 21,500 pounds from 172 colonies, spring count; part comb and part extracted. The worst that I have ever had in this country.

G. C. VAUGHT.

Greenville, Miss., Nov. 16, 1883.

My Syrian Bees.

Reading, in the instructive article on page 592 of the BEE JOURNAL, by L. C. Johnson, entitled "The Improvement of Bees," whose experience with the Syrian bees and queens is so near like my own, I will give it to the readers of the indispensable BEE JOURNAL. On the 1st of July, 1883, I received a Syrian queen of Mr. Henderson, of Tennessee. She was immediately introduced into a very light colony of Hybrids, by the smoking method. I never saw bees multiply so fast. As I did not wish to let them swarm, upon the first appearance of queen cells, I removed 4 full Langstroth frames of brood; but this only checked them for a few days. Soon after, and while I was entertaining company, I saw the Syrians in the air, and, as they did not cluster soon enough to suit me, I took a pail of water and threw some on them with a cup as they they were circling in the air, and they soon returned to the hive. I then watched them for a couple of hours, until I had time to attend to them. I proceeded to divide them, and found two frames with at least 40 queen cells. I then cut out the cells, and laid them down on the cap of the hive; before I had done I saw one emerge from the cell and fly out of sight, but it soon returned to the place it started from. I soon missed another, which was gone

several minutes. I then took the most of the brood, with the old queen and bees, and removed them several feet from the old stand, depending on one of the young queens, and returning bees, to make a colony at the old stand, but the old queen was bound to go, and go she did with a swarm to the woods, when no one saw them. Those remaining built another batch of queen cells, replaced their queen and built up to a fair colony, without help, except a little feeding, and I think will be as likely to winter as well as any I have. I would say in their praise, they are beautiful three-banded bees, smaller than the Italian and quicker in their movements. I have handled them many times without smoke, and think them the gentlest bees I have yet found; I never was stung by one yet. S. J. YOUNGMAN.

Cato, Mich., Nov. 25, 1883.

Inseparable Cyprians.

I have 57 colonies of bees in good condition. I have done well with them during the past season, although it could not be called a good honey season in this section. I have the Cyprian, Italian, German, and Syrian bees. Deliver me from the Cyprians; when disturbed, they fight everything in reach of them. Last summer they attacked a horse hitched to a fence a hundred yards distant, and would have killed it had I not been close by. At another time they attacked a tree standing close by; they covered it by thousands; but I could not see that the tree sustained much damage. I find them very prolific, and want to swarm all the time, when they ought to be laying up honey; but I find the hives all full of honey in the fall of the year. In the spring I expect to move my bees out into the country 3 miles from town, and half a mile from any house or public road, and Italianize my apiary as fast as possible. I expect to devote my whole time to my bees hereafter. I find that it pays, if only attended to.

NATHAN M. WOODMAN.

Bushnell, Ill., Nov. 26, 1883.

Give a Frame of Brood to Swarms.

On page 592, Mr. W. H. Stewart says: "If any one has lost a swarm of bees that were hived on full sheets of foundation, let us hear from him." I will answer to that call. Sometime during the month of June, 1881, I transferred a colony of black bees from a box to a Langstroth hive on a full set of full sheets of foundation, and, as there were moths in the box hive, I did not move any of the old combs. As there was a good honey flow at the time, I considered this the same as a new swarm. The first time I hived them they remained only 24 hours, when out they came and clustered in a tree. I examined the hive and found the foundation partly drawn out, and the queen had deposited eggs in it. I again hived them, and they came out again in 24 hours. This time I clipped the queen's wings and returned them, and on the next day they came out again, but, as the queen could not fly, this time she fell in the

grass, and the bees came back and clustered outside of the hive. I then gave them a frame of brood, and all went well. What then was the cause of the bees absconding, if not for the want of brood? In this case the foundation did not keep them from leaving the new hive, and they were only quieted by giving them a frame of brood.

J. G. NORTON.

Macomb, Ill., Nov. 28, 1883.

My Report for this Year.

I had, in the fall of 1882, 27 colonies. I wintered them all on the summer stands, and had 27 last spring to begin with. They increased to 47, by natural swarming; I sold 3 and have 44 now, with plenty of white clover honey in the hives to winter on, but I only got an average of 27½ lbs. of honey to the colony, spring count; it was nearly all white clover honey in 1 and 2 lb. sections, as nice as I ever saw. There was a very heavy crop of white clover, and it lasted longer than usual, but while it was in bloom, the season was so wet and cold that the bees were kept in too much to make much headway, but when there did come a little sunshine, they made use of it. When the clover bloom was gone, the honey season was over; from that on until frost, it was so dry that the bees merely gathered enough for the time being, so that they did not have to fall back on their stores, and, as I did not extract any, that accounts for my bees having white clover honey to winter on. I may be too much of "an old fogey," but I do not believe in taking the honey all away from them and giving them something else to winter on.

JACOB COPELAND.

Allendale, Ills., Nov. 22, 1883.

Damage by a Storm.

The storm at Peotone, Ill., on Tuesday night, Nov. 20, split in two my 60 feet barn, killing 5 cows, 3 calves, 2 sheep and one fat hog, besides blowing over half a mile of board fence. My best colony, and 48 colonies of bees on the summer stands, are all safe.

C. SCHRIER.

Peotone, Ill., Nov. 30, 1883.

How I Winter my Bees.

I have 80 colonies of bees in the cellar and 3 outside. My frames are 13½ x 9½ inches outside and run crosswise; 13 frames to the hive. When the honey season is over, I make a box 12x14½ inside to hold 8 of my frames which I select for winter. This box will sit inside the hive, making it a complete summer and winter hive. Those wintered in the cellar have the outside box left on the summer stands, except the bottoms. I put a ¾ inch stick under each corner of the hives to give air, or rather to keep them dry. I have a cushion on top for out-doors. I make the tops as tight as possible, and fill in around with flax-tow. My cellar is not very dry, but is well ventilated by a pipe connected with my kitchen stove, and an air tube of 4-inch tile running 20 feet underground. I have wintered my bees in this way

without loss for 3 years. I put the bees in on Nov. 13 and 14, and to-day they are quiet with temperature at 42 to 45 degrees F. I have no fear of losing any. With the three outside, I am testing what the bees can stand with open doors and closed tops on deep frames.

A. WICKERTS.

Matteson, Ill., Nov. 18, 1883.

Prepared for Winter.

The work in the apiary is done once more, and my bees are packed and prepared again for the winter. Last spring I commenced the season with 32 colonies. The spring was cold and wet, and bees did not get enough to carry on breeding, so they had to be fed some. On June 10, white clover bloomed, but yielded less than half a crop of honey. Basswood opened on July 15, and gave a very good yield of honey, but there is very little of it here. With the help of sweet clover, I obtained 300 pounds of comb honey, and 650 pounds of extracted. The comb honey is sold for 20 cents a pound, and the extracted for 12½ cts. 200 pounds of honey I set aside for family use and feeding next spring. The bees increased to 52 colonies. Bees are in good condition for winter.

WM. BOLLING.

Dunkirk, N. Y., Nov. 29, 1883.

Bee-Keeping in the Indian Territory.

Never hearing anything from this country, I will write a few lines to let the world know that we keep bees too, but it has been a bad year for bees in the Southern part of this Territory and Texas. The spring was so cool and backward that they swarmed but little, and the balance of the season was very poor for honey. I bought several colonies, an extractor, and six Italian queens; made new hives and transferred the bees. I use the Mitchell hive, single story, for extracted honey. They paid expenses, and I realized a little on them. I will run about 50 colonies for extracted honey next year. I have a ready home market at 15 cents for all my honey. We had our first killing frost on the 14th of this month, but it did not kill all of the flowers. My Italians and hybrids are gathering a little honey and pollen to-day, from a little white blossom that grows on the creeks, in the woods. It is warm and pleasant to-day; we have had but two frosts this season.

G. P. GRINSTEAD.

Oakland, Ind. Ter., Nov. 20, 1883.

The Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association, will hold its annual meeting in Temperance Hall, Freeport, Ill., on Jan. 15 and 16, 1884.

J. STEWART, Sec.

Rock City, Ill., Nov. 30, 1883.

The 5th annual Convention of the Northeastern Ohio and Northwestern Pennsylvania Bee-Keepers' Association, will be held at Jefferson, Ohio, Jan. 16 and 17, 1884. All are cordially invited.

C. H. COON, Sec.

New Lyme, O., Nov. 26, 1883.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Make all Postal Money Orders and Postal Notes payable at the Madison St. Station, Chicago, Ill.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper, shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter, on your label, notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a *continual* statement of account.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

Our New List of Premiums.

Getting up Clubs for 1884.

To increase the number of readers of the BEE JOURNAL, we believe, will aid progressive bee-culture and help to elevate the pursuit. We, therefore, offer the following premiums for getting up clubs:

While no subscription to the BEE JOURNAL will be taken for less than the regular advertised prices (viz.: Weekly, \$2.00; Monthly, \$1.00),—any one getting up a club of two copies, or more, may select from "OUR BOOK LIST" anything therein named, to the amount of 15 cents for every dollar they send *direct to this office*, to pay them for the trouble of getting up the club; and these books will be sent, postpaid, to any address desired.

For a club of 3 Weekly or 6 Monthly and \$6.00, we will make an *additional* present of a Pocket Dictionary, bound in cloth, containing 320 pages.

For a club of 5 Weekly or 10 Monthly, (or a mixed club of both,) with \$10, we will, in addition to the 15 per cent, present a copy of the AMERICAN "POPULAR" DICTIONARY, comprising every word in the English language that enters into speech or writing; it contains 32,000 words and phrases, 670 illustrations and 512 pages; it is nicely bound in cloth, and will be sent by mail, postpaid, to any address desired.

For a club of \$20, for 10 Weeklies, or an equivalent in Monthlies, we will present, besides the 15 per cent. in books, a tested Italian queen, by mail, postpaid.

Subscriptions for two or more years for one person, will count the same as each year for a different person.

For a club of 100 Weekly (or its equivalent in Monthlies), with \$200, we will send a Magnificent Organ worth \$150. See description on page 614 of the Weekly for Nov. 28, 1883.

Do not let your numbers of the BEE JOURNAL for 1883 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

It must be understood that, should an advertiser desire to cancel an unexpired contract, he can do so only by paying regular rates for the number of insertions his advertisement has had.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

Bee Pasturage a Necessity.—We have issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for ten cents.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents. for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Sample Copies of the AMERICAN BEE JOURNAL will be sent *free* to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

Articles for publication must be written on a separate piece of paper from items of business.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

Speak a word for the BEE JOURNAL to neighbors who keep bees, and send on at least one new subscription with your own? Our premium, "Bees and Honey," in cloth, for one new subscriber to the Weekly, or two for the Monthly, besides your own subscription to either edition, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

We need the numbers of the BEE JOURNAL for August, 1866, and April, 1876. Any one having them to spare, are requested to send us a Postal Card. We will give 25 cents for each. Do not send them without writing, for we want only one of each; and, if we are not already supplied, we will take them.

Advertisers' Opinion.

The queen business is *rushing*, and we think the BEE JOURNAL deserves much credit as an advertising medium.

THE AMERICAN BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

Prepare for the Fairs.

The article on page 643, by the Rev. O. Clute, is very timely, for the usual January meetings of the Executive Committees of Fairs will soon be here.

Public manipulations with bees and magnificent honey exhibits will soon become the most attractive features of State, County, and District Fairs. There are good many reasons for introducing such, but the chief one, perhaps, is that those who produce honey for the market may be induced to present it in the most marketable shape; for the new methods and new ideas of practical management must take the place of the old and undesirable ones.

We respectfully suggest to all who have the management of fairs, that a day be set apart during the season for public manipulations and explanations on this subject, and soon these *industrial days* will become as popular and attractive to the public as are now the "speed days" of horses, or the "trial days" of reapers and plows.

Bee-keeping should rank one of the foremost, if not the foremost, feature at these great gatherings. The premiums enumerated by Mr. Clute may seem slightly extravagant, to persons who have never seen bees and honey figure to any considerable extent in agricultural and mechanical exhibitions and fairs, but to any reflecting individual, who takes into consideration the magnitude of the bee-keeping interest at the present time, and the illimitable millions of pounds of honey now "wasting its sweetness on the desert air," from want of the proper encouragement and development of the industry, the figures will seem modest indeed.

Sheep and Bee-Keeping.

An exchange gives the following reasons why bees cannot thrive on sheep pastures, and insists upon bee-keepers providing pasturage for bees:

It is easy to perceive why bees cannot thrive well on a sheep pasture. Sheep eat everything down very closely, and leave nothing in the shape of a flower upon which bees can subsist. There is no other reason for the popular belief that sheep and bees will not thrive together. The bees will not hurt the sheep in any way, but the sheep leave nothing for the bees to pasture in; that is the only difficulty, and where other feeding ground is provided for the bees than the sheep pasture, sheep and bees would thrive very well together.

Melilot clover and aromatic plants, such as mints and catnip, are the blossoms upon which bees seem to find the most continuous supply during the driest months. Bee-keepers should encourage the introduction of such plants, as they can grow harmlessly along hedges and fences. It may be thought that a few plants of each kind cannot benefit the bees to any extent. Certainly not. But a few plants here and there will produce seed, and finally make waste places become sources of the most delightful of sweets.

☞ Last Monday, "our pastor," the Rev. A. Goodfellow, came to our office for a "call," and with sparkling eyes, said: "Good morning, Bro. Newman; I'll give you a conundrum. Here is the latest; it is rather far-fetched, but good." We remarked that we were more of a *punster* than a diviner of "conundrums," but that we could enjoy "a good thing" at any time. "Well," he said, "why is a bee-hive like a diseased potato?" Of course we gave it up. He replied, "a bee-hive is a bee-holder, is it not?" We assented, but intimated that we could not see the *point*. He then added, "a beholder is a spectator." True, we replied. He continued, "and 'a specked tater' is one that is diseased, is it not?" We remarked that it was very far-fetched, indeed. He smiled, bowed himself out, and added, "put that in the BEE JOURNAL and here it is."

We have received a copy of Mr. G. M. Doolittle's Club List for 1884, and Circular of bees, queens, etc. It is a very handsome pamphlet, and is a credit to him as well as Mr. Root, the printer. His address is Borodino, N. Y. On page 5 we notice the following paragraph under the heading of "Remarks":

Newspapers are now an actual necessity, and the man who does not take at least one or more papers, is soon behind the times, and is also depriving himself of one of the greatest blessings of life. In no other calling in life is the knowledge gained from reading, of more benefit than it is to the bee-keeper. The bee-keeper who cannot afford to take a bee paper, is only penurious to his own injury, of many times its cost; therefore, I urge all into whose hands this circular may fall, to take at least one of the bee papers, that you may gain knowledge which will help you to work your bees to the greatest profit. The Weekly AMERICAN BEE JOURNAL is now an established fact, and is taken by nearly all practical bee-keepers. Its weekly visits are those which no bee-keeper can afford to dispense with, for the knowledge gained from *one* number is often worth many times its cost. The putting in practice of its teachings (and that of the other bee papers), is what helped me to secure \$1021.30 net profit from 60 colonies of bees during the past poor season, when basswood was the only tree or plant which yielded honey. The AMERICAN BEE JOURNAL is published in an attractive form, and it is hardly necessary for me to say that I consider it at the head of all the bee papers in the world.

Mr. D. has our thanks for so frankly giving his opinion of the practical value of the BEE JOURNAL.

☞ Mr. George Grimm, of Jefferson, Wis., has gone to Europe, and will be absent several months. He is the son of the world-renowned Adam Grimm, who was one of the pioneers of bee-keeping in America. He has our best wishes for a pleasant voyage and a safe return.

What and How.

ANSWERS BY

James Heddon, Dowagiac, Mich.

Cellar Wintering.

Will Mr. Heddon please answer the following:

1. Will a pipe 6x4 inches be large enough to ventilate a cellar containing 50 colonies?
2. Would the above pipe be sufficient unjoined to the stove-pipe, but 25 feet high?
3. Do bees always hum more or less when they are wintered in the cellar?

C. W. DAYTON.
 Bradford, Iowa, Nov. 28, 1883.

ANSWERS.—I have never been able to satisfactorily demonstrate that ventilation pipes in cellars and double houses did any good in wintering bees. Perhaps they do; though I have seen cellars full nearly all die with ventilation pipes attached, and all alive to a colony with no ventilation pipes, and every thing in wet, moldy condition.

1. 6x4 inches would be large enough for the interior of a pipe, either attached to a stove-pipe, or I should think if standing 25 feet high, though I have never tried that.

2. Answered above. I would let the bottom of the pipe extend down to within 6 inches of the bottom of the cellar.

3. I have known bees to winter well where a good deal of humming was kept up through their confinement. I have known bees to keep almost perfectly still during the same time, and they always winter well. I have found that changing the degree of temperature will change the tendency to roar or hum, but it will not prevent

or cure diarrhoea. Another thing. I found that in some winters 10° lower temperature kept the bees stiller than the still temperature of the preceding winter, when the number of colonies and hive ventilation was the same. This is one more of the unaccountables.

Frames Standing on the ends in Winter.

Will Mr. Heddon please answer the following question? Have you ever wintered bees on the Langstroth frame standing on the end in a case, packed with chaff? If so, what were the results?

J. G. NORTON.
 Macomb, Ill., Nov. 28, 1883.

ANSWER.—I have tipped Langstroth hives up at various angles, from a slight pitch to nearly standing on end, but I have never seen any better results by so doing. You need not be afraid of any derangement by changing the position of the combs. We used to winter box hives upside down with good results, and I have had the queen breed in a comb lying horizontal. If I considered it advantageous to make any change at all, my idea would be to give the hive a pitch a little more than 45 degrees, and do so just as soon as the surplus receptacles are removed in the fall. This will give the colony a chance to arrange their stores to their notion, according to the new position of the hive. In the *Kansas Bee-Keeper* for March 1883, I gave my ideas of wintering in shallow vs. tall hives.

✎ Much complaint was made last season of the delay in getting "supplies," which were ordered of the different "dealers" in the rush of the season. Now, to avoid a repetition, let all order early, and then if a delay does occur, it will not make as much difference to them as if the orders were sent in just as the goods were wanted for use.

✎ For \$2.75 we will supply the Weekly BEE JOURNAL one year, and Dzierzon's Rational Bee-Keeping, in paper covers; or in cloth for \$3.00. This is a rare chance to get the latest book of that celebrated German bee-master for a trifle. The price of the book alone is \$2.00.

✎ Owing to the death of our Secretary, Mr. T. Brookins, please announce in the BEE JOURNAL that the annual meeting of the Champlain Valley Bee-Keepers' Association, will meet in the parlors of the Addison House, Middleburg, Vt., the second Thursday in January, 1884.

J. E. CRANE, Pres.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL.
 Monday, 10 a. m., Dec. 10, 1883.

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

HONEY.—The market is slow; arrivals exceed the demand which, however, has improved some. There is a better demand for comb honey, and supplies are short, which, no doubt, is temporary, as usual. Last year at about this time, comb honey was at its highest, when our sanguine friends very naturally held on, expecting more. However, large supplies commenced to arrive, and prices kept going down steadily. Bee-keepers in general bent their energies on the production of extracted honey last season, more than ever before. We had a large crop, and extracted has been dull so far, not only because of the large supply, but because manufacturers complain of dullness in their business. Consequently, we have reason to believe that the present slow market is temporary.

The present state of the honey market gives our bee-keeping friends another chance for a disappointment, to wit: That of over-production of comb honey another season. This is merely an idea of my own, and our friends may take it for what it is worth.

Extracted honey brings 7@9c. on arrival. Best comb honey, 16@17c. in small sections.

BEE-SWAX.—Is of ready sale at 26@30 on arrival.
 CHAS. F. MUTH.

NEW YORK.

HONEY.—White clover and basswood in 1 and 2 lb. sections, 17@21c. Dark and second quality, 14@15c.; extracted white clover in kegs and barrels, 9@10c.; dark, 8c.

BEE-SWAX.—Prime yellow, 27@29c.
 H. K. & F. B. THURBER & CO.

CHICAGO.

HONEY.—The market remains without change from that of last week. Dealers and retailers buy only enough to supply the demand for present use. It is impossible to place lots, or entire shipments, owing to the reluctance of dealers to buy in advance of immediate wants. Prices obtained for white comb in 1 lb. sections, 18@20c.; 1½ and 2 lb., 15@18c., according to beauty of same. Extracted honey, 8@10c. per lb., according to color, body and flavor.

BEE-SWAX.—Yellow, 33c.; medium, 28@30c.
 R. A. BURNETT, 161 South Water St.

KANSAS CITY, MO.

HONEY.—Receipts of comb honey on Eastern account still keeps everything that is of fair quality well cleaned up. Choice 1 and 2 lb. sections are taken on arrival at 18c.; larger sections and dark honey 16@17c. Sales of extracted for the past week, about 4,000 lbs., mostly at 8 cts. The feeling for extracted is a little better, and I look for a firmer market.

JEROME TWICHELL, 535 Delaware Street.

SAN FRANCISCO.

HONEY.—There has been some attempts at negotiation in comb honey on Eastern account this week. The market for extracted is dull, and it is doubtful if more than 7½c. could be realized for choice water white in a wholesale way. White to extra white comb, 16@18c.; dark to good, 12@14c.; extracted, choice to extra white, 7½@8c.; dark and candle, 6½@7c.

BEE-SWAX.—Wholesale, 27½@30c.
 STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY.—Choice comb in light supply, fair demand and firm at 15@17c. per lb.; dark, broken and poorly handled, dull at less. Strained and extracted steady at 6½@7½c.; choice in fancy pkgs. more.

BEE-SWAX.—Salable at 28c. for prime.

W. T. ANDERSON & Co., 104 N. 3d Street.

CLEVELAND.

HONEY.—Honey continues in excellent demand, as reported last; every lot of choice white comb is taken up as fast as it comes at 18c. in quantity for 1 lb. sections, and an occasional sale at 19; in a very few instances only, 20c. has been reached. Broken lots and second quality is very slow sale. For extracted there is no demand.

BEE-SWAX.—Is eagerly inquired for at 28@30c., but none to supply the demand.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY.—Our market is very quiet on honey. We quote 16@18c. for best 2 lb. sections—18@20c. for best white 1 lb., and 10c. for extracted.

BEE-SWAX.—We have none to quote.

BLAKE & RIPLEY, 57 Chatham Street.

✎ Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra

CORRESPONDENCE

For the American Bee Journal.

Readily Movable Hives.

JAMES HEDDON.

Much of value has been said about movable combs, and while nearly all know of their worth, few give due importance to readily movable hives.

First let me tell you something about how my hive is made, and then you can better form an idea of what I mean by "readily movable hive." The inside measure is 10 inches deep by $11\frac{1}{2}$ wide by $18\frac{1}{8}$ long, and takes 8 standard Langstroth frames. The depth, 10 inches, we always make $10\frac{1}{8}$ to allow for shrinkage, which will take place in after years, even if we use the most thoroughly seasoned lumber. The sides of the hive are $\frac{3}{4}$, the ends $\frac{7}{8}$, the bottom $\frac{5}{8}$, the cover $\frac{5}{8}$. From these dimensions we do not vary, and any hive that does vary from them, I believe to be just that much "off."

I fancy I have more good reasons than I care to take space here to enumerate for using these thicknesses of lumber. Our bottom boards are nailed permanently to the hive, and this fact, and the thicknesses of the lumber thus given, makes our hive easily movable.

The foregoing describes the brood-chamber, and the surplus department consists of two to four cases, the sides of which being $\frac{3}{8}$ of an inch thick, the partitions $\frac{1}{2}$ inch, and each case weighs only about 4 lbs. These and the honey-board make the hive complete. The cases, when on, being covered by the brood-chamber cover, and each having a capacity for about 25 pounds of honey, they are used upon the tiering-up plan, and not more than three are usually used on a hive at one time. We use no outer case, because none is needed, and in three or four ways such a covering is much worse than useless. The reader will observe that my hive, whether with or without the surplus department, is very light, and easily handled compared with others.

Now, when one comes to manage large apiaries, pushing business upon that scale which necessitates dispatch, he will find a hive possessing this easily movable principle of more value than one possessing all the advantages derived from cumbersome hives. Our methods of securing increase, depositing laying workers, preventing increase or after swarms, and many other manipulations which we find we can accomplish much quicker and better with our peculiar methods than by any other we know of, demand the use of a light, easily movable hive. Such are not only almost a necessity with the less muscular, but very pleasing to all who carry on business in a practical and profitable manner.

It is my opinion that this problem of wintering, or cause of dysentery, is

soon to be understood, and it is further my belief that when it is, the next important question will be, "now that I know how to winter my bees with certainty, how can I do this the cheapest," and this will lead to cellar wintering; and here, again, comes in the advantage of the "readily movable hive." About one-third of the time I have spent speculating and experimenting in the line of apiculture, has been spent in hives and fixtures pertaining to them, once supposing that, hidden in mysterious depths, was an almost automatic hive. I long since found out how mistaken was that supposition, yet the thoughts and experiments were not in vain, for I now enjoy a hive much nearer to it than the one used in the past time referred to.

I am aware that no one hive embraces, or can embrace all, or nearly all, the valuable features pertaining to hives that oftentimes combine one such feature. Such combination positively necessitates the omission of two or three others equally valuable, forcing us to make that more difficult selection of the hive combining most worth, in principles, all things considered. Before closing, I wish to state what I believe to be leading principles, which I have faith that the future wisdom and practice of beekeepers yet to be, will bear me out in.

1. All hives should be easily and readily movable.
2. The stories should move off and on to each other without the necessity of the least upward or downward motion; that is, no telescoping principle.
3. There should be no dead air space or double covering over the surplus room.
4. The sections should never rest on each other or the brood frames.

With your permission, I will quote from that portion of the specifications of the Langstroth patent, relative to the shallow chamber, or air space above the frames or bars.

"The apertures or bee passages in the honey board may be made without being liable to be closed by the bees, as they so frequently are in hives which have not this shallow air space. It will be seen that the bees can pass into this shallow chamber from between all the ranges of comb, and from the front and rear walls, *d*, of the hive, and the sides (*c*, *e*, *f*, *g*, *h*, *i*, *j*, *k*, *l*, *m*, *n*, *o*, *p*, *q*, *r*, *s*, *t*, *u*, *v*, *w*, *x*, *y*, *z*, *aa*, *bb*, *cc*, *dd*, *ee*, *ff*, *gg*, *hh*, *ii*, *jj*, *kk*, *ll*, *mm*, *nn*, *oo*, *pp*, *qq*, *rr*, *ss*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*, *fff*, *ggg*, *hhh*, *iii*, *jjj*, *kkk*, *lll*, *mmm*, *nnn*, *ooo*, *ppp*, *qqq*, *rrr*, *sss*, *ttt*, *uuu*, *vvv*, *www*, *xxx*, *yyy*, *zzz*, *aaa*, *bbb*, *ccc*, *ddd*, *eee*

For the American Bee Journal.

Prevention of Swarming.

L. L. LANGSTROTH.

Believing that it is right to hive swarms which cannot be kept from issuing on Sunday, let me make some suggestions to those who, like myself, wish on this day to have as little as possible to do with bees.

1. By giving the material for starting queen-cells on Saturday, there will be no occasion to care for them on Sunday.

2. Use some proper device for confining the queens on Sunday, or any other day when you do not wish them to lead out swarms. This is a point to which I have given much attention. On page 174 of the third edition (1859) of my work, I say,—

"As the queen cannot get through an opening 5-32 of an inch high, which will just pass a loaded worker, *if the entrance to the hive be contracted to this dimension, she will not be able to leave with a swarm. This method of preventing swarming requires great accuracy of measurement, for a very trifling deviation from the dimensions given will either shut out the loaded worker, or let out the queen. These (adjusted) blocks, if firmly fastened, will exclude mice from the hive in winter. When used to prevent all swarming, it will be necessary to adjust them a little after sunrise and before sunset, to allow the bees to carry out any drones that have died."

In my second edition (1858), page 202, referring to this device, I say:

"By this arrangement, all swarming on Sunday, or any other day when the apiarian does not desire it, may be prevented."

Also, page 203,—

"It also may be found, on further experiment, that the entrances to all the spare honey-receptacles may be so adjusted that the queens will never be able to enter them for the purpose of depositing eggs."

Also, page 202,—

"A very important use may be made of blocks thus arranged, to get rid of the drones. In that part of the day when they are in full flight, adjust the blocks so that they cannot enter. Toward dark, or early next morning, they will be found sprawled out upon the alighting-board, or hanging in clusters under the portico, and may be given to chickens, which can easily be taught to devour them. In a few days nearly all the drones in the apiary may be thus destroyed."

*Huber does not give the size necessary for confining a queen, but he spoke of a GLASS TUBE adjusted so as to pass out a worker, and not a queen. The smallest queen I ever saw could not get through my blocks. Although the workers are at first slightly annoyed by them, they soon become accustomed to them, as they do not confuse them by presenting the entrance in a new place. The ventilation not depending on this contracted entrance, abundance of air can be given to the bees when the blocks are adjusted so as to confine the queen. All health for the last two summers has prevented me from giving this method of preventing swarming such a full trial that I can endorse it, except for temporary purposes.

A THEORY which may seem so plausible as almost to amount to positive demonstration, may be encountered by some unforeseen difficulty, which speedily convinces even the most sanguine that it has no practical value.

Further experience showing that it was often quite difficult to maintain the 5-32 of an inch by depressions cut in the entrance-regulating blocks, I fastened a few 5-32 strips with clinching nails between two pieces, each $1\frac{1}{2}$ inch long (the length of the usual entrance), the lower strip having two bevels to facilitate the exit and entrance of the bees. A central hole, governed by a cork, allowed dead drones to be easily dragged out, or a young queen to fly for mating. Still the bees would worry from having to crawl too far under such narrow dimensions. At last the 5-32 was cut in a thin metal strip, and such a device enabled me both to prevent my costly imported queens from eloping, or running the risk of being destroyed by stray queens.

On a recent visit to the large apiaries of my friend, Mr. D. A. Jones, of Beeton, Ontario, I saw all the points, on which I had labored so long, carried out in a much more satisfactory manner by means of his perforated zinc plates. His *bee-guards*, made of these plates, allow the workers to pass in the freest possible manner, while the ventilation of the hive is not in the least interfered with. The only improvement in them which I can suggest would be to punch out a central hole, governed as in my device, by a small cork. These can be adjusted in a few moments, and Sunday swarming, or swarming on any day not convenient, be prevented without at all worrying the bees. By them, all bad or superfluous drones may be quietly destroyed, by shaking off the bees from their combs, in front of their hive, the queen, of course, being properly rescued. Some may find this the easiest way, more especially with black bees, for finding a queen, or of making it absolutely sure that there is none in a colony to which we wish to introduce a valuable queen. Mr. Jones uses sheets of this perforated zinc to confine the queen to the lower story of the hive, or to any desired part of the brood-chamber, so that she cannot enter the surplus honey receptacles. These sheets also prevent the bees from building small combs between the upper and lower sets of frames—a thing which has often caused so much trouble in hives where more than one story is used.

I see no reason why sections for comb honey may not be set to the best advantage directly on these sheets. Before giving up my apiary, I found that small boxes were much more readily filled by Italian bees, when put directly on top of the frames; and that, however admirably the shallow chamber answered for black bees, the Italians plainly wanted nothing to do with it. How much time and money have been spent in trying to control the mating of our queens! As far as practical results are concerned, have we advanced at all beyond the Kohle process, given so many years ago in the AMERICAN BEE JOURNAL, by which young queens and drones from a selected colony were made to fly later in the day than the other drones? May we not, by Mr. Jones' bee-guards, make a still closer approximation to

the mating of our queens with our best drones? If we are not liable to be troubled by drones outside of our own apiaries, how easily we can shut in those that we do not desire to breed from! or, if troubled by drones from bees in the woods, or from colonies too near us, we can confine our young queens, and the drones of selected colonies, until it is so late in the afternoon that other drones have ceased to fly; then by pouring a little thin sugar syrup into the proper colonies, we can quickly tempt both queens and drones to take wing with the excited workers. As the power to control the mating of our queens is fully as important as the control of the same point in our domestic animals, I shall never cease to believe that, sooner or later, we shall obtain the desired result.

The care with which queens and drones can be confined by the Jones bee-guards, without at all lessening the ventilation of the hive, and with the minimum of interference with any of the labors of the colony, promises to open a wide field for many important processes. It may now be possible, in the hands of careful breeders, not only to keep different races of bees pure in the same apiary, but to build up permanently any desired cross between the different races.

Few bee-keepers, who keep up with the modern improvements, are ignorant of the great services of Mr. Jones, in searching the world, at great expense, to procure the best bees. By his great enterprise he has done more than any one living, to make American bee-keeping known in the Old World. We have been much slower, however, to recognize how much he has done for practical apiculture by his many ingenious devices, and, most of all, by the costly experiments and machinery by which he secured for us his perforated metal sheets.

Oxford, O., Nov., 1883.

☞ The Ohio bee-keepers will hold their annual convention in Columbus, O., Jan. 14, 15 and 16, 1884. All interested in bee-culture are invited. The following subjects will be discussed: "How to winter bees successfully." "Are the new races of bees a success?" "What can we do to prevent adulteration of honey?" "How to create a home market for honey." "How many colonies can be kept in one locality?" "Can we do without separators?" "Which are best, deep or shallow frames?" "What shall we do with second swarms?" "How many brood frames are necessary in a hive?" "Which is the most salable section, one-half, one or two pounds?" "Is it advisable for all bee-keepers to adopt a standard size of frame?" "What is the most desirable width of sections?"

The above questions will be discussed by eminent men, such as Rev. L. L. Langstroth, Dr. Besse, S. D. Riegel and others, and in addition to the above, Prof. Lizenby, of the Ohio University, will deliver a lecture on "Honey-producing plants," also Mrs. Jennie Culp will read an essay.

C. M. KINGSBURY, Sec.

For the American Bee Journal.

"The Pollen Theory"—Facts.

A. R. KOHNKE.

Exactly what we want. Fact No. 1. Colonies affected with the bee diarrhoea have always pollen in their hives; fact No. 2. colonies wintered largely or exclusively on sugar syrup escape the disease; fact No. 3. voidings of the bees affected with the disease have the same color as pollen, there being no other substance in the hive having the same effect to color.

Now, for Mr. Doolittle's experiments, as stated in No. 48, page 606. Mr. D. has tried to force bees by starvation to eat pollen, in which he failed. This proves nothing but his failure; it does not prove that the bees do not eat pollen, for we know they do. Pollen is not, and cannot be the primary cause; certainly not. Primary causes are those which compel the bees to eat the pollen when they ought not to; viz.: out of season. If Mr. D. had furnished besides pollen and little or no honey, those other conditions necessary to produce the disease, I dare say he would have succeeded.

Now, I wish Mr. D. and such other bee-keepers as are interested in it, would experiment as to how to produce the disease, at will, whenever they wish; than we would arrive at facts and try to avoid such conditions.

Like Mr. D., I have also tried to force bees to eat pollen, just one week later than Mr. D.; viz.: Oct. 19, this fall. I had some very old combs, full of honey, which I did not want to use next spring. I extracted the honey, and found two-thirds of the frames filled with pollen and covered with honey. Quite a quantity of the pollen being soaked through with honey, was thrown out. Having some colonies which are rather scant in stores, I fed five of them of this honey, on the above date, which I chose, to avoid robbing, as it was too cold for the bees to fly, as also the 20th and 21st. On the 22d the bees had a chance to fly, and every colony thus fed showed signs of bee diarrhoea. At the same time other colonies, part of which were fed with sugar syrup and part with powdered sugar, made into a dough with clover honey, were not affected.

By all means let us have facts. I have drawn conclusions from such as have come under my observations. Of course, I am liable to err; but, as long as my conclusions are not proven to be erroneous, I think I am justified to consider them correct.

To conclude, I will add, that I lost 2 colonies, last winter, by this disease (?) which had not a particle of brood, but the honey was gone clean, and part of the pollen eaten.

Youngstown, O., Nov. 31, 1883.

The annual meeting of the Lorain County Bee-Keepers' Association will be held in the Court House at Elyria, Dec. 19, 1883.

My Experience with Syrian Bees.

L. A. LOWMASTER.

I will give my experience with Syrian bees, and as I do not rear queens to sell, I have "no axe to grind." When I first heard of the Syrian bees, I was anxious to try them, so I sent to Mr. Jones for two queens, which I received in July, 1881, and as it was too late in the season to test them thoroughly, I concluded to keep them until I was satisfied whether they were inferior or superior to other races of bees.

In the fall of 1881, when I prepared them for winter, they were stronger in numbers than the rest of my bees. They stood the winter well, and in the spring of 1882, they were more populous than the Italians and Albinos; so I thought that I would rear a few queens for my own use, and I succeeded in rearing some very fine queens, and as I did not put on any boxes in 1882, I did not get any surplus honey; but when I prepared them for winter in the fall of 1882, I found nearly every colony had twice as much honey as they needed to winter on, having the brood-chamber full, with the exception of two or three combs, which was about half-full of brood.

The winter of 1882-83 was hard on bees in this part of the country, but my Syrians came through in good condition; they wintered better than the rest of my bees, excepting the Cyprians, which I had 14 miles from my home apiary.

Nearly all of the rest of my bees (Italians, Albinos and hybrids) were weak, and in a deplorable condition, so I had to take frames of hatching brood from the Syrians to build up weak colonies, and when the combs were full of brood, and the young bees commenced to gnaw through, I took them out and exchanged them with the weak colonies the second time.

After taking all the brood out twice, it did not seem to affect them at all; and by the time white clover was in bloom, they were stronger than the Italians and Albinos, and they commenced to work in the sections two weeks before the Italians (I did not take any brood from the Italians). The Syrians cast larger swarms, besides gathering more surplus honey than the Italians ever did for me.

The young colonies filled 8-frame Langstroth hives, and stored more honey in the sections than did the old colonies of Italians and hybrids, while the Albinos and hybrids only filled the brood-chamber, and only gathered enough honey to winter on this fall. When I prepared them for winter they all had plenty of honey to carry them through safely, and more.

I find the Syrians splendid honey-gatherers; they work early and late; they carry heavy loads of honey, and there are lots of them. And yet, some say they are no good.

The Albino bees are not as good as the Italians. I have had them on trial for three or four years, and I

know whereof I speak. I never got as much honey from them during all this time as I did this year from one colony of Syrians. I have "weighed them in the balance" and "they are found wanting." They had their day, and must step down and out. I will keep one or two colonies of them just to look at.

One writer says that he would like to see the man "that can tell the difference between the Italians, Syrians and Cyprians." Now, if there is no difference, why is he afraid to try them, before he says they are not as good as his strain of bees? If he will come here, I will show him the difference between the Syrians, Italians and Cyprians.

I find no difficulty in telling one from the other, and even queens fertilized by Cyprian drones, produce bees which are readily known from pure Syrians. The general color, markings and movement of these bees, say nothing of their working qualities, are sufficient to enable one to distinguish the races readily, but there are also other points in which they differ. Upon opening a hive of Syrian bees, and using smoke, the workers crawl about in a manner somewhat like black bees, but soon become quiet, if carefully handled. The workers fly in a darting manner, and alight quickly when near the desired spot, or, perhaps, it cannot be better expressed than to simply say they flit from point to point, while the Cyprians and Italians exhibit a more moderate motion.

The Syrian bees present a decidedly gray color, though the abdomen has a ringed appearance. The ground color is a grayish-black; the body, before the fuzz is worn off, being very light; the gray-colored fuzz is very thick on the thorax, and the latter half on each segment of the abdomen, especially those after the yellow bands, are thickly set with light-colored fuzz, giving them a striking appearance. The three yellow bands are very prominent and yellow.

The shield between the wings is not as prominent as with the Cyprians, though still visible. The Syrian drones are very fine, large and vigorous, and have an exceedingly thick coat of whitish and blue-tinged "fuzz" over the greater part of the thorax, especially on the sides, and a very noticeable amount on the abdomen. In proportion to their bodies, I think their wings are somewhat larger than those of the Italians or Cyprians.

The Syrian queens are wonderfully prolific, laying an incredible number of eggs in a season; in fact, I would not be surprised if a Syrian queen would lay as many eggs in one season as blacks or Italians do in a life time. The Syrian queens are very small when not laying, and some persons think them ordinary looking; but give them plenty of bees and room, and they get very large, and fill a frame of comb with eggs so rapidly that you would imagine it impossible for one queen to deposit them so fast. One Syrian queen can lay eggs enough in 21 days to make from 4 to 6 colonies of bees, if they were all cared for and

hatched. This may seem surprising, but try it and be convinced.

The Syrian bees build less drone comb than the blacks or Italians; they protect their stores against robbers with such determination that they often catch the robber on the wing, around the hive, and punish them before they even get time to alight; in fact, they are robber proof.

Their bodies are more telescopic, which enables them to carry larger loads of honey, and to contract their bodies at other times to quite small proportions.

They are swift on the wing, flying so rapidly that only those heavily laden with honey can be secured on the bloom. No race of bees will fly more rapidly, or further (when necessary) in search of honey than will the Syrians. They have been known to fly 6½ miles to obtain pasturage. I have seen my Syrians 2½ miles from my apiary; how much further they went I am unable to say.

As honey gatherers, they are not excelled, and both the Cyprians and Syrians will make a greater effort to obtain honey when there is a scarcity than the other races, and are valuable for comb honey. My Syrians work on the first crop of red clover (large heads) there was a plentiful flow of white clover honey; and I never saw bees thicker on buckwheat than I saw the Syrians on the red clover this season.

Mr. Morris, who lives 1½ miles from my apiary, one day last summer came to see my bees, and he told me when he was cutting his red clover for hay, his son remarked: "Father, look at the bees working on the red clover." Mr. Morris said he got off the machine to see if they were his bees, but they were not; they were a different race—his are black bees—when I showed him my Syrians, he said they were the bees that he saw working on his field of red clover, and he said that was the first time he ever saw bees working on red clover. He is a man that can be relied on.

The Syrians winter better than the Italians, come out better in the spring, and do not dwindle so badly. Everything considered, I regard the Syrian bees as the most superior race ever imported into this country, and that, when they have been subjected to the same careful selection and breeding as have the Italians, they will command more prominence than have the Italians. I would most emphatically affirm that the Syrians have a larger number of the necessary qualities than any other race or strain of bees. I will admit that I am using strong language, but my experience with this race, regarding queen-breeding, honey-gathering and wintering, fully warrant me in making the statement. These, with many other experiences and facts connected with the Syrians, fully support me in stating that in them we have the foundation on which to build the *Apis-Americana*. I am not prejudiced against any race of bees, and the above is an honest description of the Syrians as I see them.

Belle Vernon, O., Nov. 22, 1883.

For the American Bee Journal.

Shall we use Old Combs?

C. H. DIBBERN.

It has been claimed from time immemorial that pieces of combs are invaluable to the bee-keeper. I have worked on this line myself for years, but have come to the conclusion that it is valuable only for the wax it contains to be made into foundation. I usually extract all partly-filled combs in the fall, and save them carefully to be used again the following spring. After practicing this for years, I am satisfied it is poor policy. However it may have been, before the advent of foundation, I am satisfied that, like Mr. Heddon's plan of transferring, it is all changed now.

During the past summer I used a good many nice white combs in two-pound sections, that had been built the year before, and as the sections were nice and new, thought I had a bonanza in getting these filled and capped early. Now, what was the result? The bees entered the sections eagerly, and in less than two weeks a good part were capped. By this time I was out of empty combs, and was putting on sections filled with foundation. Now, I was beginning to think of taking off some of the sections that had been filled with empty combs, and what was my disgust and disappointment in finding the bees uncapping it again, and a good deal of it with the caps all burst off. Well, I could only leave it, and soon commenced to take off the sections that had been filled with foundation, that were as fine as I ever saw. I kept taking off some of the sections that were full of empty combs about all summer, and most of it went into No. 2 honey, while that built on foundation, made at the same time, was extra nice.

The explanation is very simple. When honey is coming in liberally, the bees will fill comb that is already built too fast, and cap it over before it is ripe and souring ensues. If the bees are compelled to build the comb, or draw out foundation, the cells are filled so gradually that the honey will keep by the time the cells are built out. Every particle of comb should be saved, and carefully melted up and made into foundation. It may look like sacrilege to melt up nice white comb, but it will pay.

Milan, Ill., Nov. 27, 1883.

Trenton, Ontario, Convention.

A meeting of bee-keepers in the vicinity of Trenton, Ont., was held at Trenton on Oct. 16, 1883. P. C. Dempsey was elected Chairman, and J. H. Peck Secretary. Constitution and by-laws were adopted, and the following were elected officers for the ensuing year:

President, P. C. Dempsey; Vice-Presidents, W. C. Wells, C. W. Post, S. Powell, J. G. A. Wallace, H. G. Stafford, Edward Caverly, Allen Pringle, John Mitchell, R. A. Brook, A. D. Allen, D. J. Hawley; James H.

Peck, Secretary-Treasurer; H. F. Whittier, Janitor.

THE BEST METHOD OF WINTERING BEES.

W. C. Wells winters his bees in a cellar under his shop—has a sub-earth ventilation by means of 4-inch tile pipe—prefers 6-inch tile. When he prepares his hive for winter, takes empty combs out of the hive and crowds the remaining sections up close, by means of division-boards. Makes a frame the size of the top of the hive, and about 2 inches deep, tacks on cotton cloth, and fills with sawdust, which allows the dampness to pass off, while it retains the animal heat in the hive. Packs his colonies about the middle of October, and puts them into the cellar about the middle of November. Keeps the temperature as near 45° Fahr., as possible.

W. C. Post winters his bees similarly to the plan of Mr. Wells, but ventilates by means of the cellar windows.

S. Powell winters his bees in a cellar with caps removed, and nothing but a coarse piece of bagging placed over the top of the hive—ventilates his hives by means of a hole in the back part of the hive, covered by fine wire cloth.

H. G. Stafford winters his bees similarly to Mr. Wells—has sub-earth ventilation for his cellar, in which he winters his bees.

J. G. A. Wallace wintered his bees, last winter, in the stone basement of a barn, and lost 58 out of 66 colonies; attributes his loss entirely to sour honey.

P. C. Dempsey winters his bees in bee cellars, specially built and ventilated for that purpose. His experience covers a period of thirty years. Thinks the principal cause of failure is by not putting bees into good winter quarters before hard freezing weather.

D. J. Hawley winters bees in a good cellar, without any special ventilation except from the bottom of the hive. Does not think ventilation from the top of the hive advisable, as it is essential to keep up the animal heat in the hive. Rarefied air caused by animal heat will ascend to the top of the hive, while all the foul gases will descend to the bottom of the hive. Hence, the necessity of bottom ventilation. Where a very large number of colonies are kept in the same cellar, general ventilation is necessary in addition to hive ventilation.

J. H. Peck wintered his bees successfully from the instructions he received from the Hon. Lewis Wallbridge (now Chief Justice of Manitoba), from whom he obtained his bees. Had no ventilation, except from the bottom of the hive. Thinks if bees are put into an ordinary cellar, with at least 30 pounds of honey to each hive, and caps removed, and cushions of sawdust or cotton batting placed on top of the hives, and that where not more than 10 or 12 colonies are placed in the same cellar, that cellar ventilation is not absolutely necessary, but perhaps advisable. His bees were housed, last year, 150 days,

or 5 months and 9 days. This is a very long period to feed bees, but if the temperature can be kept up and bees have a good supply of pure honey, the loss by this method of wintering bees will be comparatively small.

SUN AND SHADE FOR BEES.

W. C. Wells prefers apple trees as shade for his bee hives in very hot weather.

C. W. Post prefers fruit trees and grape vines for bee shade.

J. G. A. Wallace preferred large Missouri currant bushes as bee shade. He had been very successful in that way.

S. Powell preferred large board caps placed on the top of the hive 6 or 8 in. larger each way, than the top of the hive. This afforded ample protection against the rays of the sun, and prevented the melting of honey in the sections.

INCREASE OF BEES IN THE SPRING.

W. C. Wells and C. W. Post agreed that the best plan to get a large increase of bees, was to spread the brood frames by removing the division boards and inserting empty cards of combs as fast as the bees are able to cover them. Care should be taken not to spread the brood too fast, as a cold night might chill the brood and produce foul brood.

THE BEST TIME TO TRANSFER BEES.

J. G. A. Wallace prefers the spring when apple trees are in blossom. Messrs. Dempsey, Wells, Post, Hawley and Powell all concurred in the view.

Question by Mr. J. H. Peck.—“Which is the best hive for all purposes, a one or two-story hive?” All agreed that a two-story hive was best for all purposes, for the following reasons:

1. All surplus honey, as a rule, was stored in the upper story and the brood-chamber below.

2. The honey above is clearer and free from brood, and can be extracted without injury to the brood, and is more accessible, the lower chamber being left almost entirely for brood, and comb honey is cleaner, as the bees do not travel over it in passing out of the hive.

COMB HONEY, WITH OR WITHOUT SEPARATORS.

Mr. Wallace was of the opinion that he could get more honey without separators.

Mr. Hawley had tried both plans during the past season, and obtained as much comb honey with separators as without. By the use of the separators his comb honey was in much better condition for shipping in the usual size crates than without separators; about one-eighth of the comb boxes were bulged out with honey, and could not be sent out in the usual sized shipping crates.

THE BEST RACE OF BEES.

Mr. Post thought the Italians were the best kind of bees, had destroyed

his Cyprian and Syrian queens in consequence of their stinging propensities, and kept none but Italians.

Mr. Dempsey did not like Syrian bees, they were such ferocious stingers. Was better pleased with Italians and Cyprians.

Mr. Hawley preferred a cross between the Cyprians and the Italians. By this means the excellent working qualities of both races were obtained coupled with the prolificness of the Cyprians.

Mr. Stafford preferred the Italians as a class of bees.

Mr. Peck got his bees as pure Cyprians, but had been informed that they were Italians. They were prolific, and good workers, fighting propensities pointed, but by the aid of a “smoker” had no trouble to manage them.

INTRODUCING QUEENS.

Mr. Post makes a cage out of wire netting, an inch and a half wide, 4 inches long, and $\frac{3}{4}$ of an inch thick, in which he placed a queen and about one dozen working bees, and inserted in the hive between two cards of honey and leave them there for about 48 hours. If the bees are quiet, liberate the queen, and if not quiet in the hive, leave them for 24 hours longer before letting into the hive.

Messrs. Wells and Wallace adopted the same plan.

THE BEST HONEY PLANT.

All agreed that basswood is the best honey plant.

ARE BEES BENEFICIAL TO FLOWERS?

Mr. Stafford stated that his orchard near his bees bore far more fruit than any of his neighbors, the past season.

Mr. Dempsey said that portion of his orchard near his bees produced a fair crop, while the more remote portions bore no fruit worth speaking of. All said that bees were beneficial to flowers.

THE BEST PLACE FOR MARKETING HONEY.

It was agreed that Toronto and Western Ontario afforded the best market for honey, as the people of the Province of Quebec did not consume as much honey in proportion to the population as the people of Ontario.

H. G. Stafford had an average of 190 pounds of extracted honey from each old colony, and an increase of 3 swarms from each old colony, this being the largest yield reported.

The number of colonies represented at the meeting was 1,003. The total number of pounds was 54,000, being a fraction less than 55 pounds per colony. It must be borne in mind that average is based upon the count at the close of the season, and most of our bee-keepers are working to increase their colonies of bees instead of for surplus honey.

W. C. Wells, seconded by H. G. Stafford, moved that the next regular meeting be held in the city of Belleville during the month of February next. Carried.

For the American Bee Journal.

Pollen and Dysentery.

W. Z. HUTCHINSON.

Away back in Vol. I. of the AMERICAN BEE JOURNAL, on page 233, I find the following “Analysis of the Excreta of Bees,” by Donhoff.

1. “*Remains of Pollen.*” I boiled the excrement in caustic potash lye slightly diluted. After filtering, I washed the residuum in hot dilute muriatic acid. What was left after again filtering, could from its insolubility, be only the remains of pollen. It appeared, under the microscope, like an indistinct granular mass.

2. “*Uric Acid.*” I immersed the excrement in concentrated sulphuric acid, in which uric acid remains undecomposed. After carefully decanting the liquid from the resulting carbonaceous mass, I added water; and then washed the precipitated matter in water. I now added one drop of liquor ammoniaci, and one drop of muriatic acid. On heating, the mass assumed a purplish hue—the characteristic reaction of uric acid.

3. “*Hippuric Acid.*” I boiled some excrement in caustic potash lye. After filtering, I added dilute muriatic acid; and obtained a precipitate which proved to be composed of uric and hippuric acid.

“According to an approximative estimate, the excreta of bees consists of about one-third uric and hippuric acid, and the residue of indigestible portions of pollen.”

Now, dysentery or bee-cholera is simply an overloaded condition of the intestinal canal, with no opportunity of flying in the open air to discharge feces; and if this fecal matter is two-thirds pollen, is it not a logical conclusion that the more pollen there is consumed, the sooner will the intestines become overloaded?

Last winter I had colonies die with dysentery, in its worst form, early in January, before a particle of brood had been reared; hence, it certainly was not brood rearing that caused it; and if the fecal matter discharged by the bees is two-thirds pollen, those colonies certainly consumed large quantities of pollen at a time when no brood was being reared. I also had some colonies the same season that were given empty combs in the fall containing no pollen, and were then fed a syrup made from pure cane sugar, and when the bees from these colonies flew, they discharged so little fecal matter that it was scarcely noticeable, and some of them were kept in the cellar, without a flight, all winter. Thirty-two colonies were buried in a clump, the same season, and all, except those having sugar stores, suffered, and some died from dysentery. When taken out in April, no brood had yet been reared, but a few colonies had fresh laid eggs.

Rogersville, Mich., Dec. 3, 1883.

Sending Queens by Mail.

FRANK BENTON.

The communication on the above subject, on page 511 of the *AMERICAN BEE JOURNAL* for Oct. 17, conveys the idea that "the first live queen that ever crossed the Atlantic" by mail, was the one sent Aug. 2, by Mr. G. M. Doolittle. The following is verbatim from a letter in my possession. Notice the date.

"BEETON, July 6, 1883.—MR. FRANK BENTON, Munich, Germany.—*Dear Sir:* We received a queen from you in a mailing-cage. Most of the bees were dead. I think there must have been at least double as many bees as could get food and water. The live ones were in fine condition... Too many bees are worse than not having enough. I have instructed the boys to send you a cage of bees, and you can report....

With kind regards to Mrs. Benton and yourself. Yours very truly,

D. A. JONES.

The queen above referred to was an imported Syrian, mailed here during the month of June. She had previously stood a long journey by mail, having been prepared according to my instructions in Beyrout, Syria, and had come via Alexandria and Trieste to Munich, a distance of about 2,500 miles, part of which is in a sub-tropical climate, very trying to bees in confinement. About 30 workers were sent with the queen; an experience of several years in sending queens by mail on sea-voyages of 2,000 to 3,000 miles having convinced me that more than 20 workers give better results than a smaller number.

The food was pure sugar candy. The water was in a tin bottle, having a pin-hole, the latter made in the middle of solder to prevent its closing with rust. The cage itself was a strip of pine 5½ inches long, 1½ wide, and 1½ thick, containing three auger holes 1¼ inches each in diameter, the bottom of each being left about ¼ of an inch thick. The middle hole, which contained the bees, had several small air holes on each side. The candy was in one end, and the water bottle in the other. A wire-cloth and a card covered the open side.

This cage was illustrated in the *British Bee Journal* for July 1880, and a comparison shows that Mr. Doolittle's cage does not differ in any essential point, though he did not choose to supply water, and used a different kind of food.

The queen I sent went from Bavaria (after the long journey from the East) to the western part of Canada, and could not have been less than 16 or 17 days on the way. I had previously sent queens by mail from Cyprus and Syria to various parts of Europe, some of which were even 14 days—the time Mr. Doolittle's was on the way to Scotland—and since then I have a good many letters from parties in the United States, telling me of the safe arrival of queens that had been 18, and

and others 19 days on the way by mail; one even that states a queen which was 21 days on the way, "arrived in fine condition, but two of the workers dead."

Thus it is seen that, so far as is now known, the first queen that ever crossed the Atlantic by mail alive did not come from America to the Old World, but went from this side of the water, westward. I have spent too much time, and lost too many queens in testing this matter to resign quietly the claim of having sent out the first queen that ever crossed the Atlantic alive by mail, though Mr. Doolittle and Mr. Cameron doubtless supposed, at the time they wrote, that theirs was really the first.

Munich, Germany, Nov. 8, 1883.

For the American Bee Journal.

Bee-Keeping in Cuba.

A. W. OSBURN.

As the sun was hiding itself behind the far-off western horizon on the 18th of last month, we dropped our anchor in the snug little harbor at Havana, and the staunch sea-craft, the steamship Niagara was at rest. Night shut down upon us, for the first time, in a tropical country.

We left New York on the 13th with 100 colonies of bees, with a complete outfit to begin bee-keeping in Cuba. J. and P. Casanova furnishing the capital for the outfit, myself to furnish what assistance I could to place the enterprise on a working basis, and it is to be the first apiary established on this island, managed after the modern American style.

Our bees stood the voyage well, although they were rolled and tumbled for five days and nights, and many times had more than they wanted of salt water, for they were stored on the second deck, and when the old ship could no longer stand erect, she would lay over on her side for a rest; then the bees would be compelled to take a bath whether they wished it or not.

On the 20th we arrived at this place, and were able to release our bees. All were alive but 3 colonies; in three days more, five empty hives were placed with the three first, making 8 colonies dead, and 92 alive to start off in this land where flowers are so plenty, where the sunshine is perpetual, and where the withering blight of drouth never comes, or Jack Frost makes his appearance.

Although I have been here over a month, I am not able to tell your readers much about the honey flow, only that from the moment the bees were released, there has been no dearth of honey, and, in fact, it would seem there was too much honey, for the bees are literally running the queens out of the hives; as fast as a young bee hatches, they fill the cell with honey. I do not know that the queens fully realize that in November they are expected to keep their hives full of brood. But the bees are getting sick of this kind of work, and are superseding many of the queens.

The old Cubians tell us that this honey flow begins the first of this month, and lasts until February or the first of March (only think of the best honey flow coming in winter and lasting all winter). To you, in the North, it will seem like a dream, when you are huddling around your hard coal stoves to keep warm, and your bees are either chaff-packed outdoors, or stowed away in some underground cellar to keep them from freezing, you can hardly realize that here in Cuba we have our bees under sheds to protect them from the sun, and every evidence points towards success for the busy little workers.

I am not telling anything that in a few months I shall have to take back. There is one thing I will say, that from what I have seen already, I think the bee-keeper will never see honey flow in Cuba as it flows in the North and in California some times; but still it may. Since I have been here, I think the bees have got the most of the honey from the palm-tree, and they tell us it is in bloom the year around. But at this time they say the "boss" honey plant is opening—that is what they call the bell-flower. It yields honey (they say) in great quantities, and of a rich and delicious flavor. So far, the honey I have tasted has been of fine quality, but a little dark; then, again, some of it is white and clear, and to my taste superior to white clover or basswood.

You probably know the prejudice there is in the Northern markets against the honey that has formerly been shipped from this country, and no wonder, they keep their bees in hollow logs, and when they wish to take surplus, they take long knives (the log is open at either end) and cut the honey out—honey, brood, pollen and all—then the honey is squeezed out, and the remainder made into wax. You can easily imagine how the honey looks, and what the flavor would be under such treatment.

The native bee of Cuba is a Simon pure black; there is no German or half-breed about them. But even with the black bees, and their primitive way of handling them, the time was before the war here in Cuba, when they had lots of honey in this primitive way, and it is reported that in the lower end of the island, one man kept 20,000 colonies, and at the commencement of the war, he sold his bees for \$200,000 in gold. I gave you the above as it was repeated to me, not vouching for its truth. But it is not impossible, in a country where you can breed bees at any time of the year, and where there is no time that they do not get a good living.

During the winter months, they tell me, that it is not uncommon for them to take 15 gallons of honey (which would be about 180 pounds) every 15 days. They "rob" them, and, of course, the bees have new comb to build every time. If they do that, Cuba is not so slow a honey country, and what might we expect when managed in the movable frame hives, and the extractor used to throw the honey out.

One word about the face of the country: 'tis simply beautiful, 'tis grand beyond description, rolling and undulating plains, with small brooks and creeks whose banks are thickly studded over with tropical trees, chief among them is the beautiful palm, and the honey plant or tree. The climate is all any one could wish. This section, the Casanova estate, is high and healthful. Yellow fever is seldom if ever known here. In future letters I will report progress as it is developed.

San Miguel, de Jruco, Cuba, West Indies, Nov. 25, 1883.

For the American Bee Journal.

A Premium List for Bees and Honey.

O. CLUTE.

A good premium list for bees, honey, and bee-keeping implements, which, with necessary local modifications, would serve for state fairs, and other large fairs, ought to be prepared by some of our most experienced bee-keepers. Such a list, carefully prepared, would need only slight modifications for many years, and would serve as a guide to the executive committees of many fairs.

Such a list would help much towards the improvement of bee-keeping all over the country. It would tend to the discouragement of poor methods and poor products, and to the encouragement of good ones. In order to have it of service for next year, such a list ought to be prepared very soon, for the executive committees of most of the state fairs meet sometime in January of each year, and then adopt the premium list for the next fair.

I attended the meeting of the executive committee of the Iowa State Agricultural Society, at its winter meeting in Des Moines, last January, and was courteously asked to prepare a premium list. I did prepare one which was adopted without change, and served very well for the fair last September. I am now requested to prepare a list for submission to the board at its meeting, about the middle of January, 1884. I should like to make the list as acceptable as possible to the majority of Iowa bee-keepers, but I have no way of consulting with them except through the columns of the BEE JOURNAL. I therefore ask the JOURNAL to publish the subjoined list now, in order that it may be read by enterprising bee-keepers in Iowa and other states, in time for them to send me their suggestions and criticisms for its improvement.

All bee-keepers are invited to send to me direct, or to Mr. Newman, for publication in the BEE JOURNAL, if he does not object, their thoughts as to the best premium list. It would be especially profitable if we could hear from Rev. L. L. Langstroth, Mr. W. Z. Hutchinson, Mr. O. O. Poppleton, Prof. Cook, Mr. Doolittle, and other successful bee-keepers. This list has been prepared on a basis of an aggregate amount of \$300 for premiums. I have put comb honey and extracted honey on a par; have classi-

fied honey into "white clover," "linden," and "fall flowers," and have put them all on a par, because there are some sections of the West where the fall honey is the main crop.

In bees, I have offered the highest premium on Italians; have put Syrians and Cyprians on a par, and offered premiums half as great; have offered nothing on blacks. No premiums are offered in this list for the manipulation of bees on the ground, because I am not sure we can have a suitable building. I wish, however, that some of the friends would suggest what such premiums ought to be.

I expect that some of the bee-keepers will criticise my list pretty sharply. Well, friends, pitch in and tear my list all to pieces, on condition that you suggest a better one. What I am after is the best list. I am quite willing that this list of mine shall be knocked into splinters, if from its ruins can be evolved the perfect list. So do not spare your suggestions.

	First Prem.	Second Prem.
Best Ital'n. bees in observatory hive.	\$10 00	5 00
Best Cyp. bees in observatory hive.	5 00	2 50

Best product, comb honey, from one colony of bees and its increase for the year	10 00	5 00
Best method of obtaining comb honey, shown by receptacles in place on the hive	5 00	2 50

O. CLUTE.

Pres. Iowa Bee-Keepers' Ass'n.
Iowa City, Iowa, Dec. 5, 1883.

There will be a meeting of the members of the Piatt County Bee-Keepers' Association, at the office of the Secretary in Monticello, Ill., on Saturday, Dec. 15, 1883, at 10 a. m.

A. T. PIPHER, Sec.

The Bee-Keepers' Association of Central Illinois, will meet in Bloomington, on Jan. 9, 1884. All are cordially invited to attend.

JAS. POINDEXTER, Sec.

Please give notice, through the BEE JOURNAL, that C. F. Muth, of Cincinnati, and A. I. Root, of Medina, will be at the Ohio Bee-Keepers' Convention, which will be held in Columbus, on Jan. 14, 15 and 16, and join in the discussions of various subjects interesting to bee-keepers.

C. M. KINGSBURY, Sec.

The annual meeting of the Cortland Union Bee-Keepers' Association will be held in Cortland, N. Y., on Tuesday, Jan. 8, 1884.

M. C. BEAN, Sec.
McGrawville, N. Y., Nov. 23, 1883.

The Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association, will hold its annual meeting in Temperance Hall, Freeport, Ill., on Jan. 15 and 16, 1884.

J. STEWART, Sec.
Rock City, Ill., Nov. 30, 1883.

SELECTIONS FROM OUR LETTER BOX

Syrian Bees, etc.

In a recent article, Mr. W. Z. Hutchinson said of these bees: "Their admirers tell us, if we use them properly, they will be gentle." I extracted 900 lbs. of honey in one day from them, and did not get a sting, and the only smoker I used was a roll of cotton rags. Can Mr. H. do better with hybrid-Italians? They do ripen their honey well; if any one doubts it, I will send him some honey to prove it. I deny that they will "rear brood as long as there is a drop of honey in the hive." I weighed several of my hives this fall, after they had stopped breeding, and they had from 35 to 40 lbs. of honey in them. Two years ago I had an Italian colony that had cast a large swarm, and was ready to swarm again. The queens were piping. I opened the hive to cut out the queen-cells; I smoked them some. They became so irritated, that half of the colony were after me. I threw down my tools and ran for the woods. In doing so, I ran against a tree and skinned my nose. Talk about "irritable" bees; the Syrians are peaceable by the side of such bees. We have no snow yet, and it is warm and summer like.

Cokato, Minn. FAYETTE LEE.

My Report for 1883.

As I did not make a spring report, perhaps it would not be out of place now. The spring found me with 14 colonies, out of the 18 put in the cellar on Nov. 15, 1882. They all had the dysentery, but when I took them out of the cellar on April 15, 1883. In the spring I traded for one; that made me 15 to start with. The spring started favorably. On May 21 it turned cold and wet, and so continued till the last of June. I continued in June and July. June 19, 45 lbs.; June 20, 51 lbs.; June 29, 106 lbs.; July 7, 176 lbs.; July 10, 100 lbs.; July 18, 122 lbs.; July 19, 163 lbs.; July 29, 51 lbs.; Sept. 3, 123 lbs.; making a total of 937 lbs., and had 286 lbs. of comb honey. They increased to 35, and all are in good condition. I put them in the cellar on Nov. 20. I sold all of my honey at home at 12 cents for extracted, and 17 cents to 20 cents for comb. I have on hand about 200 lbs. of honey. DAVID K. KNOLL.

Salamanca, Ind., Dec. 6, 1883.

Foul Brood.

By request of Wm. B. McCormick, Uniontown, Pa., I give the results through the BEE JOURNAL of an examination of a piece of comb honey sent by him. He says that, last spring, he noticed something which he called chilled brood, in one or more of his hives, but as the trouble seemed to continue during the summer, he concluded the difficulty was due to foul brood. He says: "I lost, last summer, about 20 colonies by it, several just leaving their hives, comb, honey and all, and going off, or trying to get into some other hive. Nearly all the bees in the county seem to be more or less affected in the same way."

* * * A. M. Hewitt, some 12 miles from here, told me he lost every one of his 70 colonies. An affected colony will not work, but lay around idle, and will sometimes kill their queen." Mr. McCormick thinks only the black bees are thus affected; the Italians not suffering. Now, after the closest investigation, I find nothing of the micro-organism to which we suppose foul brood is due. There are, in the comb cells, both living and dead larvae; but the dead ones look altogether different from those killed with the disease called foul brood; their original shape is more nearly retained, the fluids of the body are much more watery—notropy when pulled out—and the odor, though somewhat disagreeable, is characteristically different. What the trouble is I cannot say; but foul brood is not present in the sample received.

Champaign, Ill. T. J. BURRILL.

A Cold, Wet Season.

I commenced the honey season with 50 colonies, but a good many being weak, as we had such a cold and wet spring, they dwindled badly. I had a good flow of honey from white clover, but that was all. I think this was the coldest and wettest summer I ever knew. I now have 83 colonies in winter quarters, in good condition. I have taken 4,023 lbs. of extracted honey, and 950 lbs. of comb honey, and the bees have plenty to winter on.

H. J. SMITH.

Burlington, Wis., Nov. 30, 1883.

My Report for the Year.

On Nov. 20, 1882, I put into winter quarters 16 colonies, in 10-frame Langstroth hives, except a weak one in a 6-frame hive, which starved before spring. Last April I bought 4 colonies, in box hives, making 19 to start this season with. I transferred the four 21 days after the first swarm issued. Honey from the apple bloom was light, owing to the cold, wet weather last spring. I got about half a crop of honey from white clover. The basswood crop was heavy; then came a drouth, followed by an early frost, which made our fall crop light. I took a little over 2,000 pounds of honey, this season (525 being extracted and 1,500 pounds in the comb), nearly all in one-pound sections. My bees increased to 50 colonies. I doubled up some that were weak, and now have 47 packed as last winter, in a

low shed facing the south, covered on top, back and ends with dirt and sod. I pack my hives close together with some straw and chaff over and behind them. When cold weather sets in, I put up a door in front of them, which I can let down in front on days suitable for them to fly out. The brown German bees gave larger yields of honey than the Italians. I use what some of our advanced apiarists call rattle-traps; that is an outside cover over my section racks, which I find a great advantage in keeping the hot sun from them; they are also an advantage in cool nights. Oh, yes, I use an inch strip of glass in each side of my section-rack, which saves a great deal of time, peeking in at the top, when I have them tiered up 2 and 3 sections deep. I have no trouble in getting my honey sealed over next to the glass.

R. A. CALVIN.

Hartford, Mich., Dec. 3, 1883.

Italians and Hybrids.

I commenced last spring's work with 10 colonies of bees; they increased to 23, and I bought 8 extra colonies this fall, which make a good stock to start with next spring. Last winter I wintered 2 colonies in a very damp vapory cellar with the thermometer averaging from 40° to 45° Fahr. I gave them lower ventilation about 2 square inches in each hive; one colony was an Italian, and the other a hybrid. The hybrids kept up a continual hum all winter, but the Italians remained as still as death. When I thumped the hive they responded with a sharp hum; then all would be quiet in half a minute. But the hybrids consumed about double the honey that the Italians did, and the colonies were about equal in numbers. The hybrids were in a Quinby hive, while the others were in a Langstroth hive, and they both came out healthy in the spring. The only reason I can give for the extra amount of honey consumed by the hybrids is, that they were not in as warm a hive as the Italians, which was made of inch lumber, while the Quinby hive was made of half-inch lumber.

CHARLES NORRIS.

Traverse City, Mich., Nov. 28, 1883.

My Favorite Feeder, etc.

The feeder I use is, essentially, a broad frame with boards at the sides extending to within an inch of the top, with bottom and sides made watertight. The end pieces are of inch boards; the sides, bottom and top are of one-half-inch plank undressed, and just as left by the saw. I make the joints water-tight by a layer of white lead, spread in before nailing together. The feeder is just the size and shape of an ordinary broad frame, and holds about one gallon of syrup. It hangs in the hive just as an ordinary frame. In it I place a float made one-half inch smaller than the inside of the feeder; it is simply a section box strip, trimmed, till it floats loosely in the feeder. I fill this, hang it in the hive, and the feeding is done, with no drowned bees, and not the slightest danger of robbing. I began the season

with 11 colonies; I used 4 of them for experiments and queen rearing. The remaining seven were run for comb honey, of which I obtained 560 lbs.; 450 from white clover, a few pounds from linden, and the rest fall honey from various sources. I have sold \$75 worth of bees and queens, and have 29 colonies remaining, as the result of the years' increase. I had to feed a few of my queen-rearing colonies; the rest had plenty of stores.

L. C. JOHNSON.

Fountain City, Ind., Dec. 3, 1883.

Ten Dollars a Colony net Profit.

I commenced the season with 20 colonies of black bees, increased to 57, and obtained \$180 worth of comb and extracted honey, besides selling 12 colonies at \$5 each. The receipts were:

Honey.....	\$180 00
Bees.....	60 00

Total.....	240 00
------------	--------

Expense for extractor.....	\$11 50
Foundation.....	8 40
Lumber.....	20 00

Total.....	39 90
------------	-------

Leaving a net profit of \$200.

W. G. HAYEN.

Pleasant Mound, Ill., Dec. 3, 1883.

Bee Meeting at Fayette, Iowa.

Our bee-keepers' meeting held at Fayette, Iowa, was quite well attended, and considerable interest manifested, and an organization effected. A. H. Loomis, of Clermont, President; V. Whiting, of Waucoma, Vice-President; B. F. Little, of Brush Creek, Secretary; and H. Randall, of Randalia, Treasurer. We adopted a constitution and by-laws. There were hives, honey, both comb and extracted, extractors, foundation machines, smokers, uncapping knives, etc., etc., on exhibition; all of which attracted much attention, and elicited considerable discussion. All in all, we felt as though it was a most interesting and profitable meeting, and I think we have established it upon a pretty sure foundation. Of course it was but a beginning, and somewhat crude, but we hope to improve with age, and be enable sometime to call in outsiders, practical apiarists, to discuss the *pros* and *cons* with us, and address the meeting on "The Blessed Bees." Most of our bees hereabouts go into winter quarters in a weak condition. The long cold fall, without any bee pasturage, leaves them in a bad condition to hope for strong colonies next spring.

A. H. LOOMIS.

Clermont, Iowa, Nov. 24, 1883.

More Honey than I Expected.

The weather has been beautiful for the past few weeks, very much like spring; bees flying quite often, and their humming sounds like the busy time of the year. My honey crop was over 1,000 lbs. instead of 600 lbs., for which I am proportionately happy.

B. H. HOLZ.

Adel, Iowa, Dec. 6, 1883.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Make all Postal Money Orders and Postal Notes payable at the Madison St. Station, Chicago, Ill.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper, shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter, on your label, notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a *continual* statement of account.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

Our New List of Premiums.

Getting up Clubs for 1884.

To increase the number of readers of the BEE JOURNAL, we believe, will aid progressive bee-culture and help to elevate the pursuit. We, therefore, offer the following premiums for getting up clubs:

While no subscription to the BEE JOURNAL will be taken for less than the regular advertised prices (viz.: Weekly, \$2.00; Monthly, \$1.00),—any one getting up a club of two copies, or more, may select from "OUR BOOK LIST" anything therein named, to the amount of 15 cents for every dollar they send *direct to this office*, to pay them for the trouble of getting up the club; and these books will be sent, postpaid, to any address desired.

For a club of 3 Weekly or 6 Monthly and \$6.00, we will make an *additional* present of a Pocket Dictionary, bound in cloth, containing 320 pages.

For a club of 5 Weekly or 10 Monthly, (or a mixed club of both,) with \$10, we will, in addition to the 15 per cent, present a copy of the AMERICAN "POPULAR" DICTIONARY, comprising every word in the English language that enters into speech or writing; it contains 32,000 words and phrases, 670 illustrations and 512 pages; it is nicely bound in cloth, and will be sent by mail, postpaid, to any address desired.

For a club of \$20, for 10 Weeklies, or an equivalent in Monthlies, we will present, besides the 15 per cent, in books, a tested Italian queen, by mail, postpaid.

Subscriptions for two or more years for one person, will count the same as each year for a different person.

For a club of 100 Weekly (or its equivalent in Monthlies), with \$200, we will send a Magnificent Organ worth \$150. See description on page 614 of the Weekly for Nov. 28, 1883.

Do not let your numbers of the BEE JOURNAL for 1883 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

It must be understood that, should an advertiser desire to cancel an unexpired contract, he can do so only by paying regular rates for the number of insertions his advertisement has had.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones.

When writing to this office on business, our correspondents should not write anything for publication on the same sheet of paper, unless it can be torn apart without interfering with either portion of the letter. The editorial and business departments are separate and distinct, and when the business is mixed up with items for publication it often causes confusion. They may both be sent in one envelope but on separate pieces of paper.

Bee Pasturage a Necessity.—We have issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for ten cents.

Emerson Binders—made especially for the BEE JOURNAL, are lettered in gold on the back, and make a very convenient way of preserving the BEE JOURNAL as fast as received. They will be sent, post-paid, for 75 cents, for the Weekly; or for the Monthly, 50 cents. They cannot be sent by mail to Canada.

We carefully mail the BEE JOURNAL to every subscriber, but should any be lost in the mails we will cheerfully send another, if notified before all the edition is exhausted.

Sample Copies of the AMERICAN BEE JOURNAL will be sent *free* to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

Articles for publication must be written on a separate piece of paper from items of business.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey. instructions on the exhibition of bees and honey at Fairs, etc. This is a new 10 cent pamphlet, of 32 pages.

Speak a word for the BEE JOURNAL to neighbors who keep bees, and send on at least one new subscription with your own? Our premium, "Bees and Honey," in cloth, for one new subscriber to the Weekly, or two for the Monthly, besides your own subscription to either edition, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

We need the numbers of the BEE JOURNAL for August, 1866, and April, 1876. Any one having them to spare, are requested to send us a Postal Card. We will give 25 cents for each. Do not send them without writing, for we want only one of each; and, if we are not already supplied, we will take them.

A correspondent asks if any one may select a Binder for the BEE JOURNAL among the books given as Premiums for getting subscribers we reply, yes; any book or binder we keep for sale, may be selected by those who get up clubs.

To all new subscribers for the Weekly BEE JOURNAL who send us \$2.00 for 1884, we will send the remainder of this year free, from the time the subscription is received. So, the sooner they subscribe, the more numbers they will get free.

Advertisers' Opinion.

The queen business is *rushing*, and we think the BEE JOURNAL deserves much credit as an advertising medium.
E. A. THOMAS & Co.
Coleraine, Mass., July 18, 1883.

THE BRITISH BEE JOURNAL AND BEE-KEEPER'S ADVISER.

The BRITISH BEE JOURNAL is NOW published SEMI-MONTHLY, at Seven Shillings, per annum, and contains the best practical information for the time being, showing what to do, and when and how to do it. Rev. H. B. PEELE, Editor.

We send the Weekly AMERICAN BEE JOURNAL and the British Bee Journal, both for \$3.00 a year.

OLDEST BEE PAPER
IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED
IN 1861

DEVOTED TO SCIENTIFIC BEE-CULTURE AND HONEY PRODUCTION.

Vol. XIX.

Chicago, Ill., December 26, 1883.

No. 52.

THE WEEKLY EDITION

THE AMERICAN BEE JOURNAL

PUBLISHED BY

THOMAS C. NEWMAN,

EDITOR AND PROPRIETOR.

925 WEST MADISON ST., CHICAGO, ILL.

Weekly, \$2 a year; Monthly, \$1.

PREMIUM.—Any one sending one new subscription for the Weekly, or two for the Monthly, for one year, besides their own subscription for a year for the Weekly, will be entitled to a copy of "Bees and Honey," bound in cloth.

The receipt for money sent us will be given on the address label on every paper. If not given in two weeks after sending the money, write us a Postal card, for something must be wrong about it.

Any person sending a club of six, is entitled to an extra copy (like the club), sent to any address desired. Sample copies furnished free.

Papers are stopped at the expiration of the time paid for, unless requested to be continued.

FOREIGN POSTAGE, EXTRA:

To Europe—Weekly, 50 cents; Monthly, 12 cents.
To Australia—Weekly, \$1; Monthly, 24 cents.

George Neighbour & Sons, London, England, are our authorized agents for Europe.

Entered at the Chicago P. O. as Second Class Matter.

ADVERTISING RATES.

20 cents per line of space, each insertion,

For either the Weekly or Monthly Editions.

A line of this type will contain about 8 words; TWELVE lines will occupy ONE-INCH of space. Transient Advertisements payable in advance. Editorial Notices, 50 cents per line.

Advertisements may be inserted one, two or four times a month, if so ordered, at 20 cents per line, of space, for each insertion.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,

925 West Madison Street., Chicago, Ill.

The contents of this number being included in the general indexes to the volume, found on pages 675 to 678, we omit the usual index here.

THIS NUMBER will complete the volume of the Weekly BEE JOURNAL for 1883. We would respectfully request all our present subscribers to renew at once for 1884. By sending on the subscriptions at once, it will save us much extra labor in taking the names from our mail list, which is kept in type, and then replacing them again in a week or two. It will also prevent the loss of any copies of the JOURNAL, and be an advantage all around. If any find it inconvenient to send the \$2.00 now, send us a postal card requesting us to continue sending it along, and then the remittance may follow in a week or two afterwards.

The Monthly Bee Journal and any of the above, \$1 less than the figures in the last column.

Speak a word for the BEE JOURNAL to neighbors who keep bees, and send on at least one new subscription with your own? Our premium, "Bees and Honey," in cloth, for one new subscriber to the Weekly, or two for the Monthly, besides your own subscription to either edition, will pay you for your trouble, besides having the satisfaction of knowing that you have aided the BEE JOURNAL to a new subscriber, and progressive apiculture to another devotee.

To give away a copy of "Honey as Food and Medicine" to every one who buys a package of honey, will sell almost any quantity of it.

Advertisements.

THE AMERICAN BEE JOURNAL is the oldest Bee Paper in America, and has a large circulation in every State, Territory and Province, among farmers, mechanics, professional and business men, and is, therefore, the best advertising medium.

DADANT'S HONEY CROP!

Our crop being very large, we offer **THIRTY THOUSAND POUNDS** of extracted Honey

FOR SALE

at REASONABLE PRICES. We have both clover and fall honey. Samples sent on receipt of stamps to pay postage. The honey can be delivered in any shape to suit purchasers.

Send **15c.** for our 24-page Pamphlet on Harvesting, Handling and Marketing extracted honey.

CHAS. DADANT & SON,

5AB1y HAMILTON, Hancock Co., ILL.

1876. CROWN 1882.

The best arranged HIVE for all purposes in existence. Took first premium at St. Louis Fair in 1882 and 1883 over all competitors. Descriptive Circular sent free to all on application.

Address, **ELVIN ARMSTRONG,**
Prop'r. of the Crown Bee Hive Factory and Apiary,
JERSEYVILLE, ILL.

DADANT'S FOUNDATION

From JAMES HEDDON, July 27th, 1883. — Your Foundation is certainly the nicest and best handled of any I have seen on the market. It is the only foundation true to sample I have ever received.

From JAMES HEDDON, Aug. 10th, 1883. — I will contract for 2,000 pounds of foundation for next season on the terms of your letter.

From A. H. NEWMAN, Aug. 24th, 1883. — Book my order for 5,000 pounds for spring delivery.

From C. F. MUTH, Sept. 6th, 1883. — All of your shipments of foundation during the season were sold on the day of their arrival.

Dealers, send in your orders for next spring while wax is cheaper, and save trouble and money.

CHAS. DADANT & SON,

5AB1y Hamilton, Hancock co., Ill.

MANUFACTORY FOR HIVES, SECTIONS, &c.

I am now prepared to supply dealers and consumers with

Hives, Sections, Broad Frames, Shipping Crates, etc.,

all kinds. I make a specialty of LANGSTROTH AND MODERN HIVES. Correspondence with supply dealers solicited. My Sections are all made from Poplar. Address,

49A4t&1Cf 12Btf DUNDEE, Kane Co., ILL.

BOOKS!

Sent by mail, on receipt of price, by

THOMAS G. NEWMAN,

925 West Madison Street, CHICAGO, ILL.

On dozen or half-dozen lots of one kind, we allow 25 per cent. discount, and prepay postage. Special rates, on larger quantities, given upon application.

Dzierzon's Rational Bee-Keeping.—A Translation of the Masterpiece of that most celebrated German authority, by H. Dieck and S. Stutterd, and edited, with notes, by Charles N. Abbott, *Ex-editor of the "British Bee Journal."* Dr. Dzierzon is one of the greatest living authorities on Bee Culture. To him and the Baron of Berlepsch we are indebted for much that is known of scientific bee culture. Concerning this book, Prof. Cook says: "As the work of one of the great masters, the Langstroth of Germany, it can but find a warm welcome on this side of the Atlantic." Mr. A. J. Root says of it: "Old father Dzierzon has probably made greater strides in scientific apiculture than any one man... For real scientific value, it would well repay any beekeeper whose attention is at all inclined to scientific research, to purchase a copy. Cloth, \$2.

Queen-Rearing, by Henry Alley.—A full and detailed account of TWENTY-THREE years' experience in rearing queen bees. The cheapest, easiest and best way to raise queens. Never before published. Price, \$1.00.

Bee-Keeper's Guide for Cook's Manual of the Apiary.—This Manual is elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman. Fourth Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains two pages, is profusely illustrated. Price, bound in cloth, 75c.; in paper covers, 50c., postpaid.

Honey, as Food and Medicine, by Thomas G. Newman. — This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc.; and Honey as Medicine, with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 5c.; per dozen, 50c.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. — This is a chapter from "Bees and Honey." Price 10c.

Swarming, Dividing and Feeding Bees.—Hints to Beginners, by Thomas G. Newman. This is a chapter from "Bees and Honey." Price, 5c.

Bee Pasturage a Necessity, by Thomas G. Newman.—Giving advanced views on this important subject, with suggestions what to plant, and when and how to sow. Price, 10c.

Bees in Winter, with instructions about Chaff-Packing, Cellars and Bee Houses, by Thomas G. Newman. — This is a chapter from "Bees and Honey." Price, 5c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages 50c.

Scribner's Lumber and Log Book.—Most complete book of its kind published. Gives measurement of all kinds of lumber, logs, and planks by Doyle's Rule, cubical contents of saws and round timber, staves and heading bolt tables, wages, rent, board capacity of cisterns, cordwood tables, interests, etc. Standard book throughout United States & Canada. Price 35 c. postpaid.

Fisher's Grain Tables for Farmers, etc.—192 pages, pocket form; full of useful tables for casting up grain, produce, hay; cost of pork, interest, wages tables, wood measure, ready reckoner, plowing tables and more miscellaneous matter and useful tables for farmers and others than any similar book ever published. 40 cents.

Moore's Universal Assistant, and Complete Mechanic, contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer, and Business Man. Gives 20,000 Items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Gilders, Metal and Wood Workers of every kind.

The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

Kendall's Horse Book.—No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Price 25c. for either the English or German editions.

Quinby's New Bee-Keeping, by L. C. Root.—The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject. \$1.50.

The Hive I Use.—Being a description of the hive used by O. M. Doolittle. Price, 5c.

Novice's ABC of Bee-Culture, by A. J. Root.—This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25.

King's Bee-Keepers' Text-Book, by A. J. King.—This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee.—This is a standard scientific work. Price, \$2.

Blessed Bees, by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Foul Brood; its origin, development and cure. By Albert R. Kohke. Price, 25c.

Extracted Honey; Harvesting, Handling and Marketing.—A 24-page pamphlet, by Ch. & C. P. Dadant, giving in detail the methods and management adopted in their apiary. 15c.

Practical Hints to Bee-Keepers, by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Dzierzon Theory—presents the fundamental principles of bee-culture, and publishes the facts and arguments to demonstrate them. 15c.

Apiary Register, for SYSTEMATIC WORK in the APIARY.—The larger one can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book. Prices: For 50 colonies, \$1.00; for 100 colonies, \$1.50; for 200 colonies, \$2.00.

Deutsche Buecher, Ueber Bienenzücht.

Bienen Kultur, oder erfolgreiche Behandlung der Bienen, von Thos. G. Newman. Dieses Pamphlet enthält Belehrungen über folgende Gegenstände — Derlichkeit des Bienenstandes — Honig pflanzen — Erziehung der Königin — Füttern — Schwärmen — Ableger — Versetzen — Italienisieren — Züchter von Königinnen — Ausziehen — Bienen behandeln und beruhigen; weiter enthält es ein Kapitel, worin die neueste Methode für die Herrichtung des Honigs für den Handel beschreiben ist. Preis 40 Cents.

Honig als Nahrung und Medizin—von Thomas G. Newman. Dieses enthält eine klare darstellend über Bienen und Honig des Alterthums; die Beschaffenheit, Qualität, Quellen und Zubereitung des Honigs für den Handel; Honig als Nahrungsmittel, angebend wie man Honigkuchen, Formförmelchen, Puddings, Schaumkonfekt, Weine, u. s. w. zubereiten kann; ferner Honig als Medizin mit vielen Rezepten. Es ist für den Consumenten bestimmt, und sollte vieltausendfältig über das ganze Land verbreitet werden. Preis 6 Cents.

Das Pferd und seine Krankheiten—Von B. J. Kendall, M. D., enthaltend ein alphabetisch geordnetes Verzeichniß der verschiedenen Pferdekrankheiten, sammt den Ursachen, Symptomen und der richtigen Behandlung derselben; ferner, eine Sammlung werthvoller Recepte. Preis 25 Cents.

THOMAS G. NEWMAN,

925 West Madison St., CHICAGO, ILL.

Weekly Bee Journal,

DEVOTED TO THE INTERESTS OF THE PRODUCERS OF HONEY.

VOL. XIX.

CHICAGO, ILL., DECEMBER 26, 1883.

No. 52.

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR.

☞ We point with pride to the copious Indexes contained in this paper. They will be of untold value to those who bind the JOURNAL, or those who use Emerson Binders in which to keep the volume.

☞ "Fifty-two dividends a year from \$2 invested." That is what every one will receive who subscribes for the Weekly BEE JOURNAL.

☞ The Rev. S. L. Stiver, of Bunker Hill, Ills., asks: "Will pure honey granulate? and if so, is it as nutritious and wholesome as the ungranulated?" Yes; nearly all pure honey will granulate on the approach of cold weather or before, and is not only as nutritious, but it is preferred by many for table use and medicinal purposes.

☞ As the reading season has come with the long winter evenings, it is just the time to read the various books on Bee-keeping. When renewing your subscriptions will be a good time to get a supply of such literature. See our club rate on Books with the BEE JOURNAL on the first page of this paper.

☞ We have received the Catalogue and Price List of Mr. Elvin Armstrong, Jerseyville, Ill., for 1884. The Crown bee hive and supplies generally.

☞ We can supply photographs of Rev. L. L. Langstroth, the Baron of Berlepsch, or Dzierzon, at 25 cts. each.

☞ For \$2.75 we will supply the Weekly BEE JOURNAL one year, and Dzierzon's Rational Bee-Keeping, in paper covers; or in cloth for \$3.00.

The Volume for 1883 is Finished.

With this number of the Weekly BEE JOURNAL, the volume for 1883 is complete! The work on it is done—the volume closed—the year ended—another "star" added to the galaxy of the bright luminaries of its existence!

The success of the Weekly BEE JOURNAL during the past years of its existence, has far exceeded the expectations of its publisher, and shows that the time had fully come when its existence was a public necessity. Who among progressive apiarists would now consent for a moment to go back again to a monthly? Echo asks, *Who?* and the echo reverberates the only reply.

It is a source of much congratulation to its friends, as well as its publisher, that it enjoys a reputation for reliability and integrity, of which but few of the publications of the world can boast.

We are quite willing to submit to the verdict of its ten thousand readers, as to how well it has sustained the promises made a year ago, that it would "continue to lead in all the qualities of our ever-advancing art, and maintain its high position as the most enterprising Bee Paper of the World." The thousands who have already volunteered their appreciation during the year, and testified of its practical value by their continued patronage, and those who now are showing their esteem by promptly renewing their subscriptions for the coming year (and with these substantial approvals send words of encouragement); all stimulate us to further diligence in the prosecution of our life work. Its record, character, power and usefulness in the past, is its guarantee for the future.

We have already engaged an army of regular correspondents of the BEE JOURNAL for the year 1884, comprising the best apicultural writers of the present age, and many of the

most practical and successful apiarists of the world.

As heretofore, the BEE JOURNAL will continue to be the medium for the promulgation of the best thoughts of the most advanced bee-keepers of the age—keeping abreast of the highest progress, favoring the freest discussion of all points of interest in apiculture, advancing progressive ideas and the newest practical conceptions and improvements.

Amid all the rush of correspondence at this season of the year, we will pause a moment to wish all our readers

A MERRY CHRISTMAS,

AND

A HAPPY NEW YEAR!

Honey Crop of France and America.

Mr. Jas. McKnight, of Capistrano, Cal., writes us as follows:

A friend of mine, Mr. Louis Dartigues, of this place, asked me to guess how many colonies of bees there were in France. Of course I could not do so. Judge of my astonishment when he handed me the enclosed strip taken from a French paper:

Colonies, 1,971,365; honey, 9,948,642 kilos.; wax, 2,845,749 kilos.; value of honey, 14,945,835 francs; value of wax, 8,752,299 francs; total, 23,698,134 francs.

Translated to our figures it is about as follows: Colonies, 1,971,365; honey, 21,887,000 lbs.; wax, 6,260,600 lbs.; value of honey, \$2,989,167; value of wax, \$1,750,460; total value, \$1,749,627.

As we sometimes hear that the United States is the largest honey-producing country in the world, I would like to know what the figures of the last census gives, or how does it compare with the above?

The last census reports have not yet been published, but it is estimated that there are in the United States and the Dominion of Canada, about six millions of colonies of bees, and the honey crop is valued at about thirty millions of dollars. The wax product is valued at about two millions of dollars. Modern management produces less wax than with the old style of destroying the bees for the honey and wax.

CORRESPONDENCE

For the American Bee Journal.

Michigan State Convention.

W. Z. HUTCHINSON.

SECOND DAY.

The meeting was called to order at 9 a. m. by President Cook, and then the Convention proceeded to discuss the "Selling of Honey."

C. F. Muth said that he had induced many manufacturers of tobacco, of cakes and cookies, of pickles, as well as packers of pork, to use honey in place of other sweets. If we keep our honey pure, there will be no trouble in disposing of it. He exhibited some excellent cookies or buns, in the manufacture of which, honey was used.

A. D. Benham: A confectioner in our town took my entire crop of 1,000 pounds of extracted honey to use in making cookies. He also had samples which were very much like those brought by Mr. Muth.

B. Salisbury spoke of the benefits of honey in pulmonary diseases.

Rev. L. L. Langstroth had a dear friend that was apparently near death's door from consumption, who was restored to health by small but frequent doses of honey. He considered basswood honey the best for lung diseases.

"Is Bee-Keeping Healthful?" was next discussed.

Dr. Mason said, no; bee-keeping is not healthful. My hands, at times hang almost helpless from the effects of bee poison. Almost every fall I am nearly disabled from the effects of the poison. If I keep away from the bees I am all right.

C. F. Muth: Get better-natured bees. Dr. Mason: My bees are as good-natured as most bees, but bees delight in stinging me. While at Mr. Muth's apiary I was stung three times, but Mr. Muth knew nothing about it.

Rev. L. L. Langstroth: When I commenced bee-keeping, a sting caused much swelling, but in time this trouble passed away. Several years passed, during which I handled no bees, and when I again attempted it, I found myself more susceptible to the poison than ever, but by continuing to work with the bees, disregarding the stings, my former indifference returned.

D. A. Jones: When a hive is opened every frame should be moved along a little, and the whole hive disturbed before the first frame is lifted out, this disorganizes the whole of the bees, and starts them to eating honey, and the danger from stings is lessened.

M. H. Hunt: Honey is an excellent remedy, and is always handy.

Mr. Sheldon: Bee stings have cured rheumatism for me.

Dr. Mason: Bee stings never helped my rheumatism.

D. A. Jones: I have cured rheumatism and neuralgia, for the time being,

with bee stings, but the next day it returned. By singing the hairs from the back of the hand and wrist, many stings will be prevented. The bees catch their feet in the hairs, if left on, become irritated and sting.

Dr. Rulison: Chloroform is an excellent remedy for stings.

Mr. Millard: I am afflicted with eruptions and boils, caused by bee poison.

Your humble servant (W. Z. H.) had in his mind the case of Mr. James Heddon, who suffers so much from the effect of bee poison as to be almost entirely prevented from handling bees, but, as many others wanted to talk, he said nothing.

"Exhibitions at the State Fair," was then discussed. Secretary Cutting gave a detailed report of his meeting the officers of the State Agricultural Society, inducing them to increase the premium list and put up a building expressly for the apianian department. He then read the following upon the importance of making exhibits at Fairs:

Exhibitions properly conducted are educational institutions. I think it is conceded that to create a demand for anything is to bring it before the public in some form where the masses can be educated to its uses, and I know of no place where anything can be brought before the public, and its uses explained, as well as at State and County Fairs.

Where can you place honey to reach the eye of the consumer as well as at large exhibitions? Honey placed on exhibition at fairs, is seen by thousands every day; and when put up attractively, to please the eye, it creates a demand.

How often the exhibitor hears this remark: "I did not think of buying honey when I came here, but it looks so nice that I must take some home." If you put honey in a box, and put up notices all around, saying that you have honey for sale, and I dare say you will not sell a box a day; while the exhibitor opposite, who has a large exhibit, put up in an attractive manner, will sell large quantities every day.

You must be ready to explain away all existing prejudice, for you will find such every hour in the day, that seems foolish to you, because you have been educated to know better. I well remember one little incident that happened at our last State Fair. A party of ladies came along, when one asked the question: "What is that machine for?" and the answer was, to make comb foundation for the bees to work on—at the same time showing them a fine specimen. The lady turned to the party she was with, and exclaimed: "There, didn't I tell you that honey was adulterated, for here is the very machine to make the comb, and there is the machine to fill it" (referring to an extractor). It took no small amount of talk to break down the prejudice.

To the supply dealer exhibitions are a fine thing. Bee-keepers know that there will be placed on exhibition a large collection of implements and supplies of all kinds, and they go to

the fair to see what is new and what they can learn, and if you have a good line of supplies you will get many an order that you would not have in any other way.

Men get different ideas from what they read and what they see. You may describe an article, and the party you wish to reach does not get your idea of it, but the moment he "sees the article" it is different; he does not hesitate to buy it. You must bring your goods before the consumer if you expect to dispose of them.

Another important feature that is left out at our exhibitions, is lady bee-keepers. A few lady bee-keepers would help exhibitions greatly. They can arrange an exhibit much more tastefully than men, and the lady visitors will stop and talk with lady exhibitors much sooner than with men. Any woman can exert a great moral influence and render our exhibitions much more attractive.

I would earnestly appeal to every bee-keeper to come out next fall at our State Fair and make a grand exhibition. Do not hold back because you have not much to show; every one helps. Last year one man came with a single bee hive and received the first premium.

The Agricultural Society does not want to see one man fill the building, but it wants all to come. A building will be provided large enough to accommodate all. In no other way can you make the sale of honey so great as to make a fine exhibit at fairs all over the land. So I will say again: "Come one and all; bring what you can, and let us show our Mother Country that we, too, can have a great bee and honey show."

A. J. Cook: When I went to the State Fair, the President did not wait for me to come through the yard, but came out to meet me, and said that he was proud of the exhibit in the apianian department.

D. A. Jones said that honey-shows increased its sale wonderfully. Two thousand two-ounce packages of honey were sold at 5 cents each, at our fair. These packages gave people a taste, inducing them to buy larger packages. One dealer bought them to give as Christmas advertisement. Honey-producers should not neglect this great educator of the people.

M. H. Hunt: I sold all my honey at the fair. Mr. Hutchinson sold some, and might have sold all of it if he had not held it above market price.

S. T. Pettit: Candied honey should be exhibited at fairs. Most bee-keepers exhibit their honey in the liquid form; purchasers carry it home in that form, and when it crystallizes they think something must be wrong, and fear that it is adulterated.

To revise the State Fair premium list, and urge its adoption by the officers of the Agricultural Society, the following were appointed as a committee: H. D. Cutting, D. A. Jones, Dr. Mason, Dr. Kazartee and C. F. Muth.

The President's address was then read by Prof. Cook, and was enthusiastically received. It was as follows:

THE OUTLOOK OF APICULTURE.

Brothers of the apiary, ladies and gentlemen:—

The Constitution of our Association makes it incumbent upon me to present the annual address by virtue of my office as President of the Society. In casting about for a theme suitable to this occasion, I can find nothing I deem more worthy than "The Outlook of Apiculture."

Before commencing a survey of the present status of our art, I pause for a moment to speak of an event which is of deepest interest to us all. Need I say I refer to the presence among us of our honored and revered friend and benefactor, whose invention alone made possible the mighty progress of our art; whose rare gift as an experimentalist, scholarly attainments and surpassing gift as a writer, gave to us the greatest work ever written on apiculture; whose grand character, transparent ingenuousness, child-like simplicity, and retiring modesty, teach us so graphically what the Christ spirit can do for man; whose great heart ever moved by the broadest charity, made him to bless, even those whose curses he bitterly felt. To know such an one, to look upon him, to grasp his hand, to hear his words of wisdom, bringing to us the treasures of a mind stored with the richest truths, and of a heart, too great to feel malice; and so large that it reaches out to aid even the least of us, all of this is an experience which we Michigan bee-keepers appreciate to-day. How greatly we are honored, we cannot now find words to express; but in all our future we shall remember this event, as realizing to us, a hope which we had never expected to see fulfilled.

A few years ago the cynics of our brotherhood told us that conventions were the enemies of our art, that they were worse than useless, and that to stimulate the growth of apiculture was to use the suicide's dagger. Now it is rare indeed to find a man so narrow as to declaim against association. While time has shown that with bee-keeping, as with every other business, increased supply brings a much greater increase in demand, which is further made potential for good, by bringing the increased energy and intelligence which numbers are sure to give. The business that booms, is the one that has among its patrons the talent, the fact, the energy and the genius of the country. Without conventions, we could not have inaugurated, and made successful our splendid exhibitions, which are sure to foster our art as few other things can. Those States whose conventions are ablest, and most frequent, are ahead. It is always so, with every art and at all times. County and District societies should send delegates to the State association, and the State to the Inter-State and National. Thus concerted action will be made possible; thus the thought and methods of the most progressive will become the property of the many. To be sure, we have our excellent periodicals, but they are only possible, as association inspires bee-keeping; and, good as it seems and is to get the thoughts and methods of

our able apiarists through the press, it is not like personal intercourse, and word of mouth. Conventions are a powerful educator. No single bee-keeper becomes abler and better prepared to do his work well, without benefiting the whole fraternity.

We increase our art, only as success shows it worthy. I may praise our business with a voice that would do honor to an auctioneer, yet that will influence little unless my neighbors see evidence that the almighty dollar puts in an appearance. Those who are energetic, willing to work, intelligent and willing and eager to learn, observing, persevering and attentive to their work, will rarely ever fail in apiculture. Those who lack these qualities will be left behind before they get far enough to meet great loss; so little mischief is wrought even if some are induced to adopt this business, and because they lack the elements of success, fail. Usually they gain enough added intelligence to more than pay for the time and capital expended.

Another fallacy, as I think, which some few of our apiarists are loudly proclaiming, is that apiculture is only for the specialist. Why, gentlemen, our brothers in horticulture and agriculture are free to admit that they owe more, in the way of real progress and advancement to amateurs than to specialists. I know that apiculture is no exception. Our honored guest was an amateur when he conferred the greatest boon upon our art. Long, Demaree, Clute, and a host of others of our best bee-keepers, are amateurs. I am free to say that three-fourths of the honey product of our State is produced by men with whom apiculture is only an avocation. I can name a score of bee-keepers, whom I know personally, who are farmers, lawyers, doctors, who keep hundreds of colonies of bees, and many of whom, not only get large returns of honey, but winter each and every year with entire success. When our specialists are all equally successful, then they may cry hold! enough! with more justice.

An indication that the new recruits in apiculture will exalt rather than degrade the business, is seen in the fact that many are calling for instruction in this line. Few studies at our Agricultural College win more earnest study and real enthusiasm than does entomology, which embraces quite thorough instruction in apiculture. Last year we had a student from England, and this year one from Texas, who came especially for the bee-culture. The fact that Messrs. Jones, Heddon and Clute have respectable classes, shows that there is a call for more knowledge. We can but wish God-speed to all of these gentlemen in their efforts. Special training is most desirable to the would-be apiarist. To be with such efficient bee-keepers for a season will give a vantage ground that can hardly be appreciated till enjoyed. The practical apiarist will be more proficient if he has had the science of entomology and physiology, and other cognate studies, but if he cannot because of age or circumstance take so much time, let him by all means study and work for a season

with some good apiarist. Such a course will never be regretted.

The past season has shown that we can procure nearly as much honey in small as larger sections. It would also seem that with the proper arrangement and care, we have no need of separators. That there will ever be call for sections smaller than $4\frac{1}{2}$ inches square, sufficient to warrant their adoption, at the added expense in time and money which they demand, I much doubt. I secured quite an amount of honey the past season in the small sections—half-pound sections—but I found those who bought it, thought these smaller sections in no wise preferable to the common one-pound section. It is reported that Mr. Heddon is going to adopt the smaller size exclusively another season. It may pay him to do so; but for the most of us, I think, we shall be wise to adhere to the one and two-pound sections.

Another question in which we all take a deep interest, is the "New Bees." I have had no experience with the Cyprian bees, but I think more and more of the Syrian. I find no trouble to handle them, and take my large class of students, new to the business, right into the apiary. These 30 or 40 students daily manipulate the bees, doing everything that the bee-keeper ever needs to do, and rarely ever get stung. I find that the comb honey of the Syrians is excellent, that the bees go readily into the sections. We did not get all our sections so that they could be crated without the use of the separators; but I am not sure but that it was more our fault than the fault of the bees. They are very prolific, breeding even when there is no nectar to gather, and they often gather when other bees are idle. I have this fall secured from Mr. Frank Benton, a Carniolan queen, and shall try crossing the Carniolans with the Syrians. Perhaps we can thus secure a strain with the amiability of the Carniolan, and the business of the Syrians.

Our exhibition the past autumn, thanks to our able secretary, Messrs. Hutchinson, Hunt and others, was very fine, and reflected great credit on our Association and our State. These shows can but do immense good. They show what bee-keeping is, and develop a market as nothing else can. I suggest that we reappoint our committee, and that we ask for still larger premiums, a separate hall in a convenient and accessible location, and that honey in small packages be sold, all through the fair. A neat little pail of honey or comb section thus sold on the fair ground, will influence the market all over the State.

"Pasturage for Bees" is another subject that may well receive our attention. Though it may not be a demonstrated fact, there can be hardly any question but it will pay to plant for bees. Every bee-keeper should scatter motherwort, catnip, figwort, spiderwort, sweet clover, and Rocky Mountain bee plant seed in all the waste places about the apiary. These are harmless plants to the farmer, and, as their presence adds to the

wealth of the country, he is a benefactor who causes their introduction and spread. They are more beautiful than May-weed, nettles, or smartweed, and may well supersede these cumberers of the ground. It is well worth while, too, for our bee-keepers to stimulate the growth of alsike clover. Let us sow it ourselves, and furnish it to our neighbors that they may plant it. Let our bee-keepers see that the ladies have abundance of mignonette in the garden; and ever bear in mind that raspberries gives us a most luscious fruit, which costs very little, and more—furnishes the bees with nectar that equals that of the clovers and basswood, when converted into honey. To be sure, the raspberry, white and alsike clover, and the tulip, comes at about the same time. Yet, who has not noticed that after the clovers will utterly fail to attract the bees, then the raspberry blossoms will be ringing with the joyous hum of our pets of the hive. Plants, like insects, are very susceptible to changes in the weather, and vary in the degree, which the weather effects to modify their functional activity. So success will often vary exceedingly with the greater or less number of honey plants, even though all are in bloom at the same time. In this connection, we all should observe the plants in reference to the soil on which they grow. I have found that while Rocky Mountain bee plant and mignonette do well on light sandy soil, figwort and spider plant do very poorly. It is well to note the natural soil of the plant, and if we wish to change its habit, do it gradually, that the transition be not too violent. Figwort grows naturally on rich, heavy, moist soils. To change it at once to lightest land, is a very abrupt transition.

There are few topics, at present, in which we Michigan bee-keepers are more interested than in that of "foul brood." Probably there is no State in the country in which this fell malady has gained so large a foothold. I have received specimens from Lenawee, Jackson, Livingston, Wayne, Washtenaw, and Montcalm counties. Surely, it behooves us all to become thoroughly conversant with this terrible plague, that we may be ready to grapple with it at its first appearance, should it come among us. The fact that it has jumped the past season from the south to the north part of the State, shows that we are all in danger. As Mr. Muth, who is the advocate of sulcylic acid as a cure, and Mr. Jones, who has faith in, and practices the starvation method of treatment, are to be with us, I will only venture the remark that very likely the rank and file can do no better than to keep a very close watch, and at the very first appearance, practice the extermination method. Experts may cure. The novice will possibly save money and patience if he stamps it out, at the outset, by cremation or burial.

Michigan now has probably the most active and influential State organization in the country. I think she has the greatest number of local organizations (she now has seven) of any

State. We need not wonder then that the editor of one of our largest and most influential bee papers, one of the very best, in fact, in the world, states that he has more subscribers in Michigan than in any other State. Possibly we now have enough local organizations, though it would seem that there might be room for another West of Battle Creek, on the Central. There are now three along the Central railroad, two on a line with Lansing, and two on the D. & G. H. railroad. Besides the one in the southwest, yet to be, there will soon be need of one still further north.

It is certainly for our good, and the general good of our craft, to keep these associations alive and vigorous. As a preventive of "foul brood," I would rather have a wide-awake local society, than all the other methods. It would give the knowledge to diagnose the evil, and would make known all the remedies, and would give the wise discretion in a choice and application of them. Let us see to it that these associations are well sustained, and are kept in close relation with this our State society.

It is a little late to speak of wintering, yet it is always an interesting theme to the apiarist. I will only say that I believe that he who cared well for his bees last autumn, gave them sufficient stores, and has them in a proper cellar, has little to fear. Sugar may be better for winter—surely is better than some honey. That it is better than most honey, I do not believe. Pollen may not, usually will not do any harm. Yet I do not hesitate to say that it is safer to have it omitted in provisioning our bees for winter. This conclusion I came to after a trial of several years. I could theorize as to the cause, but consider the fact more important.

I hope and trust that this will be one of the most interesting and valuable meetings we have ever held. I hope that in our selection of a place for our next meeting, we will go where we are wanted, that proper pains may be taken to thoroughly advertise our meeting, secure a hall, and arrange all the necessary local details.

A. J. Cook.

The election of officers resulted as follows: President, W. Z. Hutchinson; Vice-Presidents, R. L. Taylor, James Heddon and B. Salisbury; Secretary, H. D. Cutting; Treasurer, T. M. Cobb.

Mr. Langstroth then remarked that he had been so kindly received that he felt some embarrassment in speaking. He had made nothing by his invention, but he would rather have the good will of his fellow-men than to be the possessor of untold thousands, made at the expense of others. He spoke of his passionate love for insects in his boyhood, giving many amusing illustrations. He had brought flies back to life that were apparently dead from drowning; had attempted to start ant hills; and was punished for wearing out the knees of his pants in examining ant hills, etc. The reading of Virgil only made him the more cautious, and led him to examine things for himself. Had he possessed

books, it might have been the worse for him, as he might not have investigated so closely. He then gave a history of the invention of the movable frame hive, spoke of the honored dead, of his sickness, etc.

At the close of Mr. Langstroth's address, the building fairly rang with applause.

The following was then passed: *Resolved*, That the editors of the several bee periodicals, and writers on apicultural subjects, be requested to use the word Langstroth in reference to this hive of every style of frame; to say, for instance, "The Simplicity Langstroth," and not the Langstroth.

"Honey-Producing Plants" were discussed, and the outlook was quite favorable.

Dr. Mason: Sweet clover is my favorite honey-plant. There are acres and acres of it in Toledo, even in the busy streets, and one who has never seen it, has but little idea how luxuriantly it grows. The wagon wheels run against it, and scatter the seed. A neighbor of mine obtained 1,000 pounds of surplus honey from sweet clover, and it was gathered quite late in the season.

T. F. Bingham: Sweet clover may be very fragrant when in bloom, but it is no ornament to the streets of a city. Look, for instance, at the streets of Chicago.

Prof. Cook: It is not an ornament in the fall, but neither are other noxious weeds that furnish no honey; if we must have weeds, let them furnish honey.

The question was asked—"Do queens mate more than once?"

Dr. L. C. Whiting: I have watched queens and seen them fly and return with the evidence of having met the drone, and in a few minutes fly and mate again. I had one queen that flew and mated five times before commencing to lay.

Rev. L. L. Langstroth: I, too, have seen the same thing, but have always thought that such queens were not really and fully fertilized until the last time they flew.

The next subject was "Wintering."

Mr. Gillett: I think that early preparations for winter is important. I lose the most bees among those that are packed late in the season.

A. Keppen: My hives are double-walled, and filled with tow. The bottom-board is made in the same manner.

R. L. Taylor: I have wintered my bees successfully two winters, in the cellar. They occupy a separate apartment, and a furnace gives an abundance of ventilation. The temperature is kept at about 40°. Those heavily packed out-of-doors, suffer from dampness. Strong colonies are more apt to breed, and thus bring on dysentery.

Prof. Cook winters bees successfully in a cellar where the water often stands 8 inches deep.

Mr. Benham: I prefer cellar wintering; but taking them out too early in the spring is detrimental.

T. C. Pollock: I prefer cellar wintering. I leave the cellar open until apples freeze near the door, then

close it up. If the outside temperature rises, it will not much affect the cellar if it is kept closed.

Mr. Emigh: I winter my bees in the cellar, and my losses are slight. In the spring I set out one colony, and when that begins to bring in pollen, I put out the rest. My cellar is ventilated by a pipe connected with the stove-pipe.

D. A. Jones: As near as I can recollect, the consumption of honey, per colony, in my cellar, is about 6 pounds. Out of doors it requires 10 pounds more. Carrying bees out for a flight, always brings on dysentery. My bees, confined six months, came out all right. When bees are found clustered tightly, all is well.

Dr. Mason: I agree with Mr. Jones that, when bees are clustered tightly, they are all right. I have wintered bees successfully in different kinds of cellars, and I do not care whether the cellars are wet or dry. Bees that die in the cellar do not have the right kind of food; and the less of any food they consume the better.

Mr. Muth: I want my bees to have from 20 to 30 pounds of honey for winter, and I care not for pollen. I do not think it causes dysentery.

Mr. Jones: The mice pulled the covers from some of the colonies, in one of my bee houses, and those colonies wintered the best.

Prof. Cook: My experience has been the opposite.

Rev. L. L. Langstroth: Moving the combs apart is a great help in wintering. A warm covering, something like a woolen blanket, is a good protection.

Adjourned till 1:30 p. m.

AFTERNOON SESSION.

The Convention was called at 1:30 p. m. President Hutchinson in the Chair. The first topic brought up was: "Comb Foundation." The discussion was preceded by an exhibition of the given press, and the manufacture of foundation. The sheets of wax had become so warm that several had stuck together, and in making up full sheets, several pieces were put together.

Mr. Taylor: I use Babbitt's concentrated lye to keep the wax from sticking to the dies. Wax works best in a temperature of from 70° to 80°. Lye is not disagreeable to bees, as they often come out and sip it up while I am at work.

Prof. Cook: The foundation made here last spring by Mr. Taylor, was certainly very fine, but as some prefer the Van Deusen foundation, and as Mr. Van Deusen is here, we would like to hear from him.

Mr. Van Deusen exhibited a large sheet of foundation. He said that many objected to it on account of its hardness, but such should remember that the heat of the hives soon softens the wax. Others objected to the flat bottoms, but he thought this no more objectionable than the round cell of the Dunham.

Prof. Cook: The Pelham will need mention, especially as it is cheap.

C. F. Muth: I have tried the flat-bottomed and that made by Chas. Dadant, and I see no difference.

Question—"What kind of bees are the most gentle?"

D. A. Jones: Italians are the most gentle; but Syrians crossed with Italians are the best honey-gatherers. There is a difference in the Syrians—from some localities they are gentle, from others they are not. Those from Mt. Lebanon are the best. I prefer to mate Syrian queens with Italian drones.

On "Finding Black Queens," D. A. Jones said: Shake all the bees from the combs into the hive, and set the combs to one side, shake the bees to one side of the hive, and as they start to spread out, and set up their buzzing, the queen will come to the top and start out with those long strides of hers, and she can easily be found.

The question was asked: "Is it true that bees can be wintered on from 6 to 10 lbs. of honey per colony?"

D. A. Jones: Yes, it is true, but they will consume large quantities after being placed upon their summer stands.

Prof. Cook: We have wintered a colony upon 3 pounds.

On motion of H. D. Cutting, W. J. Baxter, of Jancsville, was made an honorary member.

Question—"Shall we influence people to become bee-keepers?" Some said yes; others, no. D. A. Jones gave several reasons in the affirmative. Said that we could not produce as much honey as we could sell.

Prof. Cook agreed with Mr. Jones.

On the "Prevention of Bee Stings," D. A. Jones said: I have found that a person wearing black clothes is more liable to be stung. "Fuzzy" clothing is the kind to wear if you want to be stung. Something smooth like duck, is the best to avoid stings. The first thing a student is told to do, is to singe the hair from his hands and wrists. If you wear a veil you must wear it constantly. If one operator wears a veil, and another in the same yard does not, the one without a veil will receive more stings than he would if the other did not wear one. A straw hat with a wide slouching rim is the best with which to avoid stings.

Adjourned till 7:30 p. m.

EVENING SESSION.

The meeting was called to order at 7:30 p. m., by President Hutchinson, who remarked that Dr. Mason had a comb on exhibition, one-fifth of which was paraffine, and he knew that the Doctor would like to talk about it.

Dr. Mason: I do not know that there is much to say. I tried mixing paraffine with wax, and making the mixture into foundation. Alternate frames were filled with this kind of foundation, and the other frames with pure wax foundation. The bees drew them out and used them just alike. I could see no difference. Myself and neighbors have used such foundation for two years. Paraffine can be obtained whose melting point is about like wax. The time is coming when something must be substituted for wax. I would use it for comb honey if certain that it was a fine article.

D. A. Jones: To detect paraffine or tallow in wax, keep pure wax and the suspected wax at the same tempera-

ture, gradually raising the temperature, and that containing the other substances will melt first. I have tried paraffine, but could obtain no satisfactory results.

J. Van Deusen: I have looked for a substitute for wax. Thought celluloid might answer, but found that it cost \$2 per pound. I found paraffine that would stand a test of 140°, but even that would not answer.

Dr. Mason: I have had paraffine that it became necessary to break into small pieces in order to have it melt as soon as wax.

J. Van Deusen: I presume it would be possible to obtain paraffine whose melting point would be high enough to answer when wires are used.

Dr. Whiting: I have used foundation containing paraffine, and it gave me much trouble. The wax made from such combs might cause the purchaser of it some trouble.

S. T. Pettit: We must soon have a substitute for wax, why discourage trying such things?

D. A. Jones: I have tried almost everything; muslin covered with wax was a failure. An expensive quality of linen paper covered with wax has been a success to a certain extent. Figures, writing, or drawing can be made upon the paper before coating it with wax, and they will show after the comb is drawn and finished. The trouble came in when the bees attempted to thin the septum.

R. L. Taylor had tried mixing resin with the wax, but it was a brilliant failure. The bees neglected it for a long time, and then built drone comb over it.

The report of the committee on resolutions was passed unanimously. It gave thanks to Rev. L. L. Langstroth and visitors from other States; to the proprietors of the hall; the railroads for reduced fares; the local papers for notices, etc.

The Convention adjourned to meet at Lansing upon the second Wednesday after the first Tuesday in December, 1884.

For the American Bee Journal.

Straight Worker Combs without Using Comb Foundation.

G. M. DOOLITTLE.

To have all our combs built true in the frames, so that each comb is as true as a board, is certainly worth working for, to those who handle their frames. If frames are not to be handled, then a box hive is as good as one with frames in it, for all practical purposes. The object of frame hives is to allow of a better control over the inside of the hive than could be done with box hives, and only as these frames are movable, in the fullest sense of the word, is this object secured. We often see combs so bulged or crooked in the frames, that they will not allow of their being exchanged to different parts of the hive, or from one hive to another; in which case the hive containing them can scarcely be called a movable comb hive.

To tell those wishing to know how worker combs can be secured, built

straight and true within the frames without the aid of comb foundation, is the object of this article. I expect many will think it "mistaken economy" to try to get combs without using foundation, but many cannot afford to buy it, and a few, myself among that number, believe that combs can be built as cheaply as the foundation can be purchased and gotten into combs. In a future article I propose to discuss this matter regarding the economy of comb foundation, therefore I will say nothing further on the subject here.

As a starting point toward straight combs, I use a wax guide on the under side of the top-bar of the frame, which is secured by making a straight edge of hard wood, 7-16 thick by 1 inch wide, and $\frac{1}{4}$ inch shorter than the inside of the top-bar of the frame. This straight-edge is nailed to a wide board, and the board so fixed that it inclines enough for the melted wax, (which is to be used to make the guide) to run along the top-bar freely. With a wet sponge, moisten the straight-edge, lay the frame on the wide board with the underside of the top-bar pressed against the straight-edge, when a little wax is turned from a spoon into the upper end of the V shaped trough (which is made by the top-bar of the frame and the straight-edge,) and allowed to run down the whole length of it. Now lift the frame and you have a nice wax guide for the bees to start their comb on. By keeping the straight-edge wet, the wax will not stick to it, and by using a lamp under the dish of wax, it can be so regulated that the wax is kept at the right temperature all the while. In this way guides can be put on very rapidly.

While I have found a guide of some kind an absolute necessity (the above being the best,) I have also found that no guide can always be depended upon, for bees are sometimes very obstinate, and will leave the guide so as to build crooked combs if they do not go directly across the frames. Consequently, it pays the apiarist to look at each colony hived on empty frames while they are building comb, as often as once in 3 days. If any combs are found going wrong, they can be bent back in line very easily, and after the hive is once filled, they are good for a long time, as I never saw one that I would discard on account of age.

The readers of the BEE JOURNAL are aware that I prefer natural swarms, and to best illustrate how I secure combs such as I desire, I will give my management of a swarm. As all my queens have their wings clipped, the swarm is hived by letting them return, previously moving the old colony to a new location and setting the new hive, containing the full number (9) of frames, in its place. In two days I open the hive, and usually find that the bees have made a start in 5 frames. These 5 frames are placed together at one side of the hive, and a division board is placed next to them. This throws the full force on these frames, and they will soon fill them with straight worker comb as a rule, especially if a few sections are placed

over them (as there always should be), so that if any drone comb is built, it can be done in the sections. This also gets the bees at work in the sections quicker than any way I know of. If you get these 5 combs built straight, you will have no trouble in getting the rest so, as they can build them no other way, if placed between two of those already built. If every comb is straight and all worker, such a colony will be a profitable one, and if each colony has such combs, all will be profitable.

No apiarist if he has not more than 3 or 4 colonies, should consider them in proper working order until each comb is a straight worker comb. There is no need of having hives half full of drone comb, and so crooked that they cannot be handled. If we do things at the right time and in a proper manner, our bees will more than pay us for all time spent on them.

Suppose that, instead of working as above, we hive swarms without paying any further attention to them. Swarms issuing when honey is very abundant, will build comb very rapidly, filling their hive in 8 or 10 days, in which case their combs will be apt to be crooked, and at least $\frac{1}{3}$ drone or store comb, which is good for nothing for rearing workers the next season; but is an actual damage, as the drones reared in them will consume a great part of what the workers gather. Such colonies will be unprofitable ones, either for rearing bees or storing honey, just so long as the comb is kept in that condition.

In conclusion, I will say that I have never used 10 lbs. of foundation in brood frames since I have kept bees, but have built my combs as above, and until I am better satisfied that comb foundation pays than I have been from past experiments, I expect to so build them in the future; hence I am not preaching what I do not practice. All I have to recommend the above, is the success I have attained with it, and if any think that it is not "the right way to work," they can pass this article by, the same as if it had not been written. Still I should like to have all the advocates of foundation try one colony as above, by the side of one hived on comb foundation (both hived at the same time), both of which are to be worked for comb honey. Keep the honey each produces separate, and add to the one building its own comb, enough to cover the cost of the foundation used by the other, and see which comes out ahead.

Borodino, N. Y.

For the American Bee Journal.

Syrian Bees as Breeders.

W. Z. HUTCHINSON.

On page 643, Mr. Fayette Lee takes exceptions to some of my statements in regard to Syrian bees. Please allow me to explain. I do not judge of the Syrians' viciousness solely from my own experience, nor from Mr. Lee's, or Mr. L. L. Lowmaster's, or Prof. Hasbrouck's, or Prof. Cook's, or Mr. Jones', or any other single individual experience, but I look at the evidence

in the aggregate. When there are more than 90 practical bee-keepers gathered together, as there was last October at Chicago, and only one of that number has had gentle Syrians, I consider the fact significant. Mr. D. A. Jones himself admitted, at our late State Convention, that the Italians were more gentle than the Syrians, but said there was a difference in the different strains of Syrians, those from Mt. Lebanon being the most peaceable.

Mr. Jones is a queen breeder and a producer of extracted honey, and prefers a cross between the Italians and Syrians, while I make the production of comb honey a specialty, and prefer a cross between the Italians and Germans; we both have good reasons for our preferences.

In regard to their not properly ripening and sealing their honey, did I not explicitly say, "I am aware that this complaint against them is not universal;" but those who are interested in this matter, should turn to the report of the Northwestern Convention for 1882, and read the testimony of E. J. Oatman, upon the point. This point would not be so serious in working for extracted honey.

Perhaps the statement that they will "rear brood so long as a drop of honey remains in the hive," needs qualifying to mean that they will do so only in warm weather. I certainly did not wish to convey the idea that they would continue breeding after cold weather had commenced, but that they would breed from early spring until late in the fall, whether honey was coming in or not.

I have no desire to tear down nor to build up the reputation of any bees, neither do I enter any controversy upon any subject for the sole purpose of defeating my adversary; my only object is to arrive at the truth, and, if in so doing I am "beaten" in my argument, I shall feel grateful to my opponent for pointing out my errors.

Rogersville, Mich., Dec. 15, 1883.

For the American Bee Journal.

"The Pollen Theory"—Facts.

J. M. SHUCK.

Having given the winter condition of bees very close attention for ten years last past, I wish to add to Mr. Kohnke's article in No. 50 of the BEE JOURNAL, the following facts:

1. I have observed that bees do attempt to consume pollen during the winter, when not rearing brood. Mr. Doolittle will here arise to ask how I know they do. I will answer by asking him how he knows his bees eat honey during the winter. I know they eat pollen because it is gone from the cells. I know they eat it, for it is found in their excrement. I have observed that they not only eat pollen when driven to it, but that they attempt to eat the wax. I have repeatedly seen combs thus mutilated.

2. I have seen queenless colonies affected with diarrhoea where honey was short and pollen present; these could not have been rearing brood.

3. I have known queenless colonies, and colonies with queens confined, on granulated sugar syrup, within their hives, out-of-doors for five months, including the worst winter weather; then come out dry, bright, and no sign of diarrhoea, and have seen them do nearly as well on good honey.

4. I have seen bees wintering on ordinary honey stores after long confinement, void their excrement on the combs within the hive, and pollute them as we all know they do without seeing them.

5. I have seen bees wintering on pure cane sugar stores after long confinement, void their excrement over the combs without pollution, it being thin and as clear as water; I have seen this day after day, and have never observed any evil results from it.

Probably T. F. Bingham suggested this pollen theory some 8 or 9 years ago; I think so, but cannot prove it. I know that James Heddon has slashed right and left about this thing for some years, and lately G. M. Doolittle calls for the facts. Lets have them, and be done with it.

Des Moines, Iowa, Dec. 12, 1883.

SELECTIONS FROM OUR LETTER BOX

Packed on Summer Stands.

Last spring I had 15 colonies of bees. Three of them were queenless. I doubled up 4 of the others, so that I had but 10 good working colonies. The season was wet, cold, and unfavorable for rearing and fertilizing queens for my queenless colonies; so I ordered some queens from Kentucky, but did not get them until about the first of July. I unpacked my bees on April 25. One swarm came out April 30; I hived it on 4 frames of comb foundation, and it gave me 45 pounds of honey in two-pound boxes. My bees produced 607 pounds of honey in one and two-pound boxes, and 147 pounds of extracted honey, making in all 754 pounds of clover honey. August was so dry that I got no honey after July. My bees increased by natural swarming to 27 colonies, which I packed for winter on the summer stands, each having 33 to 40 pounds of good clover honey. Wm. Morse.

Rockford, Ill., Dec. 15, 1883.

Bees Starve in the Midst of Plenty.

I would like to give an instance of how easily bees may be starved with plenty of honey near them. A friend of mine had neglected to take the honey boxes off his hives, until about Dec. 1. While removing them, he found where the bees in one hive had taken up their winter quarters in the surplus arrangement; he undertook to drive them below with smoke, but as they did not go readily, he took the honey out, and as there was an abundance of stores below, he supposed they would be all right. But what was his astonishment on opening the hive, a few days later, to find the bees all clustered in the box as natural as life,

but cold and stiff in death's embrace. This was a strong colony, and came through the cold winter of 1882-3 on the summer stand, without any protection. I would say the mercury only indicated 10° below freezing, when the bees starved. S. J. YOUNGMAN.

Cato, Mich., Dec. 15, 1883.

Wintered on Sugar-Candy.

On Nov. 20, 1882, I put into the cellar 23 colonies in Carey's improved hives. I took them out on April 20, 1883, all in good condition, except one which was queenless, which I put with two weak colonies; that left me 22 colonies, spring count. The season was cold and wet. I started queen-rearing on June 1, when the bees were at work on raspberry and white clover. I made 60 nuclei, and reared 100 queens. I sold 40 of the nuclei and 75 queens. I extracted 700 lbs. of white clover honey, and had 300 lbs. of comb honey. I have 42 colonies of Italians, and 38 colonies of blacks, which I bought this fall. These I put into the cellar on Nov. 15; they were generally light, on account of early frost. I gave each 10 lbs. of candy made from granulated sugar and honey (25 lbs. of sugar and 5 lbs. of honey), which makes the best candy I have tried for winter stores. I like it better than honey. The bees do not come out gorged, and have the dysentery in the spring. I keep the cellar as near 45° as possible, and have only one ventilator (a 6-inch stove pipe). Since I tried this method of wintering, I have lost but 8 colonies all told, in 5 years.

A. A. BYARD.

West Chesterfield, N. H., Dec. 17, 1883.

To Bee-Keepers of Iowa.

I want to call together all the bee-keepers of the Cedar River Valley and surrounding territory that may be interested in forming an organization in the interest of modern bee-keeping, and the production and marketing of honey, to meet at Waterloo, Iowa, Feb. 13 and 14, 1884. Do not wait until the organization is formed, but come along and help organize it. Help us make the start, for we need an organization of this kind in this vicinity. Among the prominent bee-keepers of this section, who are anxious to form an association, I may mention J. W. Spaulding, of Charles City; John Bird and Chas. Tracy, of Nashua; O. O. Poppleton, of Williamstown; A. J. Norris and E. A. Starks, of Cedar Falls; J. M. and A. Bennett, of Waterloo; L. L. Triem and Dr. Oren, of La Porte; Samuel August, David Thayer and James Rulston, of Vinton; Robert Quinn, of Shellburg; Thos. B. Quinlan, of Cedar Rapids; E. A. Sheldon and A. R. Blood, of Independence; J. K. Oren and George Black, of Brandon; Wm. Hunt & Son, of Centre Point. All the above named are interested, and a great many more not mentioned, no one of whom have less than 50, and from that up to 300 colonies. We extend an invitation to all outside of this territory, who can, to meet with us. I have mentioned Waterloo, so as to make it central from all directions, and I will send a notice to each of the county

papers along this valley, one or two weeks before the time of the meeting, and try and make arrangements with the hotels for reduced rates during our stay. Remember, bee-keepers, "united we stand, divided we fall."

H. O. McELHANY.

Brandon, Iowa, Dec. 15, 1883.

Wintering on the Summer Stands.

My report for 1883, is—a light crop. I commenced in the spring with 35 colonies—increased 66 per cent. I obtained 2,150 lbs. of extracted honey, and have some 300 lbs. left in the surplus combs for spring stimulating. They winter on summer stands, part in 2-story hives with the top story filled with oat-straw, and part in one story with no protection, except a quilt and 5 thicknesses of paper spread on the frames, with a tight-fitting cover. I formerly wintered my bees in the cellar, and prefer the cellar for a cold winter; but I prefer the summer stands for a warm winter. A. S. ENSON.

Martinsville, Mo., Dec. 11, 1883.

Fair Honey Harvest.

Bees have done well in this part of the State, during the past season, especially the early part, which was very good up to the first of July, when the dry weather cut off the flow for the season, so far as surplus was concerned. The bees gathered enough honey to keep up brood rearing and enough for winter stores, with those that took interest enough in the business to take care of their late swarms and return them to the parent colony. But those that were hived in empty hives did not gather enough, and they will be numbered with the dead when spring comes. My 34 colonies of bees are in winter quarters in good condition, and with honey enough to last until fruit bloom. GEE. COLE.

Freeport, Ind., Dec. 18, 1883.

Got only half a Crop.

As long as I keep bees I never want to be without the BEE JOURNAL. Bees did not do as well here last season as the year before. I think I shall get about half a crop, compared with the season of 1882. I had 38, spring count—increased 4; 42 this fall (I worked against increase); all are well supplied with honey now. I have sold my comb honey at 16 cents mostly, and extracted at 12½ cents. My crop will be about 2,000 lbs., of which I still have 1/3 on hand. My supplies came so late that I have them all on hand for next year; they were 2 months coming from the time I ordered them. Weather is very pleasant here—more like spring than winter, so far. Bees were flying nearly every day. I have 3 colonies that I have taken from the neighbors that were going to kill them. I have for several years took such, and have always wintered them as well as any. I took 13 colonies last fall; doubled them down to 6; I gave them frames from my other colonies, of sealed honey, and they are all right for winter, just the same as any colony. I use the Langstroth hive and am well satisfied with it. W. H. GRAVES.

Duncan, Ill., Dec. 14, 1883.

Convention Notices.

The 15th annual convention of the Northeastern Bee-Keepers' Association will be held in the City Hall at Syracuse, N. Y., on the 22, 23 and 24 days of January 1884.

This will be the largest and most interesting convention of bee-keepers ever held in America. Many of the most scientific apiarists in the country will take part in the discussions. The programme is completed, and comprises all the interesting topics of the day. The question box will be opened each day, and the questions answered. All are invited to send in questions.

Implements and other articles of interest for exhibition will be received and properly arranged. It will pay any bee-keeper to go a thousand miles to listen to the discussions. By hearing and seeing, you will obtain much more knowledge than by reading. Five hundred bee-keepers will be in attendance. Reduced rates of board at hotels have been secured. All are invited.

GEO. W. HOUSE, Sec.

W. E. CLARK, Pres.

Notice is hereby given that the Nebraska State Bee-Keepers' Association will meet in annual session at Lincoln, Neb., Wednesday, Jan. 9, 1884, at 2 p. m., in the Y. M. C. A. rooms on Tenth street, between Q. and P., just east of the Government Square.

We have the promise of some eminent apiarists from other States to be with us, and also expect to have one of the largest displays of apianian supplies ever gathered together in the State. Each person attending, is requested to bring something to exhibit or show, to the edification of bee-keepers and others. Past members are earnestly requested to renew their membership, and all others are cordially invited to come in with us.

The ladies having been well represented at our past meetings, we certainly expect a larger attendance this session than ever before. All those not attending will surely miss a good time, for we expect the largest gathering, and also the most enthusiastic meeting of practical bee-keepers ever held west of the Mississippi river.

We have succeeded in making very satisfactory hotel arrangements. Two dollar hotels have offered \$1 rates. All bee-keepers desiring to attend can obtain certificates entitling them to excursion rates over the B. & M. and V. P. railroads by applying at any time previous to Jan. 6, to M. L. Trester, Secretary of Nebraska Bee-Keepers' Association, Greenwood. Please apply immediately.

M. L. TRESTER, Sec.

T. L. VAN DORN, Pres.

The annual meeting of the Indiana bee-keepers will be held at Indianapolis, Jan. 15 and 16, in the Agricultural rooms corner of Tennessee and market streets. A cordial invitation is extended to all.

F. L. DOUGHERTY, Sec.

The Ohio bee-keepers will hold their annual convention in Columbus, O., Jan. 14, 15 and 16, 1884. All interested in bee-culture are invited. The following subjects will be discussed: "How to winter bees successfully." "Are the new races of bees a success?" "What can we do to prevent adulteration of honey?" "How to create a home market for honey." "How many colonies can be kept in one locality?" "Can we do without separators?" "Which are best, deep or shallow frames?" "What shall we do with second swarms?" "How many brood frames are necessary in a hive?" "Which is the most salable section, one-half, one or two pounds?" "Is it advisable for all bee-keepers to adopt a standard size of frame?" "What is the most desirable width of sections?"

The above questions will be discussed by eminent men, such as Rev. L. L. Langstroth, Dr. Besse, S. D. Riegel, C. F. Muth, A. I. Root, of Medina, and others, and in addition to the above, Prof. Lizenby, of the Ohio University, will deliver a lecture on "Honey-producing plants;" also Mrs. Jennie Culp will read an essay.

C. M. KINGSBURY, Sec.

The Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association, will hold its annual meeting in Temperance Hall, Freeport, Ill., on Jan. 15 and 16, 1884.

J. STEWART, Sec.

Rock City, Ill., Nov. 30, 1883.

The 5th annual Convention of the Northeastern Ohio and Northwestern Pennsylvania Bee-Keepers' Association, will be held at Jefferson, Ohio, Jan. 16 and 17, 1884. All are cordially invited.

C. H. COON, Sec.

New Lyme, O., Nov. 26, 1883.

Owing to the death of our Secretary, Mr. T. Brookins, please announce in the BEE JOURNAL that the annual meeting of the Champlain Valley Bee-Keepers' Association, will meet in the parlors of the Addison House, Middleburg, Vt., the second Thursday in January, 1884.

J. E. CRANE, Pres.

The Bee-Keepers' Association of Central Illinois, will meet in Bloomington, on Jan. 9, 1884. All are cordially invited to attend.

JAS. POINDEXTER, Sec.

The annual meeting of the Cortland Union Bee-Keepers' Association will be held in Cortland, N. Y., on Tuesday, Jan. 8, 1884.

M. C. BEAN, Sec.

A meeting of the bee keepers of Des Moines Co., Iowa, will be held on the second Tuesday in January, at 10 a. m., for the purpose of organizing a county bee-keepers' association, at Middleton, Iowa, in R. C. Crawford's Hall. JOHN NAU, FRANK MELCHER, A. M. BALDWIN, W. R. GLANDON, Committee.

The Southeastern Michigan Bee-Keepers' Convention will be held at Adrian, Mich., in the Plymouth Church Chapel, Jan. 23, 1884; morning, afternoon and evening session.

H. D. CUTTING, Pres.

H. C. MARKHAM, Sec.

The Eastern New York Bee-Keepers Union, will hold an annual Convention in the Agricultural Hall at Albany, N. Y., on Tuesday, Wednesday and Thursday, Jan. 3, 8, 9 and 10, 1884. We invite exhibition of hives, extractors, implements for the apiary, and all apianian supplies. Time will be given for exhibition and examination, and testimonials awarded. There will be speeches and essays on important topics from prominent apiarists, and questions on interesting subjects will be discussed. A general invitation is extended to all interested in apiculture. S. VROOMAN, Pres.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
Monday, 10 a. m., Dec. 24, 1883. }

The following are the latest quotations for honey and beeswax received up to this hour:

CINCINNATI.

Extracted honey brings 7@9c. on arrival. Best comb honey, 16@17c. in small sections. BEE-SWAX—Is of ready sale at 28@30 on arrival. CHAS. F. MUTH.

NEW YORK.

HONEY—White clover and basswood in 1 and 2 lb. sections, 17@22c. Dark and second quality, 14@15c.; extracted white clover in kegs and barrels, 9@10c.; dark, 8@9c. BEE-SWAX—Prime yellow, 27@29c. H. K. & F. E. TRUBER & CO.

CHICAGO.

HONEY—The market remains without change from that of last week. Dealers and retailers buy only enough to supply the demand for present use. It is impossible to place lots, or entire shipments, owing to the reluctance of dealers to buy in advance of immediate wants. Prices obtained for white comb in 1 lb. sections, 18@20c.; 1½ and 2 lb., 15@16c., according to beauty of same. Extracted honey, 8@10c. per lb., according to color, body and flavor.

BEE-SWAX—Yellow, 33c.; medium, 28@30c. R. A. BURNETT, 161 South Water St.

KANSAS CITY, MO.

HONEY—Market is active and receipts liberal for comb honey, prices ruling from 18c. for choice 2 lb. sections, and sales of a few small lots of choice 1 lb. sections at 19c. Extracted in fair demand at 8@10c., according to quality.

JEROME TWICHELL, 314 Walnut Street.

SAN FRANCISCO.

HONEY—There is some local demand for extra white comb and such could be placed at good figures, but there is an absence of inquiry for all other descriptions. Fair comb was offered at 10c. A sale of extracted of medium quality was made at 6c. White to extra white comb, 15@20c.; dark to good, 9@11c.; extracted, choice to extra white, 7@7½c.; dark and candied, 6@—

BEE-SWAX—Wholesale, 27@28@30c. STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Comb met a fair local demand at 15c. to 18c. per lb. for choice; strained and extracted dull at 6@7c.—in small cans and fancy pkgs. at 10c. BEE-SWAX—Firm, at 28@30c.

W. T. ANDERSON & CO., 104 N. 3d Street

CLEVELAND.

HONEY—Honey continues in excellent demand, as reported last; every lot of choice white comb is taken up as fast as it comes at 18c. in quantity for 1 lb. sections, and an occasional sale at 19; in a very few instances only, 20c. has been reached. Broken lots and second quality is very slow sale. For extracted there is no demand.

BEE-SWAX—Is eagerly inquired for at 28@30c., but none to supply the demand.

A. C. KENDEL, 115 Ontario Street.

BOSTON.

HONEY—Our market is very quiet on honey. We quote 16@18c. for best 2 lb. sections—18@20c. for best white 1 lb., and 10c. for extracted.

BEE-SWAX—We have none to quote. BLAKE & RIPLEY, 57 Chatham Street.

Special Notices.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

For safety, when sending money to this office get either a post office or express money order, a bank draft on New York or Chicago, or register the letter. Postage stamps of any kind may be sent for amounts less than one dollar. Local checks are subject to a discount of 25 cents at Chicago banks. American Express money orders for \$5, or less, can be obtained for 5 cents.

We wish to impress upon every one the necessity of being very specific, and carefully to state what they desire for the money sent. Also, if they live near one post office, and get their mail at another, be sure to give us the address we already have on our books.

Subscription Credits.—We do not acknowledge receipt of each subscription by letter. The label on your paper, or on the wrapper, shows the date to which your subscription is paid. When you send us money, if the proper credit is not given you, within two weeks thereafter, on your label, notify us by postal card. Do not wait for months or years, and then claim a mistake. The subscription is paid to the end of the month indicated on the wrapper-label. This gives a *continual* statement of account.

How to Create a Market for Honey.

We have now published another edition of the pamphlet on "Honey as Food and Medicine," with more *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price *still lower*, to encourage bee-keepers to scatter them far and wide. Single copy 5 cents, postpaid; per dozen, 40 cents; per hundred, \$2.50. 500 will be sent postpaid for \$10.00; or 1000 for \$15.00. On orders of 100 or more, we will print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit. Try it, and you will be surprised.

Letters for publication must be written on a separate piece of paper from items of business.

Our New List of Premiums.

Getting up Clubs for 1884.

To increase the number of readers of the BEE JOURNAL, we believe, will aid progressive bee-culture and help to elevate the pursuit. We, therefore, offer the following premiums for getting up clubs:

While no subscription to the BEE JOURNAL will be taken for less than the regular advertised prices (viz.: Weekly, \$2.00; Monthly, \$1.00),—any one getting up a club of two copies, or more, may select from "OUR BOOK LIST" anything therein named, to the amount of 15 cents for every dollar *they send direct to this office*, to pay them for the trouble of getting up the club; and these books will be sent, postpaid, to any address desired.

For a club of 3 Weekly or 6 Monthly and \$6.00, we will make an *additional* present of a Pocket Dictionary, bound in cloth, containing 320 pages.

For a club of 5 Weekly or 10 Monthly, (or a mixed club of both,) with \$10, we will, in addition to the 15 per cent, present a copy of the AMERICAN "POPULAR" DICTIONARY, comprising every word in the English language that enters into speech or writing; it contains 32,000 words and phrases, 670 illustrations and 512 pages; it is nicely bound in cloth, and will be sent by mail, postpaid, to any address desired.

For a club of \$20, for 10 Weeklies, or an equivalent in Monthlies, we will present, besides the 15 per cent, in books, a tested Italian queen, by mail, postpaid.

Subscriptions for two or more years for one person, will count the same as each year for a different person.

For a club of 100 Weekly (or its equivalent in Monthlies), with \$200, we will send a Magnificent Organ worth \$150. See description on page 614 of the Weekly for Nov. 28, 1883.

Do not let your numbers of the BEE JOURNAL for 1883 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

A correspondent asks if any one may select a binder for the BEE JOURNAL, among the books given as Premiums for getting subscribers we reply, yes; any book or binder we keep for sale, may be selected by those who get up clubs.

THE AMERICAN POPULAR DICTIONARY.

CONTAINING

EVERY USEFUL WORD IN THE ENGLISH LANGUAGE,

With Its Correct Spelling, Proper Pronunciation, and True Meaning.

ALSO, A VAST AMOUNT OF

ABSOLUTELY NECESSARY INFORMATION UPON

Science, Mythology, Biography, American History, Constitutions, Laws, Growth of Cities, Colleges.

Army and Navy, Rate of Mortality, Land Titles, Insolvent and Assignment Laws, Debts, Rates of Interest, and other Useful Knowledge.

BEING A PERFECT LIBRARY OF REFERENCE IN ONE HANDY VOLUME.

512 pages; Cloth; Gilt; Illustrated.

This Dictionary is our Premium for a Club of 5 subscribers to the Weekly (or its equivalent to the Monthly), in addition to other Books selected from our Catalogue to the amount of \$1.50; all by mail, postpaid.

A POCKET DICTIONARY

Containing 320 pages, and over

25,000 Words, Rightly and Plainly Defined

To make the pronunciation easily understood every word is phonetically re-spelled, and the syllables and accents made perfectly plain, so that no one who consults this book can miss the proper word to use, and giving it proper pronunciation.
